Flower Sticks.—Prunings of Apple trees make the best supports with which I am acquainted for Carnations and similar plants. They are straight, strong, and last for three or four years. They answer better than hazel, and should always be saved for such purposes.—G. NOAKES, *Mounthfield Court*.

Picea cephalonica in Perthshire.—A specimen of this beautiful Conifer in the pleasure-ground at Dupplin Castle, measures 50 ft. in height. Its shape is all that could be desired, and taken altogether it must be considered to be one of the finest specimens of its kind in Scotland.—W. LAUREN, *Lynwood, Alce.*

Primulas.—In that beautiful and accurate work, "Maunzie's Botanic Garden," which contains many faithful representations of hardy plants now seldom seen but well deserving a place in the mixed border, at Vol. II. (p. 356) will be found *Primula cortusoides*, and at Vol. IX. (p. 860) *P. amœna*, and several other varieties.—WINTOX.

Hardy Climbers.—Whilst passing some cottages near Norwood Cemetery the other day, I saw a plant of *Passiflora cœrulea*, trained up the front of a cottage, very heavily laden with fruit.—I have never, indeed, on any previous occasion, seen one so profusely and regularly covered with fruit out-of-doors as this was, and, owing to its having the colour of a *Magnus Bonum Plum*, its appearance was strikingly effective.—E. BENNETT, *Rohley*.

The Huon Pine (*Dacrydium Franklinii*).—Perhaps it may not be generally known that sprays of this beautiful Pine do exceedingly well for dinner-table decoration. I lately saw them used with good effect in a trumpet-shaped glass centre-vase. They were placed all round the mouth of the trumpet, in which were various kinds of flowers and foliage, their graceful pendent forms producing a beautiful effect. They have also the good property of keeping fresh for several weeks together.—W. LAUREN, *Lynwood, Alce.*

"This is an art

Which does mend nature: change it rather: but

THE ART ITSELF IS NATURE."—*Shakespeare.*

PREPARING PLANTS FOR THE FLOWER GARDEN.

THERE are three classes of plants now in general use in modern flower gardening, viz., tender, half-hardy, and hardy, and it would be difficult to describe which of the three divisions contained the most numerous varieties now in favour. The hardy section, happily in the ascendant, embraces a goodly list; the half-hardy, though still in large numbers, are resigning their long monopoly; while the tender section is subject to severe restriction from the antagonism of climate and locality, numerous though the claimants have lately been for a place, especially among sub-tropical plants. In the last section may be found a few of the most effective subjects we have for massing and for the intricacies of carpet bedding now in fashion. One or two *Coleuses*, several *Alternantheras*, the variegated *Mesembryanthemums*, *Iresines*, *Kleinia repens*, &c., are very generally used. Starting now with half-a-dozen good old plants of *Coleus* in 4-in. pots, and persevering, as cuttings and space increase, by bedding time (the second week in June) several thousands of good plants may be ready. The best way to keep *Coleus* through the winter is to have a few old plants pot-bound placed high up near the light on a shelf in the stove, and refrain from an overdose of water, or else in a low pit close to the hot-water pipes and glass. A joint with a leaf attached will form a plant; run the knife down the stem between the buds, dividing the node in half; of course, the stock plants must not thus be separated at first, but must be potted on in spring and forced into growth. *Coleuses* are most expeditiously struck in pans of very wet sand set on any warm surface, such as the hot-water pipes or any fermenting material; later in the season (about April) they may be struck rapidly in the temperature of a Cucumberhouse without bottom-heat. *Coleuses* may generally be left to the last, as after the half-hardy plants have been placed in the open air, the glass will be at the service of the *Coleuses*. *Alternantheras* are not quite so easily managed; still they may be propagated with great facility with a little attention to their wants. *A. amœna*, which is the most delicate, can be got up with ease in autumn by planting a dozen plants of it out in a warm pit in August and giving them abundance of water, when they will grow very freely; having struck the cuttings in pans of wet sand in the same pit, transplant them into store pans for the winter, and arrange them on a high shelf in the stove. The stock of *Alternantheras* may be kept up from year to year by lifting a quantity of the old plants early in the autumn, shaking all the soil from them, and packing them closely in pans or shallow boxes with very little soil. Place them after one watering in a close, warm pit to cause them to root afresh, when they should be moved to a shelf in the stove near the glass. About the end of March they should be divided, and placed in shallow boxes or pans; every small piece with a root will grow; heat them briskly in a moist pit, and, notwithstanding their flowering, they will make rapid growth and be strong, healthy plants by June. It is waste of labour to pot *Alternantheras* in private gardens; of course, the stock may be increased in spring by cuttings, the same as recommended in autumn, but the plants will not be so large. *Mesembryanthemum cristalinum variegatum* will strike in September, inserted in boxes with *Geraniums* without any protection whatever, in the open air. Two or three boxes or pans a foot square will supply thousands of cuttings in spring. It requires to be wintered in a warm place, with a better heat in spring to push it on expeditiously. *Kleinia repens*, though a succulent, must be managed in a similar way to the *Alternantheras*; it is a diminutive plant, and must be got up in quantity, and planted close to produce effect—as a setting for *A. amœna* it is exceedingly neat; it is, however, comparatively hardy, and will winter quite well in a dry orchard or Peach house from which frost is nearly excluded. The plants may be simply

packed together as they are lifted from the beds in autumn on the surface of the soil without any planting whatever, and may remain until March. Damp is their great enemy; a slight shrivelling of the foliage is of no consequence. In March they may be cut up into small pieces like *Alternantheras*, and placed thickly in pans or boxes in a dry heat, where they will soon make healthy plants; cuttings may also be taken off as they grow, and a little more moisture will benefit them as the days lengthen; they may be made up to May, with the certainty that the plants will be fit to go out in June. *Iresines* should be managed exactly like *Coleuses*. A cold pit is suitable after the 1st of May by husbanding the sun's heat. Among succulents whose popularity as carpet-bedding plants is now established, several of the tender sorts are propagated with the greatest facility: *Echeveria metallica*, in the young state, is one of the best; it should be raised from seed every season; a single plant grown under glass will yield abundance of seed; indeed, a few pods will be sufficient for thousands of seedlings. Sown in September, in pans, on a smooth surface of light sandy loam, and without any covering; dip the pan with the soil and seed gently in water until the soil is quite moistened, not allowing the seed to be covered by the water, and place the pans in a north house, with the temperature ranging about 50° at night, or in a shaded pit, covering them with a pane of clean glass. In a week the seedlings will make their appearance in abundance; the glass should not be removed for a few weeks until the little plants have gathered strength; when fit to handle they should be transplanted into other pans, $\frac{1}{2}$ in. apart, and grown near the glass in a warm house; pot them in spring, and place them in a close pit. Finely coloured clean plants, 4 in. across, will be ready by bedding time; we annually throw our old plants on the rubbish-heap in October. *Sempervivum tabuleforme*, a more tender plant, is raised in the same way: if a few plants run to seed in the beds in summer, unless it be very early, they should be lifted, potted, and placed in the greenhouse to ripen their seeds, and if these be sown at once in a north house, a plentiful crop of seedlings will be the result, and be fit for the flower garden by the following May, if they be grown on. *Pachyphytum bracteatum* is one of the most distinct and neat of tender succulents, of a pinky glaucous colour, and comes readily from seed sown as recommended for *Echeveria metallica*; from one spike of seed gathered from a plant in the open air, I have raised more than 1000 plants. It is slow work propagating from leaves, although larger plants can be had by this means in a shorter time than from seed, which should be sown in the autumn, just after it has ripened; winter it when young in an intermediate house, and give little or no water until the spring. *Echeveria secunda glauca* is hardier and more accommodating than the above, and is readily raised from seed in the same way; it varies much, however, from seed, and a careful selection should be made of the best from which to raise the stock from off-sets. It may with some risk be wintered on ashes out-of-doors, at the foot of a south wall, but the safest plan is to pack it closely on the floor of an orchard or Peach house until April, when it may be planted out where it is to remain, or on a border provisionally. The neat and distinct cherry-coloured *Sempervivum triste*, forming a good contrast in colour to the last-mentioned, and said to be hardy, can also be raised in quantity from seed; from a pinch sown a week ago we have the seeds germinating in hundreds, perhaps thousands. I anticipate this will be much in demand as a contrasting succulent to *Echeveria glauca*; it makes offsets freely, but this mode of propagation is slow compared with that of seeds. Among the many half-hardy plants used in carpet bedding, *Crystal Palace Gem* is undoubtedly the best among *Geraniums* for a yellow-foliaged plant; the stock of it having been struck in autumn, propagation may now go on by inserting the cuttings singly in small pots, and placing them in a warm pit near the glass. Small healthy plants are more useful for carpeting than larger ones; the whole stock of *Geraniums* may now be increased in the same way if desired. Flower of Spring and Bijou still hold a good place as white-foliaged varieties, also *Mangles' variegated* is indispensable. Among scarlets I know of nothing better than *Charles Casbon*, and *Violet Hill* as a flame-coloured scarlet. *Calceolarias* having been struck and wintered

in sufficient quantity in cold pits will very shortly require to be transplanted into turf-pits, 4 in. apart, with some slight protection. The best yellow is a very old and healthy sort, called Gaines' Dwarf; I have never yet seen it go off with disease, even when aurea floribunda and such broad-leaved sorts have been well-nigh decimated. The next best yellow is Golden Gem, a dwarf kind and vigorous in habit. Rich soil and early planting in the beds, while the soil is yet cool, is the best antidote for Calceolaria disease, a hot dry planting time being always destructive to their health. Pyrethrum Golden Feather should be raised from seed every spring and grown in a cold pit in the open soil like Lettuces at the end of April; grown rapidly it makes much better plants by the carpeting time than if sown in March in heat, and nurtured on the slow principle, besides running much earlier in the season to seed. Lobelias, of all sorts, are also much better if not sown too early and grown on quickly; two weeks in May will do more for them than a month in March and April; they also are liable to become seedy too soon if forced in heat. Tagetes signata pumila also comes under the same category; it should not be sown before April; the same remarks apply to Stocks and Asters. The hardy carpet-bedding plants may now be propagated if not already done. *Stellaria graminea aurea* may be cut into small pieces with a little root attached, and inserted in close lines in the open ground, or cuttings may be taken and struck in heat, afterwards planted out to strengthen in a cold frame. *Violas* may now be broken up small and planted, or cuttings made and inserted thickly under hand-lights or in a cold frame on a slight heat, such as a bed of leaves. Those neat-growing Grasses, the *Festucas*, should be divided and planted in nursery lines, small plants being much neater and more easily worked than large ones. The Variegated Thyme may be similarly treated; it strikes freely at this season. All the various hardy *Semprevivums*, such as *montanum*, *glaucum*, *arenarium*, *californicum*, *globiferum*, *arachnoideum*, &c., should now be divided and planted out singly to strengthen before their final bedding time. The same remark also applies to such *Sedums* as *corsicum*, *lividum*, *glaucum*, *acre aureum*, *elegantis*, &c. Many of the Saxifrages are exceedingly neat for carpeting—dark green, such as *hypnoides*, *hirta*, *moschatum*; light green, *Malyi*; or the many varieties with crusted foliage, like *Stansfieldii*, *crustata*, *Aizoon* minor. *Thymus corsicus* is a very neat green plant for carpeting little slopes in designs, and every fragment will grow. The pretty *Antennaria tomentosa* should now be separated, in order to be more easily moved in May, as it greatly dislikes being handled in hot weather. These constitute some of the most popular bedding plants belonging to the three sections to which I have alluded. W. D. C.

Planting Ranunculuses.—It may be well to remind our readers that this is the best time for planting this beautiful flower. It likes a loamy soil, and that on which some care in preparation has been bestowed is the best for the tubers. The manure should be old, well-worked, and easily incorporated with the soil; which, as regards the upper layer, should be fine, and free from stones. Plant the tubers $1\frac{1}{2}$ in. deep, and 5 in. apart from each other. Press them firmly into the soil, in order to secure their position and freedom from disturbance by worms, which are their great enemies. If the soil be heavy, a little silver sand may be placed on the spot where the tubers are planted, but this is not requisite in light soils. After planting, the surface should be well raked if the weather be fine, and when dry be gently beaten with the back of a spade. As the leaves protrude through the surface, care should be taken that holes formed in this way should be stopped by placing the soil close round the collars of the plants to exclude March winds.—C. TYSO, *Wallingford*.

LORD WINMARLEIGH has presented a petition to Parliament from landowners and others in the manufacturing districts, praying for the amendment of the laws relating to noxious vapours. His lordship, alluding to the disastrous effect of the increased discharge of noxious vapours in destroying vegetation, stated that in some districts the woods in July presented the appearance of trees in mid-winter, and that land was being rendered gradually valueless. Great injury has already been done to nurserymen and others in certain localities, and legislation in reference to the matter is everywhere acknowledged to be greatly needed. The Duke of Richmond admitted the existence of the evil, but was not at present prepared to submit a remedy.

NOTES OF THE WEEK.

—At the meeting of the Royal Horticultural Society, held at South Kensington, on Wednesday last, Mr. Bass exhibited a strikingly beautiful specimen of *Phalæopsis Schilleriana*, bearing a branched spike fully 5 ft. in height, on which we counted seventy-four fully expanded flowers of good form and substance, and brightly coloured. We have seen larger plants than this was, and spikes bearing a greater number of flowers, but we never remember to have met with this *Phalæopsis* in a more vigorous and healthy condition, and we hope that the Council will award it the Davis medal as suggested by the Floral Committee—a mark of distinction which it well deserves.

—A WELLINGTONIA, growing in the pleasure-grounds at Dupplin Castle, in Perthshire, measures fully 48 ft. in height, and has a stem nearly 10 ft. in circumference at the base. In 1857, when it was planted, it was 3 ft. in height, and every year since it has been surface-dressed with machine-cut Grass.

—THE rare *Lilium polyphyllum*, hitherto only known to the majority of cultivators by the figure given of it in Royle's "Illustrations of Himalayan Plants" (plate 388), has been imported by the Colchester Bulb Company. It produces lax spikes, each of which bears from six to ten flowers of a yellow colour, spotted with vinous purple.

—MM. DE LUYNES AND FRIL, in the "Comptes Rendus," state, in reference to the toughened glass, which has of late been attracting so much attention, that on attempting to cut it with the wheel, drill, or file, it almost invariably bursts after the manner of a Rnpert's drop. A disc of the toughened glass could be drilled at its centre without breaking, but it breaks if pierced at any other point.

—A HOUSEFUL of *Eucharises* at the Exeter Nursery is now well worth seeing. It is what is termed half-span roofed, 43 ft. in length, 14 ft. in width, and 6 ft. in height, facing the south-west, and it contains 200 plants, in 8-in. pots, of this showy *Amaryllidaceous* plant, each of which is now carrying four or five spikes of bloom, producing a display rarely met with at this season of the year.

—AMONG Orchids more than ordinarily beautiful now in flower in London gardens, we have seen the following during the past week. In Mr. B. S. Williams' collection, at Holloway, were some strikingly fine varieties of *Dendrobium Wardianum* and several excellent specimens of the rare *Cypripedium Dayanum*. In Mr. Michael's garden at Highgate, we found a very fine form of *Oncidium Weltoni*, and one of the best-grown collections of *Phalæopsis* which we have ever seen, some forty or fifty plants of *P. Schilleriana*, *P. amabilis*, and *P. grandiflora*, being all at the present time in full beauty. One of the best of all Orchids for basket culture is the old *Dendrobium Pierardii*, which is now very effective in Messrs. Rollison's nursery at Tooting, its pendent pseudo-bulbs being in some cases nearly a yard in length, and perfect wreaths of creamy, rosy, lilac-tipped flowers. The rare *Phalæopsis Veitchii* is now producing a spike in Messrs. Veitch's nursery at Chelsea, and apart from its beauty, it is interesting as a natural hybrid between *P. rosea*, which it most resembles in colour, and *P. amabilis*.

—MR. MAX LEICHLIN writes to us from Baden-Baden, as follows:—This winter has been a very severe one everywhere throughout middle Europe, and, therefore, plants out-of-doors have had a rather severe test as to their hardiness. Among others in my rock garden I had planted *Cereus viridiflorus* and *C. phœnicus*; also *Opuntia humilis*, *missouriensis*, *leucospina*, and others, all of which have stood a considerable amount of frost; neither snow, nor thaw and alternate freezing, have had any effect on them; they are perfectly healthy, and have already begun to assume their natural green tints. Although these Cacti are not remarkable as regards showiness, yet, when planted here and there in a rock garden, they produce a grotesque effect, and deserve to be more grown in England than they generally are. If placed at the age of some rock the *Opuntias* overhang it after a year or two; the *Cereus phœnicus*, which grows to a height of 5 in., has long whitish spines and small yet beautiful carmine flowers with green anthers.

—THE thirty-third Anniversary Festival in aid of the funds of the Gardeners' Royal Benevolent Institution will take place this year at the Albion Tavern, Aldersgate Street, on Friday, the 30th June, when Dr. Hogg, one of the Vice-Presidents, will take the chair.

—M. LAVALLÉE, the distinguished horticulturist, states that the common Water-cress and the American Water-weed do not like growing in the same places; and that if the Water-cress be introduced into a brook where the American pest is growing, the latter soon perishes.

THE FRUIT GARDEN.

RENOVATING OLD PEAR TREES.

It often occurs, in long-established kitchen gardens, that old horizontally-trained Pear trees are unfruitful, except at the points of the branches, a circumstance mainly attributable to the branches in the centre becoming covered with thick wood spurs. Root-pruning, in the case of trees with stems 10 in. and upwards in diameter, would for the most part end in failure; and if fruitfulness were induced in that way, in most cases the produce would be small and worthless. To grub up such trees, make fresh borders, and re-plant young ones, would take more time and cost more than many can afford; and, as I hope to prove, such a course is unnecessary. It is

Fig. 1.—First year of the process of renovation.

better to renovate the old trees in the following manner:—Let a commencement be made by operating on the two lowermost branches, *i. e.*, one on each side of the stem. With a small pruning chisel and mallet neatly remove from these all the old spurs, being careful not to injure more of the bark than may be necessary. Then cut off close to the main stem the next tier of branches. If this be done in winter, or before the trees start into growth in spring, in all probability the two bottom branches will throw out a quantity of young shoots, from buds that would otherwise have lain dormant. These should all be rubbed off, except such as stand a foot apart, selecting those that come from the upper side of the branch, and nailing them to the wall in a vertical position, as shown

Fig. 2.—A renovated tree, four or five years old.

in fig. 1, which represents a tree at the end of twelve months from the commencement of the process of renovation. At this time, if any of the trees operated on be naturally weak-growing varieties, I would advise the main stem to be cut off at *a*, using a sharp saw for the purpose; cut in a sloping direction, and cap over the cut with a piece of thin sheet lead to keep out wet. In the case of strong-growing varieties, it is not advisable to cut off the main stem until the second or third year, as the young vertical shoots do not get so well ripened or furnished at the bottom with spurs as they would if the upper branches be left on for a time to take up the superabundant sap; but, when allowed to remain, it is necessary to keep the summer growths well pinched back, in order that they may not unduly rob the young upright ones. The subsequent treatment consists in keeping the latter nailed

up to the wall, and, if the main stem be not cut off, in removing the old horizontal branches (as may be required) to give the young wood room, taking care also to get the wall equally furnished by encouraging the weak shoots and checking the growth of the strong ones. If all go on well, and the wall be not more than 10 or 12 ft. in height, in four or five years at most it will be furnished with bearing branches that will produce good fruit for years, and also have a fine appearance. Fig. 2 represents a tree renovated in the manner just described. Walls exceeding 12 ft. in height are more expeditiously covered by leaving two sets of horizontal branches, as in fig. 3, cutting off the spurs and training up young growths as described above. In this case it will be noticed that the vertical shoots from the upper branches have not so much space to cover as those from the lower ones. This is necessary in order to get an evenly-balanced tree, it being a well-known fact that the sap naturally flows most to the top. If the original varieties be not satisfactory, it is easy to bud or graft the vertical shoots with better sorts; and, should more than one variety be put on a tree, it is best to work the weakest growers in the centre and the strongest towards the points. I find budding the best plan to adopt, inasmuch as it can be done the first summer after commencing operations, by inserting the buds on the lowermost parts possible of the upright growths. I have put as many as 120 buds on one tree, and have seen them make growths a yard long the year after budding. In budding Pears, it is best not to remove the small portion of wood that is taken off with the bud, as many do in Rose-budding; but, with this exception, there is

Fig. 3.—Method of covering walls more than 12 ft. high.

no difference between the two operations, and anyone who can successfully bud Roses will find no difficulty in the case of Pears. Should grafting be decided upon, cut away the main stems at *a* the first year, in order that the vertical shoots may the sooner become strong enough for the purpose. In either case it is necessary to leave more young shoots at the first thinning than are required for permanent branches, so as to allow for some buds or grafts which may not take. At Bolton Hall, near Bedale, there is a long wall of Pear trees, all of which were cut down and grafted as just described some twelve years ago. Previous to that they seldom or never bore satisfactorily; but ever since, in favourable seasons, they have produced excellent crops of fine fruit. Some of the trees cover a space 18 or 20 yards long by 5 yards in height, and when full of fruit have a fine appearance. H. J. C.

CULTURE OF RASPBERRIES.

RASPBERRIES will thrive and bear fruit in almost any kind of soil that is well manured; but the finest fruit is produced by plants growing in a deep rich loam. Raspberries produce a thick mass of fibres near the surface, and therefore are very susceptible of drought, which causes the fruit to come small and shrivelled. They will, however, root deeply if encouraged to do so. Before a new plantation is made, the ground should be trenched two good spits deep, or, what is better, 2½ ft.; but this must in some measure depend on the character of the sub-soil, as, if it be of an inferior quality, it will not be advisable to bring much of it to the surface. It must, however, be loosened up at the bottom of the trench. In the process of trenching, plenty of manure or garden refuse

should be worked into the ground, so as to provide sufficient food for the young plants. The best time for planting is as soon as the canes have shed their leaves; but they may be planted with success at any time from October to the end of February, and the most suitable for the purpose are such as come from a healthy stock of moderate growth, and which can be easily pulled up without the assistance of the spade. If they have to be dug up, unless it is done with care, they often lose great quantities of roots. The mode of planting must, in some measure, be regulated by the form in which they are intended to be trained. Where stakes are available, the simplest plan is to tie the bearing canes to them, taking care that they are securely fixed in the soil. The stakes should stand out of the soil about $4\frac{1}{2}$ ft., and to each of them should be tied, when the plants have become established, five or six of the strongest and best-placed canes from each stool, after the fruiting canes of the previous season have been removed. Assuming that this plan of training is adopted, they should be planted in lines not less than 5 ft. apart, and the distance asunder in the line should be the same, or not less than 4 ft. They will not throw up very strong canes the first year, but if the fruit be sacrificed, and the canes cut to within 1 ft. of the ground, they will throw up much stronger canes the following season. Another mode of training is called the hedge system. It consists in placing strong posts at each end of the row, and connecting them with galvanised wires strained through intervening iron standards. Thus a trellis is formed on which the canes are trained, and, if properly fixed, a plantation of Raspberries thus treated will last for years. Where this system is adopted, the canes should be planted about a foot apart, and the shoots should be trained a little diagonally. Some growers dispense wholly with supports; they merely place the canes in bundles, and unite the tops from each pair of stools, thus forming a series of arches on which the fruit is borne; this is, however, a plan which cannot be recommended. Some good early fruit may be obtained by planting the canes at the foot of a south wall, and training them in the form of a fan. After planting, surface-dress with decayed manure, which will exclude frost, and the rains will wash its nutritive properties to the roots. During the summer time the ground must be kept clear of weeds, and the soil occasionally loosened with the Dutch hoe. When the plants have become established, and the young canes in the growing season have made about a foot of new wood, all useless suckers should be pulled away in order to admit light and air to such canes as are selected to remain. When the fruit is gathered, the canes that have borne it should be at once cut out, so as to give increased space to those intended to bear next year's crop, and as soon as the leaves have fallen, the latter should be thinned and regulated. This cutting out of dead canes and thinning those that remain, may be done at any time before the beginning of March, but, as regards neatness and utility, it cannot be done too early. After regulating the canes, some recommend the ground to be dug and a quantity of manure to be worked in about the roots, but it is questionable whether such practice is not a mistake. A better plan is to loosen the soddened surface with a steel fork, and then to mulch with 2 or 3 in. of decayed manure, which will protect the surface roots from frost in winter and drought in summer. Of varieties, the best are *Barnet*, or large red; *Carter's Prolific*, *Red Antwerp*, *Yellow Antwerp*, and *Fastolf*. The *Barnet* produces very large fruit, of a purplish-red colour. It is larger than the *Red Antwerp*, but not equal to it in flavour; it is, however, an excellent variety, and a very abundant bearer. *Carter's Prolific* is an excellent kind, which bears large, finely-flavoured fruit. The *Red* and *Yellow Antwerp* are both so well known that they require no comment. The yellow variety will occasionally bear fruit in autumn. The *Fastolf* has of late years somewhat superseded the preceding varieties. It is a great bearer, and though it is a summer Raspberry, it has the desirable property of occasionally bearing fruit in the autumn superior even to that of the reputed double-bearing kinds. Several new sorts have lately been introduced, such as *Prince of Wales*, *Semper Fidelis*, and *Belle de Fontenay*, but of these I have had no experience. They are said to be improvements on the preceding, and the last named is a fine autumn-bearing variety. *Autumn Black* is perhaps more singular than useful, and is evidently

the result of a cross between the Blackberry and the Raspberry. It has the rambling habit of the Bramble, with the succulency of the Raspberry and a little of the Blackberry flavour. It is said to be valuable for preserving. R.

FALLACIES IN MODERN FRUIT CULTURE.

THE common fault of critics is that they go too fast or too far. Description runs into exaggeration alike in pointing out faults in existing practice and in picturing the possibilities of improved modes of culture. The paper recently read before the Society of Arts by Mr. Shirley Hibberd affords a striking instance corroborative of the above remark. This was described by a contemporary as a full tilt against the modern methods of fruit growing. That is exactly what Mr. Hibberd did; and no one, however highly gifted, can be expected to observe very closely when running at full speed. Hence, the course of culture pursued by practical pomologists was described as having for its objects the starving of the soil, the stock, and tops of trees, and, as a necessary consequence, the prevention of fruit-bearing. This result seems to have pleased our critic much, for we find it reiterated even in stronger language, thus:—"The idea that has taken firm hold of amateurs and others is that the smaller the tree the greater will be its productiveness, and the proper development of this faith is that fruit will most abound where there are no trees at all." And, I may add, that the natural rebound from such a belief, which, we infer, may have been held by Mr. Hibberd for the last quarter of a century (during which he has been proving all the best known modes of fruit tree management), is that the sturdy Oak and the graceful Beech are the models for fruit growers to study. "Nobody above the status of a lunatic practises pruning and pinching with a view to augment the production of Acorns." But what has that to do with fruit culture? No one plants Oaks for Acorns or Beech trees for their Nuts. These are grown for timber or bark; and if Apple, Pear, Plum, and other trees were also grown for furniture makers, and not for their annual produce, we should say to the root-pruner, summer-pincher, and all those bent on a starving or restrictive regimen, let the trees have their tap-roots to dig deep and run far, and their heads to spread wide and climb high; throw not away the product of a summer's sunshine at the winter pruning; the more roots, and the finer the top, the more timber; and, just because that is so, we recommend dwarfing stocks, root-pruning, and other starving processes, to hasten and augment fertility. There is less of analogy than contrast in the manufacture of timber and the production of fruit. But our critic says no! "The Oak is a fruit tree, its Acorns have a money value;" and then, to make his analogy doubly sure, adds, "an Oak tree produces Acorns, a Beech tree Beech Nuts, an Apple tree Apples; and as no one starves the two former into fertile ways, why starve Apple, Pear, and Plum trees, the fruits of which are so much more valuable, when, by leaving them alone, they are certain to bear sooner and more abundantly, and last the longer?" And, further on, we are told man can do but little to hasten or augment fertility. Of course, if our critic seriously believes all this, he must advocate the unrestricted growth of all fruit trees, and that is virtually what he does. "Start with the ugliest trees you can find"—there may be a great deal more in this advice than is readily apparent—"select good varieties, choose the best soil, and leave the climate and Nature, assisted by a few weights on the stronger branches to allure them into fruit-bearing by make-believe crops, to do all the rest." Well, no doubt, for the culture of fruits in orchards, the plan of free and natural growth has its merits; and had Mr. Shirley Hibberd advocated it for that purpose, without caricaturing the most interesting, successful, and profitable methods of restrictive fruit culture in gardens, his paper would not have evoked the adverse criticisms passed upon it. But not only has our critic run wild in his analogies, but gone far astray in his statement of facts. Instead of doing little to hasten or augment production, the modern pomologist urges fertility on, and keeps it almost abreast of growth. Trees bearing fruit within a year of being grafted are now by no means uncommon, and fairly good crops are gathered within two or three years. The fact is, modern pomologists have attempted a match against time and space, and they have mastered both, by growing far more fruit of higher quality in less time, within less space, than was ever done or dreamt of under the old-fashioned system of fruit growing, to which Mr. Hibberd would have us hie back. No! we have seen the beauty and productiveness of restrictive training, and, as far as the garden is concerned, we mean to abide by it, as regards pyramids, bushes, and cordons of all sorts. But then we do not amputate the roots to starve our trees, and, where they show a little vigour, stop them again to throw them back into their former state of starvation. On the contrary, we root-prune our

trees, perhaps once or twice in twenty years, to multiply the number and improve the quality of their roots, so that they may be able to provide the trees with better nutriment. The result is no fishing-rods to waste a summer's sunshine, whether cut away or allured years after into fruit-bearing by pulley-pruning (an expedient by no means novel), but wood of moderate strength, bristling with flower-buds. The starving stock also has its important mission in hastening and augmenting production. As Mr. Tillery so well points out (see p. 182), the roots of such stocks are different, and keep nearer the surface, not to starve, however, but to supply the tree with more fertile food. These stocks have proved the greatest boon to the modern pomologist; they enable him to gather more fruit, and of better quality, within the compass of a few yards of a mere line of cordons than were often found on the great orchard trees of bygone times, to which we are now urged to return. As to top-pinning, no doubt a few zealots may have carried it to excess. Mr. Hibberd may, however, be surprised when we inform him that we have Apple cordons four years old on the true Doucin stock that have neither been pruned nor pinched. Each year the fruit hangs like ropes of Onions, and if that does not perpetuate fertility, then assuredly pulley-pruning is a fallacy and a delusion. As to other trees, a single stopping in June is generally all they require, and we have yet to discover that the practice starves the trees. We know, on the contrary, that it diverts vital force into fruitfulness—an object which is highly valued by most fruit-growers. Mr. Hibberd will hardly realize, perhaps, that modern fruit culture is almost the opposite of what he has represented it to be. It may be defined as a means of obtaining the most fruit with the least interference, and without any loss of time, vital force, or space. There is less hacking of branches, less root-chopping than formerly. Fertility, once established, reproduces and perpetuates itself; and as "nothing succeeds like success," so the surest recipe for continuous fertility is an annual crop. When trees are once moulded into such habits—and root-pruning and dwarfing stocks, and even top-pinning, may have much to do in this moulding—a masonry inactivity is the highest art of the cultivator. His business is not to starve but to fortify the trees, and lighten their load of fruit so as to adapt the weight of the crop to their ability to support it. Thus, instead of a system of chopping and starving, as represented by our critic, fruit culture is a wise means of nurturing and feeding fruit trees with skill so that the greater portion of the growing power shall be expended in promoting their necessary healthy development, and in the production of the best quality of fruit on the most limited area. Keeping the above in view, and abundantly feeding small fruit trees with liquid and solid top-dressings when required, they far exceed tall orchard trees in beauty and productivity.

D. T. PISH.

Mr. Shirley Hibberd's plan of tying stones to the branches of fruit trees is essentially that of a non-practical man. He asserts that he adopted it many years ago, but that he has kept the secret till now. It would be interesting to know how far he has really tried his hand at the practice, and with what actual results. The figure of a Pear tree trained in this way, which lately appeared in the pages of a contemporary, is incorrect, so far as the "pulleys" are concerned, for a tree similar to that represented must have required at least $\frac{1}{2}$ cwt. of bricksbats to bring it into shape. The conclusion is, therefore, irresistible that Mr. Hibberd's model tree is a mere fanciful sketch, having no foundation in fact. To test the matter practically I attached some pieces of brick to the moderately-strong shoots of an Apple tree grafted on the Paradise stock, hanging them on about the base of the last year's shoots, exactly as Mr. Hibberd has shown, and I found that they required to be above $1\frac{1}{2}$ lb. in weight to bring the branches down to nearly a horizontal position; what weight, therefore, strong shoots, such as trees on the free stock make, would require, your readers may guess. It may, I think, be safely predicted that Mr. Shirley Hibberd's notable disquisition on fruit trees will not move a single "dwarf stock" from its place anywhere; and as for the "pulley system" of pruning, it will speedily effect its own cure wherever it is tried. Since writing the above we have had a gale of wind here, and we hung the bricks on again—half-bricks are best, as being angular they do not slip out of the string, and are just about the right weight for small trees—and it is impossible to convey any idea of the clashing which they made as they swayed about in the storm, grinding the bark off the shoots, knocking off the fruit-buds, and almost threatening to rend the branches out of their sockets.

S. W.

In reference to my remarks last week (see p. 202), allow me to say that any one who reads attentively what I stated respecting fruit growing in orchard houses will see that I did not utter a word against that system, so long as the trees are of a size to bear anything com-

mensurate with the cost of production. My strictures were unmistakably directed against little trees in pots. I am aware that Mr. Grieve, Mr. Tillery, Mr. Douglas, Mr. Wilson, and Mr. Pearson all grow fruit trees in pots, and with the best results, and I am also acquainted with others who adopt the same practice, and carry it out with equal success; but all this does not stamp the practice as sound, or, in other words, that as great a quantity of good fruit can be grown by it at the same expenditure of labour and material as with larger trees. I merely alluded to the pot culture of little fruit trees as the opposite extreme to Mr. Hibberd's exclusive advocacy of unrestricted growth; and, like all other extremes, I maintain that both are mistakes. I have so much faith in conclusions based upon actual experience, and so little in such as are arrived at without it, that I make it a point never to offer an opinion upon anything connected with gardening matters that I have not tested. Like others, a number of years ago I practised the little-pot culture of Peaches, Nectarines, Plums, and Cherries; the fruit produced was of good quality, and as abundant as the size of the trees would permit, but the labour was just double that which is incurred when the trees are planted out, and the weight of fruit was less. My trees very soon got into pots above the orthodox size; I was then so far satisfied with the results that I have not seen anything in their way better, but they in no way equalled trees that were planted out, so far as the production of the maximum of fruit with a minimum of labour was concerned. Despite all that has ever been advanced by the most determined advocates of this method of fruit culture, it is something like taking a circuitous route to get at a given object instead of walking straight to it. The only advantage I ever could find in it was in being able to slightly prolong the Peach season by retarding the trees in spring, which the ability to move them out of the sun's influence afforded.

T. BAINES.

WARTS ON VINE LEAVES.

DURING the early spring months warts often form a serious impediment to the growth of many Vines. They are generally most abundant on young Vines—older ones have more power to resist their attacks—but all are, more or less, subject to them. When very plentiful their effects are visible throughout the whole season. Vines pushed into growth in January, February, and March are more liable to be attacked than those started later in the season. The undersides of the leaves become covered with small rough protuberances, about the same colour as that of the leaf, but sometimes paler. They vary in size, but are usually not larger than a pin's head. In some cases there are only one or two on a leaf, while on others they abound to such an extent that the leaf ceases to expand, curls up, and assumes an unhealthy appearance somewhat like that of leaves covered with green fly. Some leaves grow to a considerable size before the warts appear, and, where this is the case, the latter do not check the growth to the same extent as when the leaves are affected before they are half developed, and when this happens, no after care or treatment will remove the excrescences. A high temperature, and a close, stagnant, excessively moist atmosphere favour their growth to a great extent, and these are conditions common in spring in many structures in which Vines are grown. The amount of moisture should be in proportion to that of the heat—an important matter, the non-observance of which, especially during damp, dull weather, when the ventilators cannot be opened to any great extent to admit a free circulation of air, is almost sure to induce warts. If moisture were cautiously dealt with at such a time, fewer evils would be the result.

J. MUIR.

FORCING PEACHES AND NECTARINES.

THERE are certain facts connected with forcing that cannot be too much impressed upon those who have to do with the practice, and among the most important are those relating to temperature. For example, there is perhaps no more fertile course of failure in the forcing of a great number of fruits and flowers than too high a temperature at certain stages of growth. Let us take the Peach and Nectarine. Every cultivator knows that well-ripened wood and fruit-buds are essential to success; yet all may be ruined at the outset. Let any one introduce a healthy, well-matured Peach tree, in a pot, into a pine stove, or vinery temperature, and no matter how forward the buds may be, or how plump and well-matured, leaves only will be produced, and few or none of the flowers will ever expand at all. We have tried such an experiment, and have often noticed the effect of such treatment in other cases. In some of our Peach houses the lower branches of the trees are unavoidably very near the hot-water pipes, and these branches would push annually into leaf without flowering, were the leaf-

buds not pinched close back as fast as they grew till the flowers are expanded. Ill-ripened shoots are most liable to push into leaf first, but in all cases it will be found a safe and excellent plan to pinch the leaf-buds as soon as they can be laid hold of by the finger-nails. Under healthy conditions the Peach is always in flower before the leaves are out; when both push contemporaneously it is a bad sign, but one which is seldom seen except indoors, and under artificial treatment. In forcing the Peach during the earlier stages, the most favourable conditions are bright sunny days, no matter how frosty. At such times the temperature may be run up with perfect safety to 85° with air, even when the trees are just in flower, provided the temperature drops at night to a low figure, say 40° or even 35°, and the bad practice of steaming the houses at night is avoided. It is the dull weather which tries the skill of the practitioner; then the temperature must, under all circumstances, be run up by fire-heat to 55° or 60°, at least, during the day; and it should not fall below 50° at night, if for no other reason than that of getting up heat early in the morning with the light. No moisture should be given except bedewing the flowers about every other day and early in the afternoon with the syringe, to facilitate the setting process; but continual saturation must be shunned. This year our early trees hardly experienced one blink of sunshine during the whole time they were in flower, a leaden snowy sky prevailing all the while; but under the above treatment both Peaches and Nectarines have set their fruit in clusters. J. S.

The French Paradise Stock.—Mr. Baines cautions us against using this stock indiscriminately upon all soils. I have never observed that any one recommended it as fitted for such work, but, on the contrary, it has been frequently said of late years that it is most suited for strong and wet soils, where the Crab stock is most objectionable. The fact that Mr. Baines saw the French Paradise cultivated forty-five years ago does not make it the less true that this peculiarly distinct stock was condemned by our leading pomologists as tender and useless except for dry soils, &c.; but an acquaintance commenced so long ago ought to have saved Mr. Baines from confounding the Paradise with the Doucin stock, as he does (see p. 203). These stocks are quite distinct both in character and in their effect on the varieties grafted on them.—W. T.

d'Arcy Spice Pippin.—This excellent Apple, when ripe, has a yellowish green skin, almost obscured by brownish russet, especially on the sunny side, where it is also tinted with deep shining orange scarlet, the whole thinly strewn with dark russety dots. Its flesh is rich, crisp, juicy, and aromatic, with a honied sweetness and delicious aroma. Some one called it Spring Ribston, and Mr. Harris, of Little Baddow, near Chelmsford, re-named it Baddow Pippin. Mr. Harris, however, ought to have known its true name, as it has been cultivated about Tالشهد d'Arcy above one hundred years. Dealers from Chelmsford used to go annually to d'Arcy for this Apple, which was much prized, and met with a ready sale. When I first saw the fruit of this Apple I believed it to be that of Reineette du Canada, which it much resembles in shape and colour; but on comparing the trees I found that they were quite different.—JOHN SCOTT, Merrittott, Creukerne.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Beurre Sterckmans Pear.—This Pear, which, at this late season, is good in all respects, is not so well known as it deserves to be. It is of medium size, with a dullish-red skin, and a melting, sugary, rich flesh. The tree is a profuse bearer on either the Quince or Pear stocks.—W. H.

The Earliest Figs.—Intending to pursue Fig culture on a somewhat extensive scale, I shall be greatly obliged by any of your correspondents telling me which are the best among the early kinds, particularly among the new and fine kinds of which we have heard so much.—K. S.

Fruit Prospects for 1876.—The prospects of a good fruit crop are at present very satisfactory, the trees being full of flower-buds. Equally important, too, is the fact that we may now expect a somewhat late season of flowering, which, in our fickle climate, is a circumstance much to be desired.—J. G.

The Best White Grapes.—To Mr. Newton's interesting list of White Grapes (see p. 183), allow me to add the Trebbiano, a kind with which I am so delighted that two years ago I planted a house with it. Our great month for Grapes here is January, and Trebbiano does really good service at that time. It is not a Muscat in flavour, nor a Gros Colman in size, but, when grown in heat, its colour is fine, and the flavour refreshing.—R. GILBERT, Burghley.

Best Vines for an Unheated Orchard-house.—The Esperione and the Royal Muscadine are two excellent varieties for a cold house, and two which are easily managed. They will ripen under glass without heat during any season, and so much can hardly be said of any other variety, except perhaps the Black Cluster, which is hardly worth a place under glass. The Esperione, when well grown, is little inferior to the Black Hamburgh, which will sometimes, but not always, ripen well in an unheated orchard-house.—P. G.

THE INDOOR GARDEN.

CULTURE OF APHELANDRAS.

APHELANDRA CRISTATA, when well managed, is still one of the most beautiful autumn ornaments of the warm conservatory which we possess. It succeeds in either peat or loam; in the former its leaves grow to a larger size and assume a deeper shade of green than they do in loam which produces shorter growth, and generally flowers a little deeper in colour. After trying the plant in peat and also in loam, as well as in a mixture of equal parts of each, I have found that the latter is preferable used in equal proportions; both should contain a fair amount of fibre and have added to them one-seventh of sand. Cuttings strike readily when taken off with a heel, and placed singly in 60-sized pots in a mixture of half-sifted peat and sand, with a little clean sand on the top; give a little water when they are inserted, and at once put them under a propagating glass in a temperature of 70°. They should be put in as early in the season as they can be had in proper condition, which will be when the young growths are about 3 or 4 in. in length. This they will have attained by the middle of April, provided the plants from which they are taken have been kept in a warm house through the winter. Keep them sufficiently close to prevent their flagging, but not so as to cause the leaves to damp—a condition from which they are likely to suffer if a little air be not given. By the end of May enough roots will be formed to admit of the propagating glass being dispensed with. They should then be moved into 6-inch pots. For this first shift the soil should be sifted and used, as already advised, in equal proportions of loam and peat. They will grow quicker if a sixth part be added, consisting of half leaf-mould and rotten manure, with as much sand mixed with the whole as will keep it porous. Pot moderately firm, and place the plants on a front shelf, where they will get plenty of light, in a house or pit, with a night temperature of 75°, allowing it to rise 10° higher with air during the day. Shade in the middle of the day in sunny weather, and give enough water to keep the soil moderately moist. Pinch out the points of the shoots as soon as growth has fairly commenced. This *Aphelandra*, being of a somewhat erect habit of growth, is disposed to run up without branching out, unless stopping the shoots is attended to. Syringe overhead in the afternoons, and close the house while the sun is upon the glass; by the middle of July the young plants will have made sufficient progress to bear moving into pots 2 in. larger, now using the soil in a more lumpy state, but in similar proportions as before. Again pinch out the points of the shoots, and treat as hitherto in respect to heat, shade, and moisture, both at the roots and by syringing overhead, keeping the atmosphere all through the growing season moderately moist. About the end of August discontinue the use of the syringe, and give more air, and as the weather gets cooler reduce the temperature 5°. They will now begin to throw up flowers, and should be set in the lightest place which the house affords. When the bloom-spikes are half open, the plants, if required, may be placed in a conservatory kept at an intermediate temperature. Should it not be warmer than an ordinary greenhouse, they must be allowed to remain in the stove, as they would not stand keeping too cold during the autumn. If whilst in bloom they are subjected to a somewhat lower temperature than that in which they opened, no more water must be given than will keep the leaves and flowers from flagging, or the roots will be apt to suffer. As soon as the blooms have decayed, the shoots should be cut back to within a couple of joints of where they were shortened at the second stopping in the summer. Keep the plants through the winter in a temperature of 60° in the night and a few degrees warmer in the day; give no more water than is necessary to keep them growing slowly. As the days lengthen give 5° more warmth by day and night. By the end of March the roots will begin to move; they should then be turned out of the pots, and as much of the surface-soil as is not occupied by them ought to be removed. Give a three or four inch shift according to the quantity of roots they have got, using the soil in a little rougher state than when the plants were smaller.

When the potting is completed replace them in the stove, treating them generally as in the preceding summer, except that they will only require stopping once, unless it is deemed advisable to have some in flower late in the autumn. About the beginning of May pinch out the points and tie the shoots out in an horizontal position, so as to induce a bushy form. This will also cause some of the lower eyes to break and produce more flowering growths. The plants require very little support, but a few neat sticks should be used to keep the shoots in their places. Treat them through the summer as during the first season. If only stopped once they will flower considerably earlier than they otherwise would do; when the bloom is over, again shorten back the whole of the shoots to a couple of eyes beyond the point to which they were cut back the autumn before; treat them similarly through the winter. In the spring again turn them out of the pots, and remove as much of the old soil as can be done without unduly disturbing the roots; re-pot in 2 or 3 in. larger size, which, unless very large specimens are required, will be found big enough to grow the plants in for a number of years, provided a portion of the old soil is replaced by new as hitherto in the spring, in addition to a liberal use of manure-water through the growing season. Thus managed, Aphelandras will last in good condition for years.

T. BAINES.

POT BOUQUETS.

The culture of plants in pots for room decoration has greatly increased within the last few years, and very large sums are annually

A Pot Bouquet.

expended in Covent Garden alone for the pretty little plants in pots now so often seen in the window casements and apartments of town mansions. Our illustration shows quite a bouquet-like arrangement, consisting of crimson Tulips and Lilies-of-the-Valley, neatly fringed with Maidenhair Fern, an arrangement, we believe, first adopted by Mr. Herbst, of Richmond. Potfuls of Snowdrops may also be seen tastefully fringed with Fern and blue Scillas. Many other spring-flowering bulbs might likewise be associated with Ferns or other handsome-leaved plants with advantage. Sometimes mixtures of bulbs are planted in zinc trays, or rather pans, which are set in shallow wicker baskets and covered with Moss, through which the bulbs grow, and, when in flower, have a handsome appearance.

B.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

The Coconut in Florida.—The culture of Coconuts is to become an industry in Florida. The climate is adapted to them, and it is thought their culture will be profitable. The trees can be planted about the distance apart that Apple trees are usually set, and they are much longer lived than Apple trees.

Wintering Alternantheras.—We find no difficulty in wintering old plants of these after lifting them. We put them into pots that will just hold their roots, using free, porous soil, and place them on a dry dry shelf in a house where the temperature is never below 55°. Too much moisture must not be maintained during the short days. We have a lot now, which will soon be broken up, and every plant will give us, at least, seven good plants, besides a crop of cuttings soon.—A. H., *Therapsy*.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Indoor Plants.—Mignonette that is flowering in pots should be regularly supplied with manure-water; when this is given continuously from the time the plants show bloom, not only will they continue to flower much longer, but the leaves will have that dark green healthy hue that indicates liberal treatment; whereas, when Mignonette is grown without sufficient sustenance, it assumes a sickly yellow appearance. Herbaceous Calceolarias should also be well fed with manure-water, and if the latest-sown plants be not already in their blooming pots, they should be put in them at once, as, if this be deferred until the roots get stunted, they will be little benefited by subsequent shifting. Cinerarias should have liquid manure alternately with water; indeed, if not given too strong, they will be none the worse for manure-water only. Pelargoniums will now require more water; keep them well tied out, near the glass, and do not overcrowd the plants; it is better to grow a score with abundance of room than double the number with insufficient space, as the former will not only be much more satisfactory in appearance, but will produce more flowers. Cyclamens, now flowering, must be kept well up to the light, otherwise their bloom-stems become weak and liable to damp.

Pits and Frames.—As soon as the heat has sufficiently subsided in Cucumber beds, which will be (according to their size) in a fortnight or a few days more from the time they are made, the soil should be put on. It is often safer for amateurs to test the heat with a thermometer than to trust to the more recognized method of being guided by the customary stick being inserted in the middle of the bed, as without some experience they are liable to err in either putting in the soil before the heat has got sufficiently low, or deferring it until the heat is too much reduced. There are instruments made expressly for the purpose of showing the temperature of beds composed of either tan or other fermenting materials, but such not being at hand, an ordinary thermometer will answer the purpose, plunging it well down in the centre, which will be the warmest place. As soon as the temperature has fallen to 80°, the soil may be put in; but where the bed is large, especially in depth, sometimes the heat will again rise to such an extent as to injure the young plants, which will quickly make their appearance after the seeds are put in. The soil should be laid evenly over the surface of the bed to a depth of 6 in.; if less, the rank steam from the manure will sometimes destroy the plants. Sow the seeds singly in small pots half-filled with fine soil, mixed with a little decomposed manure or leaf-mould with some fibrous material in the bottom, which will be sufficient drainage, and need not be disturbed when the plants are potted on; cover the seeds with $\frac{1}{2}$ in. of soil, and plunge the pots; in six or eight days the seeds will germinate, and when they are 3 in. above the soil, fill up the pots with earth, into which they will emit roots all up the stem, which will much strengthen the plants. Cuttings of Fuchsias, bedding plants, &c., that will root in heat may also be struck in the same bed, but with all subjects of this description it is necessary to be very careful that they are free from aphides or any other insect, as, if there be any trace of these pests, the warmth will speedily bring them into active life, in which case they will fasten on the Cucumbers, from which, on account of their tender nature at this early season, they are very difficult to eradicate without great risk of injury to the plants. Where cuttings are put in a Cucumber-frame I should advise always the precautionary measure being taken of dipping them in tobacco-water before they are put in, whether there are any insects perceptible or not. At first, whilst the bed is very warm, it will most likely be necessary to leave the lights tilted about an eighth of an inch at the back during the night, securing a mat down over it; the lights should be covered with double mats, fastening them well down over the sides; it will also be advisable to put some litter, a foot or so in thickness, all round the sides of the bed, bringing it well up the sides of the frame, or, if this be not obtainable, thin boards nailed together in the form of shutters will assist in preserving the heat much longer. Beds that have been made up for Potatoes should have 9 in. of soil put on them at once and the Potatoes dibbled in, covering them about 4 in.; when several inches in height add a little more soil. Potatoes that have been prepared as advised some weeks ago by placing them thinly to sprout will now be fit for beds of this description; put them in rows 14 in. apart, and 9 in. or 10 in. between each plant in the rows. A thin row of Radish seed may be sown betwixt each row of Potatoes, which will come in so as to be used before the Potatoes require the remaining soil to be added. Care must be taken that the Potatoes are not planted whilst there is too much heat in the bed, or they will be destroyed, or so injured as to be unfit for use. 60° of heat in the soil is quite enough. Similar beds intended for Carrots should have 9 in. or 10 in. of earth put in. This ought to be of a moderately-fine description,

such as has been used for Cucumbers or Melons the year preceding. Sow the Carrots at once in rows 8 in. apart. Dahlia roots for producing cuttings should now be started in beds similar in strength to those for Potatoes, or, where the frame room is limited, a corner of the Potato frame may be apportioned to the Dahlias, which will do much better than when subjected to greater heat; as, when the roots are too warm, they throw up shoots soft and weak that do not make such vigorous plants as when grown slower.

Roses.—As regards the best time to prune Roses there are several things to be considered; in low, damp situations where spring frosts are much more severe than upon high and dry ground, it is a mistake to prune so early as to endanger the first shoots, as, when this happens, the second efforts which the plants make are always weak, and result in a poor display of flowers; neither is it well for those who have only a few Roses to run any risk by early pruning. Those who have a considerable number will do well to prune a portion at different times—say, some at the beginning of March, another portion ten days later, and another at a similar interval; not only are the chances of fine flowers increased by this, but there will be a longer succession of bloom. It is not advisable for amateurs who grow Roses in great quantities to prune so closely as those who require only a few fine flowers for showing; at the same time it is well to cut out all weak shoots, as nothing is gained by allowing the plants to become crowded.

Potatoes.—To succeed the hot-bed grown Potatoes, or, where the means of growing them in a hot-bed do not exist, they may be planted in a cold frame; this can be either an ordinary garden frame, or a light one made of boards, or, where fibrous material is plentiful, a turf-pit may be made at little cost, cutting the turf in strips 1 ft. wide and 3 or 4 in. thick, forming the sides and ends of the pit similarly as with bricks; lay the Grassy side downwards to a depth of 15 in. at the back and 10 in. in front, surmounting all with boards nearly the width of the turf walls and 1 in. in thickness, nailed together at the corners, with cross-strips of board 6 in. wide to carry the lights or shutters; if straw or ordinary best matts be used, the strips will require to be slighter and more numerous. A turf-pit of this description may be turned to many purposes after the Potatoes are cleared out. These cold frames or pits should occupy a sunny situation, and if the ground does not naturally slope to the south it should be made to do so, so that they may get all the sun possible. The southern side of a wall should have a row of early Potatoes planted at about 6 in. distance from it; when aboveground, they can be easily protected with a light board reared in front of them when there is danger of frost, and will, so managed, be fit for use a fortnight or three weeks before those in the open ground. Should the land be very wet, it is better, even if the time have arrived for sowing or planting, to delay slightly than to tread the ground when in such a state, as it never works kindly, and seeds sown in too moist a soil rarely do well. Except in very dry situations it will be necessary to keep this in view during the present spring, owing to the more than average rainfall of the past autumn and winter.

Seakale.—As soon as the soil is sufficiently dry, Seakale should be planted, as, upon getting it in early so as to give it a long season of growth, depends in a great measure the size and strength it will attain before autumn. The whipthong-like roots advised to be saved when taking up last year's plants for forcing are the best to start with. The stronger the pieces that are used for planting the better usually the crowns will be that are grown from them. If sufficient pieces can be obtained as thick as one's finger, and from 6 to 9 in. long, they are to be preferred to smaller pieces, but where there is a deficiency of these large roots, some of a smaller size will answer. If the ground has been prepared as advised a short time ago, the holes may now be made with a dibble, just leaving the top of the piece level with the surface of the soil, filling the holes up as the roots are put in. Plant them 15 in. apart every way; where there is no stint of ground 18 in. will be preferable. Should these roots not be obtainable, pieces of the crowns that have been forced may be planted, but they are not so good as the roots. When this crop has to be grown from seed, the ground, if not already prepared, should be at once got ready by manuring and digging, as it ought to be sown during this month. Where there is a superabundance of this vegetable, cover the crowns at once with 8 or 10 in. of old tan, sand, or fine ashes, and they will produce excellent Kale, cutting it for use before it has grown through the covering material; a slight washing will leave it as clean and white as possible.

Rhubarb and Celery should now be planted; Rhubarb in a piece of very rich ground. If the land be of such a nature as to admit of its being trenched 3 ft. deep, putting 3 in. of well decayed manure in the bottom, and not stinting the upper portion, the beds will last for years, mulching annually; with the

ground thus well prepared, not more than half the space need be occupied to produce a given quantity as when the land is poor and insufficiently manured. Celery should at once be sown in pans, covering the seeds with a fourth of an inch of soil, and placing them in either a hot-bed that is at work, or in a house where there is heat; if not, in a cold frame, but, in the latter case, it will not be ready for use so early.

Greenhouse Plants.

Keep Cactuses, Echeverias, Kalosanthes, and plants of that class on light shelves well up to the glass. Any of the latter that are leggy, or not likely to bloom satisfactorily, should at once be cut down, leaving about 3 in. of the young stem to break again. The strongest shoots, if formed into cuttings and inserted in sandy soil, will soon strike root, and make useful little flowering plants in small-sized pots. Where there are surplus plants to admit of a few being treated as above at this early season, the foundation is laid for forming good specimens to come in next year. It is almost necessary to treat a portion of the stock in this way, as the plants do not form growth in time to flower if they are not cut back till July. Such as were pruned in at that time last year, and are now too crowded with young shoots, should have the weakest thinned out, and the others thinned and regulated if found to require support.

Chrysanthemums.—Cuttings of these put in now will develop themselves sufficiently for ordinary purposes if liberally treated, without which they will scarcely deserve house-room when the flowering period arrives. These strike best in cold frames, where they can be kept close and moist, or, if placed in heat, it should only be very slight. Those already struck should be potted and placed in a close pit or frame to give them a start, after which they must be shifted on as soon as the roots reach the sides of the pots they are in, so that they may be kept growing freely without check till they are placed in the pots in which they are intended to bloom. The soil can scarcely be too rich for them, as they are very gross feeders, but the manure added should not be of a rank nature. Cow manure, that has been laid up in a dry place for a year or so, is the best for this purpose; but, failing this, such as can be obtained from old hot-beds, if in a thoroughly decomposed state, may be used in its place.

Cyclamens.—The easy way in which these may be raised from seed, and the rapidity with which they may be grown to a flowering size, together with the effect they produce at a dull season of the year, place Cyclamens in the front rank of winter decorative plants. To get bulbs for next season that will bloom, seed can scarcely be sown too soon. A light vegetable soil, such as peat or leaf-mould, is best suited for their growth. As the seeds are large, they should be covered with half an inch of sandy soil; and to assist them to germinate quickly, they should be placed in a strong moist heat, and, when up, be pushed forward till the time arrives for hardening them off to plant out in prepared beds in the open air.

Hard-wooded Plants.—As early-flowering Heaths go out of bloom they should be removed to a position where they can be kept somewhat close and moist, and be syringed overhead, so as to assist them to break and make free growth. Keep the balls only just moist, for which little beyond the syringing will be necessary, as with a reduced top, and no growth till they start again, very little water will be taken up for some time to come. As Epacris fade, cut away the old flowering wood to within a couple of inches of its origin, and treat the plants in every way as above advised for Heaths. Azaleas may be forwarded by keeping the house closed, and the plants damped overhead by an occasional syringing. Where any of these are out of health through having been confined to the same sized pots, or from improper watering that has rendered the soil sour and destroyed the young feeding roots, they should be looked to at once. In the latter case, the old ball should be considerably reduced by picking it away with a sharp-pointed tool, or by cutting as much as possible off with a sharp knife without injuring the large main roots. In most cases the ball may be decreased sufficiently for the plant to be potted in the same sized pot as the one it had been previously growing in, when by giving it some thoroughly good fresh fibry peat with the proper proportion of sand, followed by judicious watering, any sickly plant may be easily got into health again. It sometimes occurs that Azaleas, and plants of that class, have to be confined to certain sized pots for some special purpose, and, after being pinched, get out of condition. An inch or so sliced off equally round the ball, to be replaced with good fresh peat, will soon add to their strength and vigour. In cases where it is thought desirable to treat plants in this way, it should be set about at once, so as to afford them time to make fresh fibres before any young growth takes place. If the operation be deferred till then, the check would be too great for the young tender shoots, which would, in all probability flag and suffer injury. After re-potting as above, place

the plants in a house that can be kept close and warm without the aid of fire-heat. Syringe frequently but lightly overhead, so as not to wet the new soil, which must only be kept just moist until the roots get a good hold of it.

Pelargoniums of both fancy and show varieties will now require careful watching to keep them free from green fly, which at this season increase at a rapid rate and soon cripple the plants. To dislodge them, burn tobacco paper on a wet evening, when little or no wind is stirring, and the laps of the glass are filled up by the rain, as then the smoke cannot effect its escape, and much less suffices for their destruction. Repeat the fumigation early the following morning to prevent stragglers from recovering. If the house can remain closed for the day, the fumigation will be much more effectual, as fresh air revives any of the aphids not actually killed. Pot on young healthy-growing plants that were struck last season as soon as the roots reach the sides of the pots they are in, using for the purpose good stiff fibry yellow loam, and pressing the same well into the pots. Older plants intended to bloom early should be got into their flowering pots at once, using the same kind of soil, which should be made as firm as possible. Regulate and tie out the shoots as they require it, so as to admit light and air to the under leaves, for when these are defective, the beauty of the plants is materially affected. Keep them well up to the light in a sunny position, and close early in the afternoons of warm bright days, giving the plants a syringing at the same time, which will greatly assist their growth. The fancy kinds will stand and enjoy 10° or 15° more heat than the large show varieties, and may therefore be placed in the warmest positions or in separate houses.

Herbaceous Calceolarias and Cinerarias.—These rank among the most attractive of greenhouse plants. Pot the Calceolarias in soil, consisting of about two parts fibry loam to one of spent hot-bed manure or leaf-soil. Keep the atmosphere of the house or pit in which they are growing as moist as possible, with a night temperature of from 45° to 60°. Never allow them to become pot-bound till they are placed in the sizes required for blooming. Watch for the appearance of green fly, and smoke the plants very cautiously, as they are easily injured, especially if the leaves be at all damp. The shrubby varieties, such as *Sultan* and *aurea floribunda*, are likewise valuable for pots, and may be grown and treated much in the same way as the herbaceous varieties. Cinerarias that have filled their pots with roots, and are now beginning to show flower, should be assisted with liberal supplies of manure-water; if well furnished with good healthy foliage, and in moderate-sized pots, they can scarcely be overdone, unless it is given to them too strong. A table-spoonful of guano is quite sufficient for four gallons of water, at which strength it may be applied to these and most other soft-wooded plants after they have satisfactorily filled their pots. Pot on those for late blooming, using a light, rich soil for the purpose. Keep them in pits or frames on a cool, damp bottom, such as cinder ashes. Syringe well overhead, and close early in the afternoon, while the sun is on them, to promote free growth.

Fuchsias.—Old plants, to flower early, must now be pushed on in some of the forcing houses, where they can enjoy a steady moist heat congenial to their natures. Shake out and re-pot such as have broken, and stop any strong shoots of others that are in a more advanced stage, and appear to be taking the lead. Young plants must be kept growing on in a light position, where they can have the benefit of frequent syringings and a good growing heat. Stop the leading shoots when the plants have attained about the height of a foot. This will induce them to break back, and furnish themselves with branches down to the pot, so as to make well-formed pyramids, which shape is the most pleasing and suitable to show off their pendulous flowers. As soon as the top buds start again, select the best situated to train on as leaders to increase the height and size of the plants. Cuttings made from the young soft wood may still be put in to form good plants for autumn blooming, also for wintering to be grown on for early work. Fuchsias delight in a rich loose soil, such as loam, with a liberal admixture of old Mushroom refuse, or spent hot-bed manure.—J. SHEPPARD, *Woolverstone Park*.

Floral Decorations.

The accompanying list of flowers and fruits, suitable for vases, and procurable in March, gives evidence of the approach of spring. Siberian Squills, which have hitherto been obtained from pots under glass, are now to be found displaying their intensely blue flowers in the open borders. Hepaticas, too, which are not half so much grown as they deserve to be, and which keep fresh in water for a longer time than most flowers, are now favouring us with their lovely blossoms. The blue variety runs so closely into the confines of lavender colour, that it is doubtful whether it ought not to be grouped with *Heliotrope* and other flowers, under the heading of pale purple; but the bright, rosy, pink sort presents no such difficulty in colour-classification. The double varieties, being much

more dwarf, are not so useful for decorative purposes generally, though they are very suitable for "pincushion" arrangements. *Aucuba* berries are worthy of more attention than they usually receive for decoration; they are now fully ripe, and of a very rich scarlet colour; and if any objection be raised to cutting the shrubs, the berries can easily be picked, and mounted on the points of separate wires, and the wires can be grouped and twisted together so naturally in clusters, that only the closest observation would detect the arrangement. *Solanum* berries, which also grow upright, may be similarly treated; and if the wires should show, a little long Moss tied among them will effectually hide them. *Arbutus* berries, which hang down, and which would have an unnatural appearance if they were mounted in this way, do not require it, since the clusters in which they grow can be removed without injury to the tree. *Primroses* and *Polyanthus* are now opening in many shades of yellow and crimson. A few days back, Mr. Dickson, of Covent Garden, was good enough to send me some pieces of *Guelder Rose*, forced in Paris, which proved a useful addition to the list of white flowers. Time did not permit me to determine to which species of *Viburnum* it belonged; but it is probable that more than one of this genus would pay for forcing for conservatory decoration.

Blue—*Cineraria*, *Hepatica*, *Hyacinth*, and *Siberian Squill*.
Purple—*Cineraria*, *Heliotrope*, *Hyacinth*, *Tulip*, and *Violets*.
Mauve—*Cineraria*, *Heath*, *Primrose*, and *Tulip*.
Pink—*Azalea*, *Begonia*, *Bouvardia*, *Camellia*, *Carnation*, *Chinese Primrose*, *Cyclamen*, *Dielytra*, *Epiphyllum*, *Fancy Pelargonium*, *Fuchsia*, *Heath*, *Hepatica*, *Hyacinth*, *Lachenalia*, *Rose*, *Tulip*, and *Zonal Pelargonium*.
Crimson—*Bouvardia*, *Camellia*, *Cyclamen*, *Epiphyllum*, *Fuchsia*, *Hyacinth*, *Polyanthus*, *Primrose*, and *Rose*.
Scarlet—*Bouvardia*, *Carnation*, *Euphorbia*, *Salvia*, *Tropaeolum*, *Tulip*, and *Zonal Pelargonium*. Also berries of *Arbutus*, *Aucuba*, *Cotoneaster*, and *Solanum*.
Orange—*Carnation*, *Narcissus*, *Polyanthus*, *Rose*, and *Tulip*.
Yellow—*Azalea*, *Coronilla*, *Genista*, *Narcissus*, *Polyanthus*, *Primrose*, *Rose*, and *Tulip*.
White—*Andromeda*, *Arbutus*, *Arum*, *Azalea*, *Begonia*, *Bouvardia*, *Camellia*, *Carnation*, *Chinese Primrose*, *Cineraria*, *Cyclamen*, *Eucharis*, *Heath*, *Hepatica*, *Hyacinth*, *Laurustinus*, *Lilac*, *Lily of the Valley*, *Narcissus*, *Paper Narcissus*, *Portugal Laurel*, *Roman Hyacinth* (†), *Snowdrop*, *Spiraea*, *Staphylea*, *Tulip*, and *Viburnum*.

—W. T. T.

The Wild Garden.

Daffodils.—In this neighbourhood, as in many other parts of the country, the common Daffodil grows wild, generally in indifferently-drained Grass fields, where I have seen it almost covering the ground. What can be a more beautiful sight to the lover of flowers than to see the meadows a blaze of gold every spring—and why not plant them in the wild garden in equal or superior numbers? To those who would do so—and I promise them they will be well repaid for the small expense and trouble incurred—I would say, "Now is the time." Nothing is more easily done. Send round your gardener with 5s. in his pocket, and he will bring back bulbs in thousands. I am afraid to say how many I procured last spring, and for a less sum than I have mentioned. They were dug up when the bloom was past its best, and I am now looking for my reward; but, as I have just said, now is the best time, as the leaves and flower-buds are sufficiently visible for transplantation, and a whole year is saved by not waiting till the bloom is past. Daffodils seem quite indifferent as to when they are dug up, even when they are in full flower. It is, in fact, better to transplant them from their native meadows, as they only take up Grass room; cattle will not eat them, and landlocks hardly look favourably on a tenant who has quantities of Daffodils growing on his premises. Plant the fine double kinds and the varieties of the beautiful and well-known *Poet's Narcissus* (*N. poeticus*) abundantly; they will succeed in the same positions and equally well as the common Daffodil, which bulbs of the latter may fortunately be bought cheaply, a circumstance which should induce many to naturalise these beautiful plants about their uncared-for shrubby walks.

Hardy Perennials v. Weeds.—Let me ask—Why, on leaving the dressed ground and closely-shaven lawn, in ninety-nine country houses out of a hundred, should we be obliged at once (the line is too distinct) to plunge into a wilderness of such foul weeds as Nettles and Dock? Why should the ground be smothered up by such shrubs as the common Elder (unless even for firewood, and few of us care for Elder wine, and all have not sons who care for making pop-guns), when we have such a variety of hardy exotic plants and fine flowering shrubs? Most of the finest hardy perennials will thrive as well, even better, in and about the edges of thinly-planted

shrubberies. In such positions there is little fear of the harmful spade, whilst from the shelter of surrounding objects, and the depth of good decomposed leaf-soil which is sure to have accumulated for years in such places, many of the more capricious subjects will thrive more vigorously than in the dry borders. Instead of Docks and Nettles why not look upon Peonies or Irises, Phloxes or Larkspurs, and a thousand other beautiful species of hardy plants. They are as easily grown as the weeds, and the trouble consists only in once carefully placing them in suitable positions, after which they may be left to themselves; and if some of the handsomer Grasses and such Ferns as will thrive (and many will be found to do so wherever your wild garden is), are interspersed here and there, the effect of the whole will be greatly increased.—OXON.

Hardy Fruits.

Now is a good time to plant runners of Strawberries that were temporarily pricked out into nursery beds in the autumn; ground that has been cleared of Celery will be in excellent order for this purpose, if trenched, without any additional dressings, unless the land be very light, in which case give a liberal dressing of heavy loam. The soil in which the Strawberry delights is a loam of medium texture, or what may be termed neither heavy nor light. Plant out in lines at least 2 ft. apart—30 in. is not too much—and about 20 in. from plant to plant, making them firm by pressure with the hand, and mulching the whole of the ground when finished; if they have been moved with care from the nursery beds they will quickly start into growth, but no fruit should be taken from them this season, and all flowers picked off, and they will then be in perfection next year; even this year they will be of great service in places where Strawberries are forced, as by constantly keeping the flowers off, early runners are produced, and all who have to force Strawberries know how important it is, if possible, to secure early runners. All the following are good kinds, and the names are given in the order of merit:—James Veitch, British Queen, Sir Joseph Paxton, Lucas, John Powell, Keen's Seedling, Cockscumb, and Frogmore Late Pine. The best for forcing are President, Vicomtesse Hericard de Thury, La Grosse Sucra, Keen's Seedling, and Sir Charles Napier, the last named being too acid for most palates. Gooseberry and Currant cuttings may now be put in, and will strike freely in any soil or situation, if well drained. Select from the prunings the straightest pieces, not less than 1 ft. in length, and plant in lines 18 in. apart, and 5 or 6 in. apart in the row, treading them in well to ensure the soil being compressed firmly against them. As soon as the buds begin to push, pick out all of them with the exception of two or three at top, and if during the season any show through the soil, remove them also, and have single stems only to each tree. Cuttings that were put in last year should now be lifted and transplanted, giving them the necessary space, and by another season they will be sufficiently large to be planted in permanent positions. If the annual dressing for Gooseberry and Currant quarters has not yet been given, it should be applied at once, after which, sprinkle or rather scatter over the trees immediately after a shower of rain a mixture of lime and soot in a dry state, as a deterrent to birds, which oftentimes seriously endanger the crop of fruit through their fondness for the buds. All trees that are intended to be regrafted should, ere this, have been cut back for the purpose, and as soon as the sap begins to rise the operation may be performed. The scion or grafts should be heeled-in in a cool situation before the buds begin to swell, as it is desirable that the stock be in advance of the graft, hence the reason for keeping them late by cutting them early. Clay for grafting should also be got ready and frequently worked about, mixing with it cow or horse manure, which tends to make it more adhesive. All recently-planted trees, especially standards, that are likely to be injured by the wind should be securely staked, and any defective stakes that have been used for training espalier, pyramidal, or other shaped trees, and which still require such supports, should be made good at once, as there will be little time for such work a few weeks hence. Pruning ought now to be finished, and nailing, tying, and dressing the trees advanced as fast as possible; and if, through lack of time or labour, it be found impracticable to paint each tree with composition as a preventive against insects, as soon as the whole are nailed and tied syringe the walls for two or three days successively with soap-suds, which are most efficacious in the prevention of the green or black aphides. Apricots are, with us, unfolding their blossoms, and to ensure a crop, must be well protected with one or other of the materials named in a previous calendar. Here the wall trees are protected with scrim canvas worked by rollers, ropes, and pulleys, and fixed under a coping that projects 15 in.; it can be let down or drawn up in a few minutes, being called into requisition when we are visited with frosty nights, keen winds, or very bright sunshine, which last is often, through the nursing the trees have previously had, as injurious as a sharp frost.—W. WILDSMITH, *Heckfield*.

PLATE X.

THE TRANSPARENT GAGE PLUM.

Drawn by F. W. BURBIDGE.

THIS is one of the best of the Gage section of Plums, and one which, in addition to its beauty of form and colour, has the merit of being a free healthy grower, an early and great bearer, hardy, and a kind which never misses a crop. It was raised about thirty years ago, at Paris, by M. Laffay, who gave it the name of Diaphane, and it was afterwards called Reine Claude Diaphane. Some years after its appearance, M. Oberdieck, the celebrated German pomologist, described it under the name of Durchscheinende Reine Claude, otherwise Transparent Reine Claude, or, as we now call it, Transparent Gage. The fruit is a little larger and of a brighter colour, especially when well exposed to the sun, than its parent the Green Gage; it ripens from the middle of August to the end of September, and is valuable on account of its coming into use during several consecutive weeks. The annexed plate so exactly represents its general outward appearance as to render description unnecessary, but it may be stated that its flavour is only in a small degree second to that of its parent, whilst in productiveness it greatly surpasses it. The trees, too, bear fruit at a very early age, an advantage not to be overlooked. Like all Plums, the Transparent Gage should not be too much pruned; indeed, after starting the young tree fairly, the rest may as a rule be left to Nature—at least as far as pyramids and standards are concerned: the knife in unskilful hands is the worst enemy which fruit trees have.

The Green Gage, the queen of all Plums, has at least fifty synonyms, especially in France, where it is best known as Grosse Reine Claude. It was found in a wild state by M. Karl Koch in the Caucasus, and is the progenitor of a race of closely allied sorts, all excellent, but all a little inferior, as far as flavour is concerned, to the type. Taking the Gages alphabetically, we have the Autumn Gage, a beautiful pale yellow Plum, with a rich and excellent flavour; Bella, an apricot-coloured Gage, excellent for cooking; Brandy, a kind like a small Golden Drop, with a delicious and peculiar flavour, said to resemble that of brandy; Brignais White, considered by some to be superior in flavour even to the Green Gage itself; Bryanston, a larger and later kind than the Green Gage, but inferior to it in flavour; and Foote's Golden Gage, an American sort, with a rich vinous flavour. To these must be added other varieties of the Green Gage, such as Brahy's, a very large kind, resembling the Green Gage in all respects, only not quite so luscious and rich; Early Green Gage, a sort with a good deal of its progenitor in it, but earlier; Jodoigne, larger than the type and nearly as good; July, earlier than the type, and otherwise almost equal to it; Kester's, a small kind, but a great bearer, and delicious in flavour; and Late Gage, a variety which is ripe about the middle of October, both rich and good. Other Gages consist of Honrietta, an American sort, which attains great excellence in this country; Imperial, another American variety, rich and good; Moyret's, a French kind, with a pleasant perfume; Prince's Orange, coarse, and only fit for cooking; Purple Gage, a delicious little Plum, which, in a dried state, is exquisite; Keagle's, an American sort, with a good vinous flavour; Red Gage, another American kind, but not remarkable for high flavour; Shuyler's, also an American sort; Spotted Gage, coarse, and only good for cooking; Yellow Gage, called Little Reine Claude, a kind inferior to the parent in quality; Yellow Dana's, an American Gage, possessing a delicious flavour; Yellow Peters, a good sort, somewhat like Coe's Golden Drop; and Yellow Princess, a beautiful golden-fleshed kind, rich and delicious. Besides these there are, likewise, other sorts belonging to the Gage family, such as Coe's Golden Drop, sometimes called Golden Gage; the Azure Hative, or Blue Gage; Guthrie's Aunt Ann, and his Tay Bank. The Hudson, the Jefferson, Lawrence's Favourite, Lenné, General Hand, Lucombe's Nonsuch, MacLaughlin, Abricotée de Brannan, Blecker's Yellow, Denniston's Superb, and Woolston Black Gage, all belong to the Green Gage class. The Washington, too, possesses many of the qualities of the Green Gage, and, as a preserve, is the finest of all Plums.

To the foregoing list should be added Webster's Golden Gage, a kind raised about eight or nine years ago at Gordon Castle, near Pochabers, by Mr. Webster, and originally sent out by the firm of Messrs. Peter Lawson & Son, of Edinburgh. It is said to be a seedling between Coe's Golden Drop and the old Green Gage. It is a medium-sized fruit, intermediate in character between the two above-named sorts, and is highly spoken of for its hardiness in exposed situations. In the north of Scotland it ripens well, having there the flavour of a southern country Gage; it deserves to be more widely known than it is. Last, but not least, is the Lawson Gage, a Plum raised in the Carso of Gowrie by that veteran horticulturist, Mr. Archibald Gorrie, Annat Gardens. It is a hardier Plum than the old Gage, of first-class quality, and very prolific. This was also originally sent out by Messrs. Lawson.

As regards soil for this class of Plums, Miller recommends one not too wet, or heavy, or over-light and dry; most writers have followed his recommendation, which, in a general way, is not bad, but, in my opinion, not the best. Plums, like Vines, arrive at the greatest perfection in strong loamy clays, mixed with sand or pebbles. I have planted many hundreds of Plum trees in such a soil, and always with the best results. It is my opinion, too, that if all fruit trees which we bud or graft on the Plum, such as the Apricot, Peach, and Nectarine, were planted in much stronger soils than they generally are, we should not hear so much of mildew and premature decay as we do. The Moorpark Apricot, in particular, dies off piecemeal from being planted in too light soils in which there is no clay. Plum trees, like Asparagus and Seakale, like to have an occasional dressing of salt just as they are beginning to grow, but not when they are dormant. J. SCOTT.

Merriott, Creechkerne.

TREES AND SHRUBS.

DENDROPHILIA;

OR NOTES FOR PLANTERS, ESPECIALLY ON EXPOSED SEA-COASTS.
BY SALMONICRIPS.

"Be eye stickin' in a tree, Jock; it'll aye be growin' when ye're sleepin'!"—*Laird of Dumbiedyke's Advice to his Son.*

It has been said that one half of a well-spent life is devoted to acquiring facts, the other half to making use of them; but the boundary between these two periods can scarcely be clearly defined; probably in useful lives the two processes go on simultaneously. At all events, as no man can tell how long he is *fruges consumere natus*, he does well who not only uses, but imparts facts as soon as he is tolerably certain they are correct. This is especially the case regarding the planting and management of trees; for when a man lays out a woodland, the results of his labour, under equal conditions, will be enjoyed by those who live five hundred years after him (that is, if the wood be planted with a view to longevity rather than quick returns); thus, if the success attending a proper method of planting, a proper selection and management of trees be so enduring, failure resulting from ignorance of these conditions is specially mortifying. He who plants a tract of country will rarely see his trees more than thirty years old, and can never see the full results of his undertaking; but how easily he may live to see total failure attend the scheme! It is because I have seen with regret the disappointment attending well-meant efforts to adorn or to utilize our stormy coasts and hill-sides, that I have endeavoured to ascertain and put together a few facts and principles which appear to have especially conduced to the many instances of successful woodcraft in this country. Evelyn quotes a saying of Cato's: *Male agitur cum domino quem villicus docet* (It goes ill with the master whom the servant instructs). However complete the knowledge and active the habits of the woodman or forester may be, the woods, old and young, will not be made the most of if the master have to learn his lesson from the servant. It is well for that estate whose resident owner is really a woodcraftsman. It is he who must decide what land to sacrifice to planting, a sacrifice which, if rightly offered, will at no distant date be amply repaid by shelter, beauty, and timber available

for home purposes. It is he who must design all planting and management for solely ornamental and landscape effects, the woodman's duty being primarily to manage woodlands irrespectively of beauty, so that they shall be as quickly and permanently remunerative as possible. It is he who should institute, superintend, and replenish an experimental arboretum proportionate to the size of his estate, where the ornamental or commercial qualities of new and rare species may be ascertained; in short, in this, as in every other business, the master's eye will do more than the best servant, provided always, and this is not always taken into account, that the said master has a practical knowledge of his subject. A careful servant is better left alone than interfered with by an ignorant master. An instance of this kind came under my notice not long since. During a stroll with a friend through some thriving Fir woods, he remarked, "How much nicer these trees would look if one could afford to send men to trim all the dead wood off their trunks!" It is possible that had my friend been a millionaire he would have endeavoured to beautify his Fir woods by this treatment; but a slight acquaintance with the nature of resinous trees would have made him aware that injury, if not absolute destruction, would result to most coniferous trees from treatment of that kind. Fortunately for posterity, the interest which is generally taken by landowners in their woods is daily becoming more intelligent; still it must be confessed that a vast deal of money is lost by injudicious planting, and a still greater sum remains unrealised from want of care and management after planting. Dr. Johnson once said that, during the whole of his tour in Scotland he only saw two trees which were tall enough to serve for hanging a man.* It might surprise the learned doctor were it possible for him to learn that at present the county which possesses the largest acreage of woodland in Great Britain is a Scotch one, namely, Inverness-shire. The following is an extract from the agricultural returns of Great Britain, 1874, showing the relative proportions of wood in different parts of the kingdom:

	Average under wood.	Total acreage.	Approximate proportion of wood to acres.
Great Britain	2,187,078	58,815,333	1 in 27 acres.
Ireland	325,174	29,322,641	1 in 63.
Scotland alone	734,400	19,496,132	1 in 26½
Inverness-shire	118,818	2,723,501	1 in 22 9-10
Yorkshire	118,127	3,882,851	1 in 32 5-6
Sussex	101,318	934,006	1 in 9½
Great Britain, Ireland, Isle of Man and Channel Islands	2,512,231	76,318,648	1 in 30 2-3

It will be seen from this table that Scotland shows a slightly greater proportion of wood per acre than England; which, considering that the general character of the country a hundred years ago was bare and moorland, speaks well for the activity shown of late years by proprietors in planting, Sussex, in proportion to its size, is much the heaviest-wooded county in the British Isles. A notable example of the change for the better that may be wrought in a single lifetime occurs in this county (Wigtownshire). The late Earl of Galloway, who died in 1873, enclosed and planted a barren piece of moorland of about 1000 imperial acres in extent. He lived to see the entire character of the upland changed by his work. From being a featureless, bleak, unprofitable waste, it has become a luxuriant woodland, and the adjoining land has so benefited by the shelter that rich crops are grown up to the very fences of the plantations, and all traces of the moorland are well-nigh gone. Of course much depended on the enterprise of the farmers, which was forthcoming; but a main element in the change is the shelter of the woods, which are composed principally of Larch, Scotch Fir, Spruce, and Oak. There is now an extent of wood of sufficient size and sufficient variety spread over the country to enable us to judge how and what to plant so as to best overcome the natural difficulties which must occur in an exposed district. These notes, although principally of a local character, and referring to the west coast of Scotland, may, it is hoped, be of use to some of your readers. The three principal difficulties which have to be overcome on the west coast of Scotland by the planter arise from exposure, sub-soil, and rabbits.

* One of these trees stood opposite the smithy at Ellon, in Aberdeenshire, and was blown down in January, 1875.

Exposure.

As regards this, we have only to use our eyes to appreciate the fierceness of the battle which the foremost rank have to wage with the Atlantic gales. But it is remarkable how the direct influence of the wind may be overcome by judicious management. Four, three, and even two ranks of well-selected trees on the windward side of a wood are capable of so lifting and sifting the blast as to allow those to leeward to rise, provided this forlorn hope receives timely thinning. Thinning is imperatively necessary for all woods, but especially for those on exposed sites, or on a thin soil. In some favoured inland districts trees grow as if they could not help it, in spite of neglect; but such is not the case when, approaching the coast, battle has to be done with constantly recurring gales. It is not an uncommon, but it is an ill-founded opinion that trees which are most exposed should be left thicker than those which receive shelter.

It is hardly necessary to say that trees depend for existence on their leaves, as certainly as animals do upon their lungs; a tree with scanty foliage is accurately analogous to a narrow-chested man. Trees grown close together have no room for lateral foliage, and bear only a mop of leaves at the top, and thus become narrow-chested. Now the tops of trees exposed immediately to the sea-breeze are precisely the parts that suffer most (the singed appearance must be familiar to all who live near the sea), therefore it is important that our forlorn hope or foremost ranks should have room to breathe laterally, should have sufficient elbow-room to clothe their sides with leaves. Besides, the very tops of the trees will suffer less in this way; for a moderately open mass suffers less than a wall-like hedge from the blast, which is gradually sifted by the former, but exerts full sway on the latter. What affects one end of the tree, is of equal importance to the other end; and ample root-room is as necessary to produce a healthy tree as head-room. It follows from what has been said that the windward side of an exposed wood deserves, and will repay, extra attention. Whereas the more sheltered parts may remain untouched till the usual time for thinning comes (at an age of ten or twelve years), a watchful and frequent removal of a due proportion of the four or five outer ranks of trees must be practised from a very early stage; they should never, in fact, be allowed to touch one another. It may seem scarcely worth the trouble, but it is of tenfold importance that the exposed trees should be allowed to develop roots and leaves to the full. In a sheltered situation trees may be run up into poles, and when thinned will feather down, spread into sightly specimens, and make timber; indeed, trees so treated are often eventually the best and most beautiful; but a sudden thinning of the exposed trees will let in the enemy, the advance guard will fall before the wind, having no root-room, or, if they stand, will be apt to become hide-bound from the sudden cold. It must not be gathered from this that the writer advocates a bare windward side—far from it; the object to be attained is that every tree standing on the key of the position should be furnished above and below ground to the utmost, which can not be obtained by periodical thinning, but by taking trees here and there as required. The extra labour involved will be amply repaid to the owner of the woodland. Another effect of sea exposure may be noticed in the prematurely aged look which is caused by the growth of grey Lichen on the bark. Although it does not appear to be hurtful to the tree, it is unsightly, and destroys the clean glossy look of health which is so pleasing to the forester's eye. Beech, Horse Chestnut, evergreen Oak, Holly, and most coniferous and evergreen trees suffer comparatively little; but Larch, Oak, Elm, Plane, and Sweet Chestnut are often quite hoary with it. This growth is sometimes attributed to the effects of a damp sub-soil, but as it disappears in more inland places, it probably arises from the constant damp caused by salt encrustations of sea spray, which is often carried several miles in a heavy gale, and may be readily observed on window-panes near the sea-coast.

Sub-soil.

The next difficulty which offers itself very generally in Scotland is the unkindly and uncompromising nature of the sub-soil, which frequently consists of glacial till. It is quite

impenetrable to the roots of trees, and retains wet about them when they spread along the top of it. Sometimes it comes to the surface, in which case nothing can be done with it, but fortunately there is, as a rule, a stratum varying in depth from one to several feet of good soil, loam or alluvial, over it. Over a great part of southern Scotland the average depth of this fertile stratum is not more than 12 or 18 in., so here we are brought face to face again with the necessity for early and regular thinning, so that the roots may acquire in area what they are denied in depth. The proximity of the till should be borne in mind when undertaking the transplanting of large shrubs or specimen trees. If the sub-soil be scooped out, a basin is formed, which retains the water about the roots, and the loss of the plant must follow. Where it is necessary to remove large-sized plants a drain should be cut to form an outlet for the water.

Rabbits, &c.

The third enemy on our black list is the rabbit, and if the damage done in past and present times by this little animal could be reckoned, it would amount to a sum so huge as to justify the forester in considering it one of his principal foes. Of course it has many good qualities; rabbit shooting is capital sport, and rabbit broth is excellent stuff, not to mention rabbit pie, rabbit smothered in onions, &c., &c., but, from the forester's point of view, it is to be wished that they were all smothered—in something. There is no remedy but extinction. As long as there is a couple of rabbits on the ground you will find your Laburnums and Hollies gnawed; sometimes large trees are gnawed right round. Of course much may be done on a small scale by enclosing newly-planted trees with wire netting, and there are mixtures which should be applied to the stems of specimen trees. One of the best of these, and quite effectual, is composed of a solution of quicklime and water mixed with cow-manure. Plenty of the latter savoury ingredient should be put in, both to make the plaster adhere, and to give it a greenish colour when dry, otherwise it dries too white. Another excellent protective fluid is sold by Messrs. Davidson & Co., of the Scotch Colour Works, Leith, of which a 56 lb. cask has lasted here for three seasons. It is inexpensive, and being transparent, is hardly noticeable on the bark when dry. Care, however, should be observed not to use it upon very young coniferous trees. There is fortunately one beautiful and valuable forest tree which rabbits, as a rule, will not touch, namely, the Corsican Pine (*Pinus Laricio*), a tree which is now not much dearer than Larch, and the timber of which is said to be very valuable.

Trees and shrubs recently planted have special attractions for rabbits and hares, and most trees are safe when they have attained a certain size; but there are two ornamental trees which are never safe, namely, Hollies and Laburnums; the largest and finest specimens are as likely to be attacked as young saplings. Hard-wood are more liable to the attacks of ground game than Firs, especially Elm and Ash. The Leith mixture above mentioned, though injurious to very young Conifers, does no harm to young hard-wood, and the stem may be anointed at the time of planting with comparatively little trouble and good effect; for, by the time the protection is worn off, the tree will be established in the ground, and be less likely to attract rabbits. Wood-pigeons, black game, and the rapidly increasing capercaillie in certain parts of the country, do much damage to young woods. The two latter feed upon the young shoots of Firs and other trees, and it is surprising what a mass of buds and twigs may be turned out of their crops. Wood-pigeons do a great deal of harm in a different way. Anyone who has walked through woods frequented by them about five o'clock on a bright summer morning, has doubtless been soothed; by the cooing of unnumbered doves, perched on the tree tops, their mates keeping house below. A beautiful sound it is, but that is just the time the mischief is done. Every pigeon sits as near heaven on a fine morning as he can, which, in a Fir wood, means on the leaders of the trees—at that season young and tender. In the leader of a young Fir is centred all the promise of a clean straight stem, pointing direct from the axis of the earth to the zenith. When this is bent aside, the tendency, especially of all the Picea or Silver Fir tribe, is to send up several leaders; the result being seen in double or treble stems,

instead of one fair clean shaft. Therefore the wood-pigeons, which are less easily kept under control than rabbits, may justly be looked on as injurious to young Fir woods.

Effect of Ivy on Trees.

The growth of Ivy upon the stems of trees should be vigorously checked. Beautiful as it is in all stages of its growth, so beautiful that here and there trees should be mantled with it for ornamental purposes—beautiful whether in dense, glossy carpets on the floor of an old wood, or swung in heavy masses from swaying boughs—beautiful on cottage porch or castle tower—yet it should never be allowed to climb trees which it is important to keep in health, such as memorial or specimen trees, or those grown for profit or protection. In a moist climate and on a genial soil, its growth is so rapid that it becomes no easy matter to keep it in check. The Beech alone almost seems not to suffer from it; at least the writer cannot recall an instance of a Beech tree smothered with Ivy. The Beech's bark is so smooth, its growth so vigorous, and its shade so hurtful to all other plant-life (except that of Truffles, which grow on or among its roots), that the Ivy does not seem to get a chance with it. But from all trees with a rough, soft, or thick bark, it should be removed before it has time to grow to any size, or it will be difficult to do so without injuring the bark, a point to be observed, especially in dealing with some of the Fir tribe. Almost everywhere else Ivy is welcome as the most beautiful climber in the world. It is a mistake to think it makes a house damp. On the contrary, as long as it is kept from penetrating crevices, and running under the eaves or into window sashes, it makes a house dry; it acts as a waterproof covering, and protects from frost and weather. Then as to beauty, many an ugly house might be made, if not architecturally beautiful, at least home-like and picturesque; and many a flimsy cottage would be all the warmer and prettier for a great-coat of Ivy.

Season for Planting.

There is no subject in forestry which has been so amply discussed with less unanimous conclusion than that of the best season at which to plant. The climate of these islands is so variable that perhaps it has been found impossible to lay down an universal rule. It is, indeed, possible, with sufficient care, to plant or transplant at any season with success; at the same time, certain conditions are so obviously desirable that certain seasons ought reasonably to be preferred to others. Two main objects should never be lost sight of, namely, that newly-planted trees should not, if possible, be exposed to protracted drought, and that the warmer the soil at the time of planting the better. For that reason we should exclude the months of February and March, the months of all others during which the temperature of the earth is lowest, and when searching winds and dry weather may most safely be predicted. Nevertheless, it is exactly at this time that a great deal of planting in this country is done. Evelyn's seventh Aphorism (Sylva, chap. xxxii.), contains sound advice:—"Begin to transplant forest trees when the leaves fall after Michaelmas; you may adventure when they are tarnished and grow yellow; it is lost time to commence later; and, for the most part of your trees, early transplanters seldom repent; for sometimes a tedious bind of frost prevents the whole season, and the baldness of a tree is a note of deceit; for some Oaks, Hornbeams, and most Beeches, preserve their old leaves till new ones push them off." The best modern opinion is decidedly in favour of autumn planting, both for Fir and hard wood. The work is best done when the summer's growth is ripened and the sap is falling or about to fall. The ground is then of a kindly warmth, the roots will take hold at once before the winter's storms and frost are upon them, and the plants will be quite ready to start away in spring, which is out of the question when planting is delayed, as too often from choice or necessity it is, until February or March. This much may be laid down as a safe rule, that deciduous trees transplant best when near the close or just at the close of their period of growth. With evergreens no such law can be laid down. It certainly appears that in ordinary planting Firs do best in autumn. But planting or transplanting specimen trees or shrubs, where sufficient care can be taken to prepare pits beforehand, and to transfer

the plants at once from the nursery to their new position without allowing the roots to dry or the young shoots to flag, can best be done in May or June. Pines and Cyresses receive hardly any check treated in this way; and Hollies, though they frequently shed every leaf, very quickly recover, and grow away as if nothing had happened.

Mixed Planting.

There is a practice in this country which is in many ways objectionable, and which ought to be discontinued, or at least modified in degree, for it is unprofitable and unworkmanlike, and that is the system of Mixed Planting. It originated, no doubt, when woodcraft became generally revived, a reaction having set in about a hundred years ago (in the North, at least) against the long prevailing custom of stripping the forests off the face of the country. It arose probably in great part from a want of experience in the behaviour of different trees upon varying soils. It was considered that the simplest way to find the most suitable trees to plant them in such variety, that those which were best suited to the soil might eventually grow away and form the wood. It was a practical solution of the question, "What is the best tree for such and such a soil?" But it was, at best, only experimental, and we ought now to have acquired such knowledge and skill by observing the results, that we should be able to plant more scientifically, and select with judgment the species best suited to the soil. With such knowledge, it is a wasteful and slovenly method to stick trees in pell-mell to fight it out among themselves. It is a far higher art to map out a woodland, and be able to say:—"Here, in future years, shall be a grove of Beeches—there, a glen of Oaks; that hillside shall be dense with Pines, and along the crest shall tower rank after rank of Silver Firs." That is Nature's rule. You do not often, in natural woods, see one subject frittered away into another, but the secret of the effect is the ordering of the masses. Woods thus planted are not only more beautiful, but are apt to be more remunerative. Of course, the trouble of laying out is infinitely greater, and requires more brains; but the after management is infinitely simpler. Anyone who has marked a wood for thinning, will agree how much easier it is when the wood consists principally of Oak, or Fir, or any single class of tree. In a mixed wood, one is constantly worried to decide between this Oak and that Sweet Chestnut, this Silver Fir or that Scotch Fir, and so on. Then, as to beauty, the effect of masses correspond very much with what is called breadth, in painting. A master of breadth will so manage his materials, as to present to the eye on a few square inches of canvas or paper, the effect of a wide expanse of air, or light, or gloom. So it is in landscape. A master of breadth will so dispose his woods, as to give the effect of a forest in the ordinary bounds of a gentleman's park. The object of park scenery is professedly to please the eye; the eye cannot rightly be pleased without the sympathy of the imagination, and how can the imagination be pleased by a system so evidently artificial as mixed planting? Compare the effect of a single Scotch Pine standing among a mass of Beech, Elm, and Oak, with the effect of a healthy hill-side clad with a solemn company of 1000 Scotch Pine, broken here and there, it may be, by a lightsome glade of Birch. And would not the effect of the last be marred, be lost, if Pine and Birch were planted alternately throughout the mass? The pictorial effect of an avenue of old trees is often most impressive, and in many places forms the feature which distinguishes one park from another. The very nature of an avenue, to be perfect, requires that it should be composed entirely of one kind of tree. No matter what the tree is, be it Beech or Lime, Silver Fir or Oak, Yew or Plane, so long as there is but one species employed in the avenue, a character and peculiar charm is obtained, which would be utterly missed in mixed planting. There is another artistic effect obtained by the massing system, and a very important one as regards beauty. Each kind of tree allows different plants to thrive under it, and so gives a positive character to the ground. The floor of a Beech wood is bare and hollow, the silvery stems gleaming like marble pillars relieved against the ground of rich russet leaves; that of an Oak wood is often rich with greensward, or rough with Brambles and Holly; indeed no tree is more kindly to undergrowth than the Oak. Scotch Fir admit a deep growth

THE LIBRARY.

PICTURESQUE EUROPE.*

of Blackberry and Heather, even when growing very close, while Larch and Spruce spread beneath themselves a dense carpet of fallen needles, which admits of little growth except that of the male and lady Ferns, in such places often most luxuriant. Do not be afraid of monotony in this bold system of planting. Is there monotony in a regiment of Lancers—in a brigade of Guards on parade—more than in a motley crowd of all uniforms or no uniforms? It is this noble monotony which we see in the noblest natural scenery, in the Pine forests of the Tyrol or the Himalaya, on the heath-clad hill-sides of Scotland, even in the unnumbered multitudes of blue Hyacinths in many a home landscape in May. We do injustice to grand materials when we treat our parks, which should be natural pictures, with an ignoble want of breadth and character, and a frittering inartistic system of planting.

By these remarks it is by no means intended that all blending of foliage is objectionable; some of the most beautiful woodland effects result from the contrasting colour and form of different species. Only this should not, as it too often is, be left to haphazard; it must be the result of far-seeing design and artistic feeling. A most interesting occupation is thus open to one possessing these rare qualities, for, given the space to work in, the materials are practically inexhaustible. Trees and shrubs from the opposite ends of the earth may grow together with happiest effect. The grey silky foliage of *Pinus excelsa* from Bhotan increases in lustre when relieved against the sombre masses of *Pinus austriaca*; the effect of the blue crosslets of *Picea nobilis* is almost startling when seen in company with the greenest of all Pines—insignis. The groups and contrasts are endless; and so a higher purpose should be maintained in laying out ornamental woods than the mere object of covering so many acres for game or shelter. It often happens that rare and good plants, Pines or deciduous trees, and flowering shrubs come to hand at a time when it is not easy to find a proper place for them, and in such small quantities that it is not practicable to enclose a special piece of ground for them, and so valuable plants are thrust in between or even beneath older trees, where they never get a proper chance; and are overlooked, forgotten, and finally disappear, or are drawn up into weak attenuated eyesores among their more vigorous neighbours. This is, no doubt, a good thing for trade; but surely if it be worth while to buy expensive trees, it is worth the sacrifice of a bit of clear ground, of which centuries hence they may still be the ornament. Not long since the writer noticed a newly-made grave in a country churchyard. On either side of the headstone had been planted a hybrid perpetual Rose of the choicest sort; evidently with the intention of forming a little arch over the place where the head of the departed was laid; but alas! the hands that planted them were more loving than skillful, for the grave was overhung by an Elm tree, which cast so dense a shade that the Roses soon died. Young Conifers are so neat in habit that they are often planted far too near buildings. It is very absurd to see, as one often does, young specimens of the most gigantic trees in the world placed so close to the dining-room windows that when they reach maturity they must inevitably overhang or injure the house.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Evergreens under Trees (H. S.)—*Laurustinus* and *Rhododendrons* do well under trees also, and, particularly well, Hollies. Common Laurels and Yews are good, as is also *Bergreen Privet*. Among dwarfier plants the St. John's Wort and *Ruscus racemosus* do very well under trees.

Berry-bearing Aucubas.—Your correspondents who wish to have berries on their Aucubas should plant out the male Aucubas amongst the others. The first year they may not flower at the same time as the female plant, but they will do so in future years, when under the same conditions. I have at present two beds treated in this way, loaded with berries.—A. H. Thoreley.

A Large Seed Bed.—The Lawson Seed and Nursery Company commenced the present planting season with 30,000,000 one year old Larch seedlings, which are now nearly all sold. These were all sown last April and May, about 3 tons of seed being used. The young plants were from 3 in. to 5 in. high at the end of the summer's growth, and retain most of their leaves up to the present time, instead of losing them, as is commonly the case with seedlings from cultivated trees. This result is attained by employing the best Tyrolse seeds, specially gathered for the Lawson Company.

Dear Willow Leaves.—The leaves of *Salix alba*, and many other species of Willow are, it is said, employed in making a kind of Tea called *Tien-cha*, and are openly mixed at Shanghai with the Tea intended for exportation.

This is a remarkable book, and one with a great subject to deal with. It was no doubt suggested by, and will form a kind of companion volume to, Messrs. Appleton's noble "Picturesque America," which is so admirable for its designs and engravings. "Picturesque Europe," in its first part, is wholly devoted to Windsor, and has more space and illustrations devoted to it than is desirable, if anything like justice is to be done to picturesque England, leaving the wide world of picturesque Europe out of the question. The main interest of the book centres in its illustrations, which are numerous, large, and well drawn. The steel plates are of very good quality, but the woodcuts are not of the highest class; though spiritedly and well-drawn, a profuse spattering of hard white spots on inky blades produces a somewhat disagreeable effect. In this respect "Picturesque Europe" will not bear comparison with the delicate and rich engravings in Appleton's great book, or in those seen in the best French illustrated works. We speak thus plainly, through regret at the too evident imperfection of the art of wood-engraving in London. A great centre of literary activity like London should not be left so far behind in this respect. The illustrations in even the most successful of our monthly magazines, so suggestive of the besom and the inkpot, are a fair illustration of what much of our engraving is. Yet, so far as books are concerned, no art can be more precious than good wood-engraving, which, in its finest examples, has all the delicacy and more than the variety of steel or copper. Our main hope of improvement in this respect rests with the standard great publishing houses are satisfied with; and therefore we hope that as this great work progresses its wood-engravings will improve in delicacy of detail and truth and softness of gradation. The accompanying illustration is a representation of one of the scenes at Virginia Water, and a fair example of the best woodcuts.

HOW TO PLANT APONOGETON DISTACHYON.

I HAVE now in fine condition an example of this beautiful hardy aquatic, growing in a small tank originally intended for gold fish; but as my best endeavours to preserve the lives of the last-named proved futile, I thought it might be turned to horticultural purposes, and a plant of the *Aponogeton* coming in my way, I thought I could not do better than start it in the tank. This I did in June, 1875. I first of all laid some pieces of decayed turf on the bottom, and on this 1½ in. of rich soil; then the roots of the plant were spread out over it, and some more soil placed over them, and at the top other pieces of turf; then a few stones kept all in their place, and the tank was filled with water. In a few days the plant commenced to grow, and by August the lovely green oblong leaves quite overlaid the surface of the water, with the flower-stems coming up through them. Since then I have never been without flowers on the plant, and as it increases in vigour, the blossoms become larger and larger. A certain amount of decay of leaf is constantly going on, but a few water-snails, which find a home in the tank, act as scavengers, and there is no offensive gathering of matter. My desire is to press upon the attention of those who love flowers the cultivation of this charming aquatic; and that there should be no doubt as to the hardness of the plant, I may observe that it is growing in an unheated glass structure outside my dining-room window, and that on several occasions during the winter the surface of the water was quite frozen over, but without injury to the plant; in fact, it is hardy enough to grow and flower in the open air. As far as my experience of this plant goes, it does better in a cold house than in a warm one, which is an additional advantage. There are many odd places in a garden in which a small tank or pond might be constructed for the culture of the *Aponogeton*, while if kept near an open window, where it could have abundance of light and plenty of air on all suitable occasions, it would be found to make an excellent window-plant. A cold house—and there are many of them attached to the villa residences round London as well as all large towns; that are almost entirely unfitted for the growth of plants—is well suited for the culture of the *Aponogeton*, while the exquisitely fragrant flowers, reminding one of those of the Hawthorn in early May, amply repay the cultivator. Another great advantage is that it flowers most abundantly during the winter months.

Quo.

VIEW NEAR VIRGINIA WATER.

THE FLOWER GARDEN.

NEMOPHILAS.

NEXT to Mignonette no hardy annual enjoys so much popularity as the Nemophila. Before spring flower gardening became so fashionable, it used to be a common practice to sow a pinch of Nemophila seed early in autumn, in order that a mass of beautiful blue flowers might be forthcoming in the spring. For bedding purposes few hardy annuals excel the Nemophila; its habit is dwarf and neat, and a quantity of plants of it run into each other and form an even and compact

Nemophila discoidalis vittata.

mass of colour. In earlier days, when the old *Nemophila insignis* was almost the only variety known, some charming effects have been obtained in early spring by having beds of it edged with a neat margin of the white-leaved *Cerastium* or rosy pink *Saponaria*. In other cases mixed combinations of *Mignonette* and blue *Nemophila* are very charming, but however used, whether in pots, in window-boxes, or on rock-work, or in beds, it is always an effective plant. Now-a-days we find in the seedsmen's lists about twenty varieties of *Nemophila*. Although it is probable that between many of these

Nemophila insignis grandiflora.

the difference is infinitesimal, a selection of seven or eight kinds might, however, be made with advantage. To the *insignis* class has been added an improved kind known as *insignis grandiflora*, the flowers of which are large and of a clear bright blue, and a good companion plant to this is found in *grandiflora alba*, the flowers of which are pure white. In this section two new and distinct hues of colour have been added in the forms called *lilacina*, the flowers of which are of a pleasing shade of lilac; and *purpurea rubra*, which has puce-purple flowers, altogether a new hue in this family of plants. The *Discoidalis* section also includes some striking flowers, among which may be mentioned *ariculata*, a kind rich crimson-brown in colour with a white eye, and *vittata*, a

velvety-black margined with white. Another strong-growing section is that of which the type is *maculata*, a form well known for its large-veined and spotted flowers. The best representatives of it are *maculata alba*, which has white flowers blotched with purple, and *m. grandiflora*, white-veined and blotched with purple. There is also a variety in which the foliage is variegated. Among the forms of *Nemophila atomaria* are some very attractive, dwarf, compact-growing kinds that are well adapted for small beds or edgings; these are *atomaria coelestis oculata*, clear blue, blotched with black; and *atomaria elegans*, the flowers of which are pure white, with a dark chocolate centre. The periods of the year at which *Nemophila* seed should be sown are early in August for spring flowering, and April for summer blooming. In order to secure a good display of flower, however, the best time is to sow in August, on light soil where the seed can germinate freely, and the plants will not acquire too robust a growth before winter sets in. If it be possible to sow the seed where the plants are to flower, the results will be most satisfactory; but if transplanting be necessary, it should be done early in the winter, when a ball of earth should be attached to each plant, and to secure this thin sowing is indispensable. As a plant for the decoration of window-boxes, the *Nemophila* has few equals. A box 6 in. in width will afford a delightful display of bloom, if it have a back row of *Mignonette* and a front row of blue *Nemophila*. Good-sized pots filled with plants of *Nemophila* are worthy of a place in the conservatory or verandah; indeed, the uses to which this beautiful hardy annual may be put are so numerous that it would be difficult to say where it would be out of place.

A. D.

VASES AND VASE PLANTS.

THE use of vases in connection with terrace gardens becomes almost a necessity, and, in many cases, they form both an interesting and attractive feature when used in moderation, giving quite a finished tone to the terrace wall or balustrade, which was only needed to make the general appearance of the grounds complete. But too frequently, instead of half-a-dozen really noble-looking vases in which plants would flourish and would have an imposing effect, there are substituted fifty small ones, wherever the ingenuity of the designer could find a plea for placing them, and in which nothing but *Aloes* or *Geraniums* can exist. In the cultivation of plants in the open air the least experienced grower will acknowledge the necessity of protecting the roots from the scorching rays of the sun in summer and the action of frost in winter, by plunging (if in pots) and by mulching in open ground. But plants in vases, from their elevated and generally exposed positions, are calculated to feel the full force of both with the greatest severity. In the case of small vases, from the thinness of the stone and the small quantity of soil which they contain, the power of the sun's rays is so severely felt that it is a difficult matter to maintain the vitality of even the least sensitive subjects, as stagnant moisture is even more speedily destructive than drought. These contrivances may be termed plant-destroyers, for, when used on a large scale, nothing but a reserve stock of plants will suffice to keep them presentable. But really good vases are, when well furnished, attractions and valuable additions to any garden. They should, in the first place, be made sufficiently substantial for the sides to form ample protection for the roots of the plants against cold or heat, and should contain soil sufficient to retain moisture for several days when once thoroughly saturated. If these simple requirements be not provided for, together with good drainage, it is almost hopeless to expect a successful result. In the planting of Vases, the best results are generally obtained by individual taste in disposing of the materials at hand, rather than by any strict adherence to orthodox rules. But it is well to bear in mind that it is better to exclude anything from the arrangement altogether, even if a choice plant, unless it is well known to succeed in such a situation. A really healthy vigorous plant of *Yucca recurva* is far superior in effect to the best coloured *Dracæna* that is evidently not enjoying its position. But there is such a wealth of materials thoroughly adapted to the purpose in both foliage, flowering, and trailing

plants, that it will not be for lack of suitable subjects if a successful result be not achieved. When vases are arranged in pairs, it is of course advisable to fill them so that they may not only match, but the effect will be greatly improved by contrast if alternate pairs be filled with such graceful plants as the Yucca recurva and Ivy-leaf Geraniums, and the next pair with erect stiff-looking plants as the variegated American Aloe and Scarlet Geranium, edged with trailers, as upon the thoroughly furnished look of each vaso will depend success or failure in the decoration. To clothe the outer edgings effectively, a small wire to which trailing plants can be attached is necessary, for if allowed to be swayed by every wind that blows, they are very liable to receive injury from the sharp edges of the vase. J. G.

HARDY SPRING GARDENING.

On the choice of a suitable position, combined with a proper selection, will depend the amount of success that will attend our efforts in the cultivation and development of hardy spring flowers. If we take the Primrose, by way of example, we shall find that conditions suitable to its growth will suit such hardy bulbs and roots as Snowdrops, Aconite, and similar plants. I lately saw a bank under the shade of Filbert bushes completely carpeted with these earliest and loveliest of flowers; they had not been disturbed for years, and beyond the annual dressing of decaying leaves that fell on them in autumn and formed both a protection and a stimulant, they received no attention whatever. This is the condition under which we have the most profuse displays of Primroses in our woodlands; for neither under the deep shade of Evergreens, nor under full exposure to the elements, do we find such a vigorous development as in the plantations of deciduous trees and underwood, where they obtain nearly the full benefit of light until their season of flowering and leaf-growth is completed; and, as the shade of overhanging foliage increases, they ripen off gradually, and rest protected alike from heat, drought, or excessive moisture, until the autumn rains start them into active root-growth, and under their mantle of fallen leaves, they slowly but sturdily emerge into full life, ready to expand with the first rays of sunshine in early spring. In such positions the soil becomes completely carpeted with Moss and small herbage, so that the delicate blossoms are not splashed and soiled as in loose, freshly-dug soil; and they are screened from the withering effects of winds, which are even more trying to this class of plants than frost. Such positions cannot always be secured within the limits of the flower garden, but recesses or edgings of woodland walks, or connecting links between the cultivated grounds and woods may be rendered attractive, especially in the early spring, by the addition of such hardy roots or bulbs which, once established, will take care of themselves, and always yield a pleasing return. In the geometrical garden such hardy bulbs as Snowdrops, Crocuses, and Aconites are seldom very attractive in the spring, as they require to be in tolerably large masses to be effective, which can only be secured by providing an undisturbed root-ground; for this purpose I find no better position than that of utilising the broad bands of Ivy that now form so pleasing a feature in flower gardens, more especially those edged with stone or terra-cotta, for even if planted in small patches at first, they quickly increase in their congenial position, and when in bloom the effect is excellent from the contrast of the delicate blooms resting on a groundwork of dark foliage. In a band or edging of Ivy 18 in. wide, three or four rows of bulbs will have ample room to extend, and, when well established, will form quite a sheet of bloom, both flourishing under similar treatment. When the Ivy is clipped and pegged down in summer, a slight top-dressing of thoroughly decayed leaf-mould and soil will assist in keeping up a vigorous growth on both Ivy and bulbs. J. GROOM.

Edgings for Flower Beds.—Allow me to inform "Edinburgh" (see p. 200), that, after trying many different plans, I have come to the conclusion that nothing is so good as rough stones placed upon, not sunk in, the ground. Box harbours slugs. Tiles act as a dam, and make the ground very sodden. With a little management rough stones look well, and the plants will trail over them.—H. N. ELLACOMBE, *Bilton Vicarage*.

A MIXED GARDEN.

The garden of which I am about to speak, says a correspondent of "The Gardeners' Magazine," is located in the midland counties, but I should be guilty of a breach of confidence were I to indicate its exact position. Its most striking peculiarity is the remarkable manner in which a large number of the most useful esculents are made to contribute to its adornment. The grounds are fairly enclosed, and not open to the inspection of those who pass along the road. Near the house is a breadth of turf, with a few beds of losses round the outside, and beyond this are groups of trees, clumps of shrubs, and winding walks. The space beyond the breadth of turf is not very large, perhaps not more than half an acre, yet from the manner in which it is broken up by the groups of trees and shrubs it appears to be very much larger. In this part of the garden, which may be considered as an equivalent to the "wild garden" of a more pretentious establishment, B— has developed what to me is quite a new idea in wilderness decoration. Round the boundary are clumps of fruit-bearing trees—here a clump of Apple trees, there a group of Cherries, yonder a knot of Pear trees, and so on. Planted in this way they do not give an orchard-like appearance to the place, and the principal objections that could be urged against planting fruit trees in pleasure grounds are cleared away. B— who is unacquainted with the choicer kinds of flowering trees and shrubs, said to me, "The Apple, Pear, and Cherry trees are as pretty when in bloom as any of the trees that do not bear fruit of any value excepting to the birds, and I do not think the fruit which follows the flowers at all objectionable; in fact, I like to see it, and, as the few friends who drop in to have half an hour's chat or a bit of dinner enjoy as well as myself a good Apple or Pear, I do not see why I should not plant trees bearing fruit instead of those producing flowers and a few worthless berries, or that do not flower at all." I felt at the time, as I saw the Apple and Pear trees laden with fruit, and I feel now, whilst writing this, that the view of the the matter taken by B— is not far from right, so far as a garden of small extent is concerned.

But the idea of B— for combining beauty and utility is not confined to the fruit-trees, for on the turf are beds of Globe Artichokes, which in appearance are quite unsurpassed by any of the coarse forms of hardy vegetation, or, indeed, by any of the "sub-tropicals" so called; and from these beds an abundant supply is obtained throughout the season. Other beds are filled with Cardoons, also ornamental in their way, and with the little labour required for blanching the stalks, a considerable addition is made to the stock of vegetables available for the table in the late autumn and early winter months. I was at first doubtful as to the capabilities of the household for cooking Cardoons, but when B— began to talk about boiling them first in clear water until the skin could be easily removed, and then boiling a second time in good stock and serving hot with rich brown gravy, my mind was soon set at rest upon this point, and I was sufficiently convinced that B— knew how to have vegetables of the choicer kinds cooked as well as he did to cultivate them in a manner that whilst good crops were produced they were made to contribute to the interest of the garden. Quite at the back of the borders were large clumps of Jerusalem Artichokes, and although they are rather coarse, they are very bold in appearance, and with a foreground of shrubs and other plants of less stature they are not wanting in effectiveness.

One of the greatest surprises was the employment of the Asparagus as a decorative plant, and, disposed at intervals in clumps, it was wonderfully attractive, for in elegance of feathery spray it has but few equals, and when studded with its brilliantly-coloured berries its attractiveness is materially increased. The clumps were about a yard across, and I can well believe that in the course of the season there was no difficulty in obtaining a good dish whenever required. The Seakale and Variegated Kales were also planted at intervals, the former close to the edge and the others farther back. The glaucous leaves of the Seakale afford a striking contrast to the deep green and bronzy foliage of surrounding subjects, and a supply of excellent quality is obtained by heaping sand over the crowns and then putting inverted flower pots over these, and by lifting the roots, and after they have been put in boxes with a little soil about them, placing them in a cellar. Crowns that are not covered or lifted produce flowering shoots, which may be taken off before the flowers expand, and be cooked in much the same manner as Asparagus. I have eaten them several times, and thought them delicious; and by mentioning the fact to B— I had no doubt I should be able to surprise him; but was very much taken aback by his saying, "Yes; the green stems are very good, and I like them so much, and they come in so useful, before the Cauliflowers and several other good things, that I leave nearly half the Seakale crowns alone." B— is also very partial—so at least he told me—to the Indian Corn cobs when cooked whilst young and tender, and served with a liberal quantity of butter. Of the table Maize there was consequently a

number of clumps in the borders, and several beds also, and they certainly gave a tropical-like aspect to the place. Beetroot was necessarily represented, for it is one of the most ornamental vegetables we have, and when, as in this instance, groups of six or seven roots are arranged alternately in selected positions with the Seekale, the fine deep colour of the foliage is brought out to great advantage. Rhubarb was rather extensively planted in the more spacious borders, and the masses of green leafage were very attractive, much more so than might have been expected.

Scarlet Runners were planted in various suitable positions similar to those occupied by the Jerusalem Artichokes, and in doing this some amount of taste was shown; for when they are close to the eye they are rather coarse, but at some distance off the scarlet flowers have a bright and effective appearance. So far as I could see, the Beans were sown in a ring about 30 in. in diameter, and feathery Peasicks about 6 ft. in height employed for supporting the twining growth. These also presented unmistakable proofs of bearing abundantly. Tall Nasturtiums or Tropæolums were grown in a similar manner, but in positions more immediately under the eye. Along the front of some of the borders were patches of the dwarf Tropæolums. The Nasturtiums are grown for the sake of their bright flowers, and for the seeds, which are gathered when about half grown and pickled, to form a substitute for Capers. *Martynia fragrans* is also grown in quantity, as the fruit is very good when properly pickled. The Purple Orach formed a conspicuous feature here and there, for a few large clumps will furnish a plentiful supply of leaves for cooking as Spinach, and the plant is sufficiently ornamental to be sown in shrubby borders, from which there may be no desire to obtain a supply of vegetables. The Gourds and Vegetable Marrows had a place assigned them on a bank in the wildest part of the garden. Some years before a large heap of pieces of stone, broken columns, and soil was formed, and I considered it a happy thought of B—— to clothe it with these rampant-growing subjects. "For many years," B—— said to me, "I did not know what to do with that heap of stuff, for it was always smothered with weeds, and had a most unsightly appearance, and helped to fill the garden with weeds. At last I made up my mind to plant Pumpkins and Marrows, and they have done all I expected of them in keeping down the weeds, and we have in addition plenty of tender Marrows in the summer and ripe Pumpkins for pies during the winter." The large sorts appeared to be preferred to the small and more delicate kinds, but it was evident that B—— prided himself on the size which both Pumpkins and Marrows attained. A warm sunny position on the bank, where it consisted almost exclusively of stones, was devoted to Tomatoes. These were planted between the blocks of stone where a sufficiency of soil could be found, and the shoots were allowed to ramble about over the stone without being stopped or in any way regulated, and, as was sufficiently evident, good crops are produced without the stopping and training considered so essential in their cultivation, and indeed necessary, when they are planted in a rich border at the foot of the wall. In the foregoing remarks I have merely glanced at the more prominent features of this curious garden; but it appears to me that much might be written in reference to the planting of vegetables of an ornamental character in the semi-wild parts of the gardens of limited extent.

Pond Weeds.—Would any of your readers give me the benefit of their experience in clearing a pond from Water Milfoil? I have a piece of water, some 3 acres in extent, that has become so choked up with it as to be unfit for either fishing or boating. What I should like is the experience of some one who has been successful in eradicating the pest, not mere suggestions; of these I have had too many already at serious cost, including dragging it out with grappels, but the results have not been worth naming.—LANCASTRIAN.

Formation of Gravel Walks.—If Mr. Edwards, of Bath (see p. 190), will make his gravel paths as follows, he will get rid of all the disagreeable matters of which he complains, viz.:—Set out and properly form the edges by digging, well treading, and levelling; then dig out the box (the technical name for the space between the edges) to the depth of 12 in., put in a 3-in. agricultural drain-pipe in the centre, 2 ft. under the "formation" level, for thoroughly underdraining the ground, and for carrying off surface-water from the path, collected in small cesspools, covered with iron gratings 100 ft. apart, and placed alternately on each side of the walk, and communicating with the centre drain by 2-in. pipes. The path, when finished, should have a convexity of 2 in., so as to throw off the surface-water quickly, and the "formation" should have the same convexity. When the drains and cesspools are finished, lay upon the "formation" a good layer of fine brushwood, which will occupy a depth of 1½ in., when compressed by the weight of the other materials; upon this lay 6 in. of chalk, hard-core, burnt ballast, or coarse gravel. Well

consolidate by means of a heavy roller, cover over with a layer of fine house-ashes 2 in. in thickness, which will obviate disturbance from worms, and finish off with 2½ in. of fine garden gravel, which, if laid on in dry weather, should be thoroughly soaked through with water before rolling. I have adopted the foregoing formula for twenty years, and the result has been all that could be desired.—X. Y. Z.

THE OXALISES.

Owing to the beauty of their flowers, several species of *Oxalis* make good bedding plants; some of them are also very sweet-scented, and of these *O. odorata* is one of the best; its flowers measure about half-an-inch in diameter, and in colour are a beautiful shade of bluish-pink. For bedding, the most effective kinds are those that have large flowers, such as *Bowcana*, which I have seen bedded out in

Oxalis rosea.

Battersea. *O. Deppoi* has flowers of a pinkish-lilac colour, about half-an-inch in diameter, and, as it flowers in bunches, it makes a good bedding plant. Its leaves have a dark stripe round the centre, something like those of *tetraphylla*; its bulbs are also similar to those of that variety. In addition to those named the following are all hardy and useful for bedding purposes, viz., *arbores* and its varieties, *cornorensis*, *articulata*, *flava*, *digitata*, *floribunda* (rose and white), *pectinata*, *purpurea*, and its variety *laxula*, *latifolia*, *casiopeata*, and its flesh-coloured variety, *lactiflora*, *violacea*, *versicolor*, *tetraphylla*, *spectabilis*, *Schilteri*, and *rubella*. Of kinds generally grown in pots in the greenhouse, *O. rosea* is one of the best; it

Oxalis Deppoi.

Oxalis Valdiviana.

has flowers singly (not in bunches), over 1 in. in diameter, and bright rose in colour; in habit it is dwarf, with an abundance of pale green leafage. Other greenhouse varieties are *compressa*, *lanata*, *rosacea*, *arbores lutea*, *rutilans*, *lasiandra*, *elegans*, *asinina*, *filiculis*, *bifida*, *leporina*, *lobata*, *caprina*, *floribunda* (*rose*), *variabilis* (red and white), *cernua* and its double-flowered variety, *fragrans*, *venusta*, *Cervantesi*, *grandiflora rosea*, *hirta rosea*, and *hirtella*. For bedding out, those that flower singly are preferable to those in bunches. I never remember seeing a better substitute for the beautiful *Leptodactylon californicum*, which I once saw in perfection at Shrubland Park than *O. Bowcana*. R. H. B.

Sisyrinchium grandiflorum.—This is my favourite spring flower—a lovely mauve-purple. It seems to like a north border. Few people know it.—FRANKSELLA.

Griffinia ornata.—This is described as a very ornamental species. It was imported from Rio during the past season, by Mr. Bull, with whom it has been in flower during the winter. It is distinct from the older and better known members of the same genus.—Q.

THE KITCHEN GARDEN.

CULTURE OF BROCCOLI.

EITHER Broccoli or Cauliflower may be had fit for use every day in the year, and where these are consumed on a large scale, a good plantation of winter and spring Broccoli is valuable. In the moist atmosphere of Lancashire, with its dense smoke and clay soil, cultivators are put to their wits' end to find out the best way to procure a supply of Broccoli from January to the end of May, when early Cauliflower begins to come in. To accomplish this I have had recourse to many expedients, but I find the following system to answer best:—The seed should be sown thinly in drills at the beginning of April, and as soon as the plants can be easily handled, the best of them should be drawn out of the seed-bed, and replanted on a well-prepared border, trodden solid, from 8 in. to 10 in. apart. As soon as they have attained a fair size, and have become well rooted, a spade should be run down the centre between each row, cutting the roots in such a way that each plant may be lifted with a good ball attached to it. Any extra labour incurred in this matter is afterwards well repaid, as it tends to keep the plants dwarf and bushy. During the autumn or winter months, according to circumstances, the ground to be planted should be trenched two spades deep, and in the bottom of each trench should be placed some half-rotten manure, consisting of old Pine stools or other refuse of a rough character, which will keep the soil open, and which will form good drainage, without which our labour will be in vain. The surface should be left in a rough state until planting time, when, if the weather be favourable, 2 or 3 in. of good rotten manure spread on the surface should be worked in with a four-pronged fork, leaving the ground level. Before planting, tread quite firmly, and allow plenty of room between the rows. In small gardens where ground is scarce, and too thickly planted, the whole bed has to be sacrificed in the winter. With Broccoli and surface-rooting plants care should be taken to use the hoe in as shallow a manner as possible, in order that the roots may sustain no damage. About the middle or end of October, according to the state of the weather, an opening should be made along the side of the outside row; the plants having been cut round with a spade, should then be turned over on their sides, the head falling northwards, and amongst the roots should be placed some light manure, such as that taken from the top of the Vine borders, mixed with short Grass, the whole being covered over with soil. The manure in a short time will be found full of white roots, which strengthen the plants against severe weather, and cause them to produce finer heads than they otherwise would have done. I have tried the soiling up system, and have placed litter between the plants, to protect them from cutting winds, but nothing answers so well as the heeling-in system: I have generally found when the plants have to be removed from where they have grown, that they stand the winter well, but that they never make such fine heads. As regards varieties, every one has his own favourite. I find the following to stand best (but I should state that I have not grown several of the newer sorts):—Backhouse's Winter White, Knight's Protecting, Wilcove's Late White, and Brimstone or Portsmouth; the latter stands the best of any which I have grown.

Waterdale, St. Helen's, Lancashire. JAMES SMITH.

HEELING-IN BROCCOLI.

"A D." stands completely alone in condemning this practice; cultivators would dispense at once with the labour of heeling-in the plants in autumn were it not imperative. I have tried both ways, and seen others do the same both in England and Scotland, and always with the same result. The check given by heeling-in, if done in time, say not later than the end of October, hardens the tissues, and in this lies the whole secret of the matter as far as resistance of frost is concerned. "A D." may just as reasonably say that an ill-ripened Peach shoot is as safe in a severe winter as one that is well ripened. He says if heeling-in be done, it should be done at the end of August. Is he not aware that in many places Broccoli is not planted till near the beginning of August, and that the plants grow almost as much in September and October as at any other time?

For this reason, we never heel-in here (in South Yorkshire), till the end of October, and after that period the plants not only root sufficiently to get established again, but grow considerably. S. W.

For these seven years past my Broccoli has been planted after Strawberries, the only preparation being to cut up the Strawberries and plant the young Broccoli plants with a crowbar. The soil being solid appears to suit them well. They grow dwarf and sturdy, and are short-legged; if the weather be unusually sharp, we cover them up with Bracken, which is light and airy. By these simple means we are rewarded with a bountiful supply of good Broccoli from early in winter to the end of May.

R. GILBERT.

Common Errors in Celery Culture.—It is not my intention, says a correspondent of the "Florist," to enter into the details of the ordinary culture of this useful vegetable, because they are well understood, but to notice three common errors connected with its growth. The first I will mention is that of sowing too early. Although Celery is a biennial, yet when the seed is sown too soon—say the 1st of February—and the plants are nursed a little, they are very liable to "pipe" or run to seed; while those raised from seed sown about this time of year seldom do so. The second error is that in earthing up the plants too much soil is applied at one time, by which the hearts are covered in, and they are thus made to bulge out on one side, and become deformed; whereas, when the operation is more lightly done, as well as oftener, the heads are kept upright, and the growth is much more vigorous. The third error I have had to notice, and which is, perhaps, the worst, is "earthing" or banking up the crops too heavily in autumn or before winter sets in; this is a very common practice, especially among cottagers, who often cover their Celery over head and ears, if I may so express myself. This, moreover, is done with a view of keeping out the wet and frost from the crops; but in such cases the Celery fails to grow from want of air; in fact, as already indicated, the plants are buried, and they soon become rotten; and, though the wet weather may be blamed for this, it may even happen when the ridges are covered with litter or boards. Formerly I used to fall into these errors above mentioned; but now I earth up my Celery more sparingly, taking care that the leaves or tops of the plants are well above the ridges, especially in the case of late crops. Hence I have had no reason to complain of my crops rotting, however damp and severe the winter may have been. Those who protect the ridges to fence off the weather, seem to overlook the fact that the means employed for this purpose prevent the escape of moisture by evaporation of the earth, in consequence of which the crops are more apt to rot than if their tops had been freely exposed to the air.

Planting Asparagus.—I always plant my Asparagus in single rows, 3 ft. apart and 18 in. from plant to plant. It is convenient for cleaning, gives the roots room to spread without interlacing or struggling with each other; and, although the plants are planted on the flat, an annual top-dressing with manure over the crowns, and the treading between the rows, cause the latter to assume the form of a ridge, which tends to throw the rain off the crowns, and prevents stagnant water at the most vital point; moreover, to have good Asparagus, it is essential that the early growths are not broken over by high winds. When such is the case, the later growths do not come so strong, and also lose time in coming to maturity. The above distance will not be found too wide to allow strong Asparagus to develop itself. Another point should be attended to where strong Asparagus is grown to be forced, that no seed should be allowed to swell on the plants—certainly none allowed to ripen. This is as essential as cutting the flowering shoots off Seakale or Rhubarb.—W. D. C.

The Calabash or Bottle Gourd (*Lagenaria vulgaris*), figured (see p. 209), is eaten by the poorer classes in India. The young fruit may be seen exposed for sale in slices in every market, and by vendors on the road-sides. When dried, the hard shells are used as bottles for holding water, &c. A variety of it is employed to make the stringed instrument called the Sitar; and also for floats and buoys for swimming across rivers. Some are elongated, and 1½ ft. in depth, while others are nearly round. A half-shell is also used as a dish for meat, rice, and similar material.—J. P.

Raising Seed in the Dark.—Sow the seeds in the usual way, cover up and keep in total darkness until they begin to peep above the soil, then gradually expose them to the light. For years past excellent articles have been written, advising shading seed-pans with paper, various coloured glass, &c., none of which methods approaches this system in merit, and why it has not become a general practice long since I am at a loss to say. The advantages and success of this system are so apparent that it only requires to be once known to become universally adopted; when a frame is covered with mats it ensures uniform moisture and temperature, consequently every seed possessing life will be sure to grow.—H. CANNELL.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

MARCH 1ST.

At this meeting, which was well attended, the most attractive features were beautiful groups of Orchids, Ferns, Palms, and other valuable stove plants, contributed by Messrs. Veitch & Sons and Mr. B. S. Williams. A very fine specimen of *Phalaenopsis Schilleriana* came from Mr. Bass's garden at Hangerstone, near Bournemouth, to which the Commodore recommended that the Davis medal should be awarded, on account of its superior culture. Mr. Bull furnished a beautiful double-white *Epacris*; and Mr. B. S. Williams showed one of the finest strains of fringed Chinese Primroses that we have yet seen.

First Class Certificates.—These were awarded to the following new and rare plants, viz.:

***Grevillea Fraxilli* (Rollisson).**—This is a distinct Australian species, which, as far as general habit of growth and glaucous hue are concerned, reminds one of the common Southernwood (*Artemisia Abrotanum*), each shoot being terminated by a cluster of bright rosy-crimson flowers. It is well worth attention as a decorative pot-plant.

***Epacris onosmæiflora* fl. pl. (P. E. impressa) (Bull).**—This is an erect growing plant, of strong habit with long decussate sharp-pointed leaves, of the deepest green imaginable. Its flowers measure about ½ in. in diameter, and are as double as those of a white *Camellia*, the colour being pure white. It is a valuable addition to *Epacris*, and one which will be largely appreciated by those who as a rule eschew the culture of hard-wooded New Holland plants.

Orchids.—Of these Messrs. Veitch contributed a large group, in which the following were particularly worthy of notice, viz., *Masdevallia nyctera*, one of the most grotesque of all Orchids, but by no means a showy one; *Lælia harpophylla*, a distinct species nearly allied to *L. cinnabarina*, and, like that kind, having vermilion-coloured flowers, but it is much more slender in its habit. Associated with these were *Dendrobium amethystiglossum*, a tall-growing leafy species, bearing pendent racemes of creamy-white flowers, having a delicate amethystine blotch on the lip; *Angræcum citrinum*, one of the most delicate of all the species belonging to this genus, bearing long slender spikes of creamy-white flowers; *Vanda conchulensis*, a little gem in its way, bearing one spike of bluish-purple-lipped flowers, and a new *Odontogloss*, seemingly intermediate between *O. Alexandræ* and *O. gloriosum*. Its flowers are exquisitely formed and very delicately coloured, somewhat in the way of *O. Andersonianum*. Among other *Odontogloss* were *O. Rossii majus*, *O. Roezlii album*, and *O. triumphans*, the latter bearing a long flexuose spike, furnished with nineteen flowers; also *O. Alexandræ* and *O. Poscatorei*, the latter having a fine branching spike, bearing seventy-four pure white purple-dotted flowers. Among hybrids in this collection we noted *Cypripedium barbatum*, with dark greenish flowers; *Dendrobium Ainsworthii*, an hybrid between *D. nobile* and *D. heterocarpum*. This plant was first raised and exhibited by Mr. Mitchell, gardener to Dr. Ainsworth, at Lower Broughton, near Manchester, and since raised from seed by Messrs. Veitch, from the same parents, a fact of some importance to hybridists. The same firm also furnished *Lælia flammea*, a cross between *L. cinnabarina* and *L. Pilcheri*, bearing orange-coloured flowers; a plant of *Ada aurantiaca*, bearing five spikes of vivid vermilion-tinted blossoms; and some other Orchids, among which were *Dendrobium crassinode*, *D. Wardianum*, *D. liliiflorum*, *D. formosum*, and *Phalaenopsis Schilleriana*, and intermixed with the whole were some very graceful dwarf Palms. In Mr. B. S. Williams's group we remarked *Calanthe Turneri*, *Cypripedium Dayii*, *Ada aurantiaca*, *Helcia sanguinolenta*, and other choice species. Two strong and well-bloomed plants of *Odontoglossum Alexandræ* were shown by Mr. Ollerhead, gardener at Wimbledon House; one bore three spikes, on which there were in all thirty-four flowers; the other one spike, on which there were twelve very finely-coloured blossoms.

Miscellaneous Plants.—Mr. B. S. Williams showed a choice collection of Ferns, fine-foliaged Palms, and Palms; among the Ferns we noted *Ceterach aureum*, a strong pinnate-leaved kind, nearly allied to *C. officinarum* and *Adiantum gracillimum*, the lightest and most fairy-like of all Ferns. Other plants consisted of the white-striped *Anterium*, *Andropogon*, a plant closely resembling *Pandanus Vitiensis* in habit and variegation; *Bertolonia Van Houttei*, and *Habrochama elegans variegatus*, two well-bloomed examples of *Eucharis grandiflora*, and two or three vivid scarlet *Amaryllids*. From the same exhibitor also came a dozen well-grown plants of Chinese Primrose, the colours of which were rich rosy-purple and pure white, the individual flowers being nearly 2 in. in diameter and elegantly fringed. Messrs. W. Rollisson & Sons, of Tooting, furnished, a basket of the sombre-looking, but deliciously fragrant, *Boronia megastigma*; also a new and unnamed *Delphinium*, from the West Indies, and a fine mass of *Erica* herbacea in full flower. Mr. G. P. Wilson contributed two new seedling *Heptacas*—one a vivid magenta, the other suffused with the faintest blush; also one a lance-leaved *Goodyera* from North America, having white reticulations on the leaves like those of *Arum italicum*. Mr. Ollerhead sent a double-spathed *Anthurium Scherzerianum*. A basket of very beautiful and fresh-looking hardy Primroses came from Mr. R. Dean; among these were yellow, lilac, white, pale, crimson, purple, and maroon-coloured varieties. Mr. Herbst, of the Richmond Nursery, furnished well-grown examples of *Lily-of-the-Valley* and *Spirea japonica*, both of which were much admired. Of the former one batch consisted of Dutch-grown roots, the last being very dwarf and in every way the best. Col. Trevor Clarke

showed flowers of *Iris stylosa*, a mauve-tinted species with larger blossoms than those of *I. histrio*, also examples of the rich purple-golden blotched *I. reticulata*, and flowers of an early form of the summer Snowflake (*Leucojum*); likewise flowers of *Cyrtanthus nuchellus*, a white-flowered Cape bulbous plant, the flowers of which are very slender and tubular.

Fruit and Vegetables.—Among fruit, was a dish of the old Colmar Pear, from the Society's garden at Chiswick, and Mr. Dixon (Holland House) sent a dish of Stone Pippin Apples, in excellent condition. Examples of black-coated Radish-shaped Turnips came from Mr. Thomas Maclure, The Gardens, Hartley Grange, Winchfield. A seedling Cucumber, named "Drayton Manor," came from Mr. Owen Thomas, gardener to Sir R. Peel, Drayton Manor. It was said to be a cross between Telegraph and Masters' Prolific, but it was not considered sufficiently distinct to deserve a certificate.

Golden Chickweed and Golden Thyme.—I saw this Chickweed in one or two places last summer in good condition; but I confess that, with me, in spite of a good deal of trouble taken with it, it was not satisfactory. I expect it requires to be planted early in the season, in a rather damp position. Except for the sake of variety, it is hardly so effective as the Golden Pyrethrum. With the Golden Thyme I am pleased. Our dry porous soil seemed to bring out the rich golden tint to perfection, and it bears cutting with the shears without looking ragged or stumpy. Some thousands of little pieces, dibbled thickly in cold frames in October last, are now well rooted.—E. HODDY.

Watering Indoor Plants with Ice-water.—At p. 170 it is stated that, "Two writers in the 'Revue Horticole' contend that the common practice of watering stove and greenhouse plants with tepid water is wrong. They consider they actually get a much better result by using the coldest water within reach." Permit me to remark, that neither M. Rougier Chauvrière's nor M. Henri Trichot's assertions on this subject are corroborated by proofs. They have not made comparative experiments on the same plants, and for the same length of time, with cold and tepid water, which, in my opinion, is necessary to prove that the one is better than the other. Besides, M. Rougier Chauvrière's plants are grown for sale; they never remain long in his possession and he cannot say what they become after he has sold them. M. Henri Trichot has, for a few days only, watered some of his plants with ice-water, and he cannot yet say what will be the result. I therefore maintain that the experiment is insufficient, because it has not been made comparatively. Plants, like animals, may live for some time under bad treatment, without showing signs of ill health, but that does not prove that the treatment is good. Those who grow vegetables for market about Paris, when they see the approach of rain in summer, hasten to the pumps of their wells and water their salads with cold water. Why? Because the rain would make the salad plants run up to seed, which the cold water checks. Is this a proof that cold water is good for vegetation? I hope that the matter will be better tested before horticulturists consider that it is settled.—JEAN SISLEY, Lyons.

NOTES AND QUESTIONS—VARIOUS.

Spurge Laurels for Undergrowth.—These should be cultivated more extensively than they generally are especially by those who prefer sweetly perfumed plants to glaring colours. They flourish well under the shade of tall trees, and form excellent edging plants for shrubberies.—J. GAOUD.

Camphorated Spirits of Wine v. Mealy Bug.—These I find destroy mealy bug, and by reducing the spirit's strength with water the most delicate-foliaged stove plants may be operated on without injury. It, however, requires careful and frequent attention to get rid of the pest, and the surest best used with a soft brush or a small piece of sponge tied to the end of a stick and washed on as softly as possible.—W. T.

Pear Ripening.—I should much like the opinion of fruit-growers, more particularly those in midland and northern districts, on this subject. *Burré Rance*, *Bergamotte d'Espèren*, both usually very good, this season do not ripen kindly, a circumstance which I attribute to the sunless summer last season. Earlier varieties have been fairly good, but still not up to the average.—R. GILBERT, Burghley.

Primula denticulata and other Early Kinds.—I have a good plant of this pretty early *Primula* in full bloom, and ere it has ceased flowering it will have produced fifteen or sixteen heads of blossom. It has already been in bloom for a month, and I anticipate that it will continue flowering for the next three months. It would appear to be the earliest of all the hardy imported kinds. Two other varieties, specially alluded to by Mr. Niven—*purpurea* and *pulcherrima*, are also showy flowers, the former having two strong trusses. *P. pulcherrima* has coloured foliage, and is a very distinct kind.—D.

Royal Bouquets.—At the State Concert which took place the other day at the Albert Hall, Her Majesty's Bouquet, furnished by Mr. Wills, was composed of *Roses*, *Eucharis*, *Odontocissus Alexandræ*, the chaste and beautiful *Coleogyne cristata*, *Violets* and *Lilies of the Valley*; that of H.R.H. the Princess of Wales contained *Neapolitan Violets*, the lovely *Dendrobium Wardianum*, *Lilies of the Valley*, and other valuable flowers; and that of the Princess Beatrice, various *Orchids*, *Lilies of the Valley*, *Eucharis*, and *Lilac*—the whole being surrounded by Brussels lace-holders.

"This is an art
Which does mend nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

LARGE SEEDS BEST.

It may be stated, without fear of contradiction, that few experienced cultivators are unaware of the fact that the brightest, largest, or heaviest, and newest seeds are, as a rule, the best and the most likely to produce the finest crops. This is an important fact, and one which, we can easily believe, is too often overlooked, even in these days of high culture. It is a matter, however, which concerns the seed-grower more than the seed-sower. The latter must take the seeds as he gets them; and, though he pays for both large and small, he can, if he likes, in the case of the larger seeds at least, such as Beans and Peas, Melons and Cucumbers, &c., put the small ones aside, but, with the great majority of his crops, any advantage he might gain by so doing would not recoup him for his trouble and expense. It is quite different with the seed-grower; it is his interest to grow a good article, and large seeds pay him best—such as are sold by weight, at all events—and the greatest bulk is sold in that way. Nearly twenty years ago, when we grew *Calceolaria* and other select seeds for the market, we realized the truth of this statement. It was a noticeable fact that weak varieties and weak plants, or plants with small flowers, generally produced the smallest seeds, and we soon discovered that it was really a question of culture whether a thousand plants, for sample, produced 8 ounces or 12 ounces of seed, for which "the trade" allowed from £8 to £10 an ounce. In growing the plants, the principle that old seed was the most productive was not acted upon; but newly-ripened seed was sown annually, which produced vigorous plants, and they in their turn threw up vigorous flower-spikes, which bore large flowers that produced large pods, crammed to bursting with glistening, heavy seeds that told a tale when put into the scales. Now, the *Calceolaria* is no exception, for it is just the same with all the seeds with which we crop our kitchen gardens, or furnish our flower borders. The gardener can always, to some extent, make up for want of vigour in his seedlings by generous after-treatment, and it is hardly credible how much can be accomplished in this way; nor must we forget that a poor seed-bed will never furnish strong plants, let the seed be ever so good; but it is a great matter to have good, heavy, and well-ripened seed to start with, for other things being equal, it will always give the best results. But is high culture the rule with seed-growers? Are our vegetable and flower seeds as large, and even generally as they might be? On this point we have grave doubts. The seed-grower's name may be said to be legion, if we include private growers of specialities, who claim to have good strains of certain subjects; but do they always "select," or do they only "save" their seed? It is to be feared that seed-growing, like many other matters, will always be a question of production with the least amount of expense, as regards those seeds which are in most demand, but with many garden seeds, such as Peas, Beans, Kidney Beans, seeds of the Brassica tribe, Melons, Cucumbers, &c., a certain amount of care in the culture of the plants and in the selection of the seeds is quite practicable, and would no doubt pay in the long run, for there is nothing more certain than that when a member of the trade becomes noted for a "good strain" of any particular plant, he is sure of customers. It is difficult for the sower to know the qualities of his seeds generally by mere examination, unless he has considerable experience, and even that will not always help him; still the practised eye, with, in some cases, the assistance of the microscope, notes certain indications, which generally guide the cultivator to pretty safe conclusions. It is first of all necessary to know the seed of any plant when one sees it; and, secondly, to know a mere empty husk from a real seed: this knowledge is most useful in regard to flower seeds, for of the more select plants a considerable amount of indifferent seeds are sold. Only lately we had a packet of So-and-So's "superb *Cineraria* seed" sent us,

price 5s., and on examining it with a glass scarcely a single *Cineraria* seed could be discerned in the packet. It was returned, and a better article was at once forwarded, with the assurance that the first packet was sent as received from the grower, which we do not doubt. A grower who supplied seeds of a certain popular succulent some years ago at a shilling a pod, sent pods containing only empty husks, which were returned, the dealer admitting the "mistake." Last summer we received seeds of a certain "Superb" Broccoli, which produced Charlock principally, showing how carefully "selection" had been conducted. Such cases, however, it is but fair to say, are exceptional, for seedsmen do their best generally to supply the best article procurable. The only way in which a sower can select his seeds, in the majority of cases, is to thin out his seed-beds early to the best plants. The strongest plants will soon show themselves, and in garden culture much is gained by selection at the thinning period. In the case of early Turnips, for example, there is often an extraordinary difference in the seedlings as regards vigour, and if the strongest are left they will be fit for use a week or more earlier than the others would have been. It is the same with all the Brassica tribe, with Carrots, and notably with Seakale, the seed of which varies much in size; in fact, it is quite easy to select it before sowing, and it is often done. Kidney Beans should always be selected, as there is no occasion for sowing them thicker than the plants are desired to be. The seeds of different varieties vary much in size, but it is easy to tell the good seeds from the bad in any particular sort, and both the small and deformed should be put aside. The same advice applies to Broad Beans—plant the largest. It is well known that improved varieties of such esculents, as often as otherwise, originate in careful selection, which should be followed up annually, or the strain may degenerate the same way in which it came. While inculcating the importance, however, of selecting the largest seeds, or of thinning to the best plants, let it not be forgotten that generous culture, as has been already stated, will to a great extent compensate for want of vigour in the seedling. A poor or ungenial soil in the seed-bed will spoil all. The seed itself is only intended to afford the young plant temporary sustenance, and unless the young rootlets can find other means of support readily as soon as they begin to push, the plant will be simply starved. This is frequently illustrated in the seed-bed, particularly if thickly sown, the plants at the outside of the bed always being by far the strongest, for the reason that they have access to a more abundant supply of food than those in the centre, whose roots interlace each other so thickly that they soon exhaust the thin stratum of soil in which they grow. Plants sown in drills hardly suffer in this way, their roots having room to extend laterally. It is an excellent practice to sow all seeds which have to be transplanted in drills. It takes but little more room, and is more than compensated for by the vigour of the plants and the time saved in thinning. Broccoli, Cauliflower, Lettuce, Stocks, and Asters, &c., that sometimes cannot be transplanted at the proper time, are frequently injured by being left in the seed-bed too long, for they begin to suffer almost as soon as they have passed the seed-leaf stage. Another question of some practical importance regarding the qualities of seeds, is the belief very commonly entertained that new seeds, as in the case of the Melon, Cucumber, Gourd, Tomato, and other annuals grown for their fruit are not fruitful, the common notion being that they run too much to bine. Many practitioners, if they cannot procure seed old enough, will carry the new in their pockets for weeks, or lay it on a mantel-piece above a fire in order to weaken its vitality, in the belief that they thereby ensure a better crop of fruit. Now the only effect such treatment of the seed can produce is debility, more or less, in the plant, and the question is, is a weak plant likely to produce either more or better fruit than a strong one? We think not. We have tried old and new seed separately, in the culture of the Melon, and our constant experience has been that the old seed produced fruit a little earlier perhaps, but considerably less of it, while new seed produced plants which, if allowed to extend themselves, bore both freely and abundantly, and often a second and third crop, which old seed has, as a rule, not the strength to do. For these reasons we have for a long time preferred new seed to old, and have never had occasion to alter our opinion in the matter. It is highly

important to get vigorous seedlings, and if a gross habit be suspected in any variety, the cultivator has ways and means of checking it without staking his chances upon old and perhaps worthless seeds. It has been already hinted how weak seedlings can be invigorated by generous treatment, and so over-luxuriance may be checked by the opposite treatment. The strongest-growing Cucumber or Melon may be absolutely stunted by growing it in a pot, or in a poor soil firmly beaten. Generally speaking, however, the secret of growing Melons is to grow them on the extension system, to give them both root-room and top-room, in order to get a good breadth of wood and foliage, and then to crop heavily.

CHEF.

VIOLETS AND THEIR CULTURE.

Few plants are more appreciated at this season, both by rich and poor, than Violets, and few are, as a rule, more neglected. A few half-starved plants of them may here and there be found in some out-of-the-way corner, where they are often allowed to dwindle and die from want of support. As Violets are found so abundantly in woods and by the sides of hedgerows, few imagine that they require a generous soil, or that they are improved by good cultivation. In preparing a bed for them, the soil can scarcely be made too rich, provided it is open and well drained, and under such conditions there need be no lack as to quantity or quality of bloom. They thrive well on a moderately heavy rich soil; if it happens to be light and gravelly, some stiff material and plenty of manure must be added to it, and if poor and hard clay, it will be benefited by the addition of some sharp, gritty matter, and abundance of rotten manure. Aspect, too, is quite as important as the proper preparation of the ground. Violets require shelter, but not that of a wall. Their natural shelter is a hedge-row, in which they get currents of pure air, which are so essential for keeping down red spider, and for maintaining the foliage in a healthy state. In town gardens, and in gardens surrounded by high walls, they are seldom healthy. They grow well on the north or north-east side of a Hornbeam hedge, provided it is somewhat naked at bottom, so as to allow the sun to shine on their leaves early in spring, and also afford a partial shade in summer. When, however, the soil is deep and rich, they will bear a considerable amount of sunshine without injury. It is well to have a few plants of them in different positions, so as to ensure a succession of bloom. On south borders they dwindle and die; but a few roots on sunny banks will produce some early pickings. Violets of all kinds are easily increased by means of cuttings made from stout short runners, rejecting all that are wiry and hard, and they should not be taken from plants that have grown in pots or under glass. The cuttings should be taken off the first week in April, if they are intended to bloom next year, put under hand-lights on a shady border, and kept close until they have begun to grow, when the lights may be tilted a little, gradually increasing the space, until at last they may be wholly dispensed with. By September they will be ready for transplanting, when they may be planted in beds 4 ft. wide, three rows in a bed, 1 ft. apart. This will afford space to hoe between the rows while they are growing. They will soon spread and fill the beds; but they must not be allowed to remain more than two, or, at the most, three years in the same place, or the flowers will become small and short-stemmed. If they are permitted to remain more than two years on the same piece of ground, they must either receive liberal top-dressings of rotten manure, or copious applications of manure-water. Another mode of propagation, which is, perhaps, attended with the least trouble, is as soon as they have done blooming, to get a few large plants and tear them into as many pieces as possible with a little bit of root attached to each. This is how I always propagate my Violets, and those I had planted last April covered the ground long before autumn, and since October, when the weather has been mild, they have afforded ample pickings. Little pieces without roots may be placed under hand-lights and treated the same as cuttings. Of varieties perhaps the Russian is the most popular. In warm sheltered corners it will begin to bloom early and continue to furnish flowers even during severe weather; the Czar, which is an improvement on the Russian, has flowers of a deep blue colour, of great substance, and supported on stout foot-stalks, 8 or 9 in. long. I re-plant a portion of this variety every spring. The newly-planted beds begin to bloom the first week in October, and we have a succession of flowers all the winter. I at one time grew the Queen, a white variety, which I have long since discarded on account of paucity of bloom. For general purposes there is no better white than the single hedgerow kind, which improves very much under cultivation.

R.

NOTES OF THE WEEK.

— THE collections of Camellias and forced Hyacinths in Messrs. Veitch's nursery at Chelsea are at present well worth inspection. Orchids, too, are just now very attractive, numerous beautiful forms of *Dendrobium Wardianum*, and *D. crassinode* being in full flower. The rare and distinct *Phalaenopsis Veitchii* is likewise bearing a spike of lovely rosy lilac blossoms, the three-lobed lip being of a bright rosy crimson tint, set off by a golden crimson-spotted crest. The leaves, which resemble those of *P. amabilis*, are faintly marbled with grey.

— *CYPRIPEDIUM SPECTABILE* and *C. (acule)* humile, both natives of North American woods and marshes, are now flowering freely in Mr. Bull's nursery at Chelsea, the former having white petaloid rosy-lipped flowers, and the latter purplish blooms. Both species, though perfectly hardy, are found to bear forcing well, and their flowers are fresher and even more interesting indoors than in the open border.

— MR. BARR'S bulb and hardy plant grounds at Tooting are now beginning to be interesting. During the past week several distinct varieties of *Narcissus Pseudo-Narcissus* have opened their golden flowers; *Scillas*, *Primulas*, *Hepaticas*, *Iris reticulata*, and many new and rare species and varieties of *Crocus* are also in bloom. The beautiful rich purple *Sisyrinchium grandiflorum* is showing colour, and a bed of *Cyclamens*, including *C. vernum* and *C. Atkinsii*, is a mass of magenta, purple, and white flowers, and beautiful fresh-looking leaves, marbled with grey. These are quite as interesting as the Persian kinds under glass, and, being perfectly hardy and of easy culture, deserve a place in every garden.

— As it appears that seeds of common Chicory or Barbe de Capucin are often sold for those of Witloof, the two being asserted to be one and the same thing, perhaps the following account of the Barbe de Capucin and Witloof, taken from the last issue of the "Flore des Serres," may be of service:—"Every one knows Barbe de Capucin, the common salad of the Paris markets, and which is produced by common Chicory. In the latter, the roots are slender and not thicker, as a rule, than a blacklead pencil, terminated by long, narrow, white leaves, 8 in. or more in length. In the Witloof, on the contrary, the root is short and thick, and bears a mass of erect, broad, thick, imbricated leaves, forming a small elongated solid heart, which reminds one of the heart of a Cos Lettuce. Except in the mere fact of being blanched, the Barbe de Capucin and Witloof are in all points the opposite of each other; length and slenderness on the one hand, and shortness and bulk on the other, they present to us the two extremes of the series of blanched products which can be produced by the Wild Chicory."

— THE following history and mode of culture of the fine plant of *Phalaenopsis Schilleriana*, which was exhibited by Mr. Bass, at South Kensington, the other day, and to which a Davis medal was recommended to be given, have been forwarded to us by Mr. Bennett, Mr. Bass's gardener at Rangemore. The plant, he says, was sent from India about three years ago by Mr. Bass's daughter, a lady who takes much interest in horticulture, along with a collection of other Orchids. They were badly packed, so much so that out of twenty-seven *Phalaenopsis* only six arrived alive. The one in question had one leaf, about 3 in. long, quite shrivelled up, and two roots broken off. Immediately upon unpacking, they were hung up on the back wall of a north house, some garden mats being put between them and the wall. These, from being regularly syringed, kept the plants moist. Several blocks of Mahogany having been sent over with them, the *Phalaenopsis* was placed on one; and, as it began to root after being on the back wall for six weeks, the end of the block was put in an 11-inch pot, filling up the pot and making the block fast in it with crocks and some lumps of fibry peat, the top of the pot and the whole of the block being covered with live Sphagnum. The first season the plant sent up a weak flower-spike; the second year the roots made great progress, running down the block and all among the crocks and peat, and the plant made two leaves 13 in. long and 5 in. wide, and in the spring threw up two flower-spikes, bearing between them 100 flowers. The peat was then, as far as possible without disturbing the roots, picked out and fresh material added, and last season the plant made two more leaves 1 ft. long and 5 in. wide each, and showed two more spikes of bloom, but, owing to the leaves not being quite so long this season as last, only one spike was left. The present spike is 5 ft. long and 3 ft. across, and the plant measured, including the spike, 6 ft. 2 in. high. There are nearly eighty flowers on the spike. The block stands about 15 in. out of the pot, the plant being on the extreme end of it. The temperature has been, during the autumn and winter months, from 60° to 65° at night, with a rise of 5° by day, the summer temperature from 70° to 75° at night, with a rise by day, and plenty of moisture.

THE FLOWER GARDEN.

WHITE-HOOPED PETTICOAT NARCISSUS.

(N. MONOPHYLLUS.)

This is one of the most beautiful of Daffodils, and one which would soon become popular were it a little more easy of culture than it is. Mr. Barr has just bloomed it in a cool frame in his bulb grounds at Tooting, and from flowers furnished by

Narcissus monophyllus.

him the accompanying sketch has been made, but no wood-cut illustration can do justice to the crystalline whiteness, the spotless purity of its flowers, which, like those of many of its allies, preserve their beauty long after they have been cut and placed in fresh water. Imported bulbs of it flowered at Kew in January, 1870, and from these the figure of it in the "Botanical Magazine" was prepared. Mr. Barr's plants differ from the Kew specimens in having the smaller and more elegant chalice-shaped flowers borne on much longer rush-like scapes, and in the leaves being much longer and more slender,

but all the figures and specimens of it which I have seen go to prove that this plant, like its yellow-flowered allies, is a very variable one. Mr. Baker makes it a variety of the common *N. Bulbocodium*, but others think it deserving of specific honours, although the distinctive characters, such as the single leaf and broader perianth segments, are too variable to be relied on. Bulbs of this plant, gathered by Mr. Munby in Algiers, and placed in his herbarium, were found by him to still retain their vitality, and, after a lapse of twenty-two years, upon being potted and placed in a greenhouse temperature, they grew freely. This plant has evidently been known to English cultivators for over two centuries, and it is not a little singular to find that the old authors who describe and figure the White-hooped Petticoat Narcissus, make no allusion to its being more difficult of culture than its allies. "This beautiful little gem," says Mr. Munby, "seems to be rebellious to all the modes of cultivation which I have been able to employ. Hot-bed, greenhouse, open air—all seem alike to fail. I saw last year, at Messrs. Backhouse's nurseries at York, 150 potsful of it plunged in ashes, each containing one bulb, and amongst the whole I perceived only a solitary leaf. Messrs. Barr & Sugden have, until lately, been equally unsuccessful. Mr. Tyerman, of Tregony, has informed me that he has succeeded in forcing some bulbs to grow by stripping off all their outer coats. I myself have potsful of them, from two to four years planted: I look at them from time to time, and find that nearly all are alive, but they do not grow. Messrs. Barr and Sugden's correspondent in Algeria states that he had himself planted a handful of it in a pot, and placed them in a back yard. Within a fortnight every plant had shot forth leaves, and when I saw them they were 4 in. long. These bulbs had probably nearly all flowered during the previous three months. What I wish to infer from this experiment is, that we let them lie too long before planting, and that the coats of the bulbs get hardened by exposure to the air to such a degree that the hair-like roots have not power to penetrate them. Seeds would, no doubt, grow, and I endeavoured to procure some last spring, but the mice were so fond of them that they ate them, capsule and all, before they were ripe. Many of the Algerian bulbs are so encased in the indurated soil during summer that no air can penetrate to them, and the first autumnal rains gradually soften the soil, which being heated by the summer's sun, causes them to shoot out into flower in two or three days after. This Narcissus ought to be quite hardy in England, for it grows naturally in Algeria, at great elevations, and in situations where frosts in winter are both frequent and severe. Near the coast it begins to flower in December, and in the interior it flowers as late as April." Since Mr. Munby wrote the above the seeds referred to have been obtained and are found to germinate readily sown in a cool frame as soon as they are received, but up to the present time, I believe, none of these home-raised seedlings have bloomed. Perhaps Mr. Maw, Mr. Elwes, the Rev. Harpur Crewe, or other cultivators of Narcissi can tell us something more of its history during this its flowering season.

Parkinson, in his oft-quoted "Paradisus," p. 106, says that the White-hooped Petticoat Narcissus, or Pseudo-Narcissus *junifolius* flore-albo, as he calls it, hath long and very green leaves, "among which riseth up a short stalk, seldom half a foot, bearing at the top, out of a skinnish husk, one small white flower, sometimes inclining to a pale colour, having six small and short leaves (segments) standing about the middle of the trunk, which is long and much wider at the top than at the bottom; the small outer leaves or wings are a little tending to green, and the trunk (as I said) is white or whitish, with the brims a little uneven." This plant is figured and described in "Gerard's Herbal," p. 34, fig. 5. Mrs. Loudon asserts in her "Bulbous Plants" that "it is a native of Biscay, and that it is found in great abundance among the mountain passes of the Pyrenees."

This Narcissus is known under various names; it is figured and described in the "Revue Horticole," 1874, p. 329, under that of *N. Clusii*, and a form bearing smaller creamy-white flowers, with a brownish heel to the floral segments, is said to be in cultivation in the Jardin des Plantes under the name of *N. Graellsii*. *N. cantabricus* is one of its oldest names, but *N. monophyllus* is that most generally adopted. F. W. B.

SOWING SEEDS OF ALPINE AND HERBACEOUS PLANTS.

As about the first or second week in March the all-important operation of seed sowing should be attended to, a few hints on this subject may not be inappropriate at the present time. I am, of course, presuming that cultivators of herbaceous or Alpine plants are fully aware of the necessity of a watchful eye over all plants that are not endowed with root-rambling propensities during the summer and autumn, with a view to collect, dry, or store away their seeds. If they have not been watchful, my advice is not to allow another summer to pass by without carrying this process into effect. The simplest plan is to arrange the seeds in a series of garden saucers of various sizes, on which should be written the names of the seeds, and place them in a dry room or a sunny window, commencing on a wet day; when no out-door work can be done, to clean them thoroughly; then put them away in ordinary seed papers, on which should be legibly written the name and the year in which they are collected. The value of this will be readily understood, when I say that in the best managed herbaceous border not a summer will pass without blanks being left, owing to such causes as a very dry season, a very wet season, an ants' nest, a family gathering of wire-worms or black grubs, so great a pest in some soils. In addition there are many good border plants that are biennial, and others which, though not absolutely biennial, rarely flower a second time with the same vigour as the first. All these sources of possible disappointment give to the practice of collecting seeds as much importance and value, as is the reserve corps to a good army. Possibly they may not be required for two, three, or even half-a-dozen years, but if stored away in a dry and moderately equable temperature, they will keep in good condition for that time. The best position is in a rough canvas bag suspended from the ceiling in a dry room. The next point is the process of sowing. My advice is to sow in pots or pans, varying in size according to the quantity of seed; let these be clean and well drained with potsherds or rough ashes. As to soil, the great bulk of seeds will do well in a mixture of sandy loam and leaf-soil, with the addition of a little peat where available; nothing, however, can be better than the "pot emptyings" of those plants which have ornamented the greenhouse during the autumn months, and which should have been placed in a bin in the potting-shed by themselves, with the addition of a fifth part of leaf-soil well sifted, 2 in. of rough material being placed in the bottom to protect the drainage; above that, press the fine soil firmly down, filling the pot to within $\frac{1}{2}$ in. of the brim; and on this surface the seeds should be sown. As regards covering, a very slight amount of soil will be necessary, provided the plants are to be placed under the protection of glass; but this top-soil should be well incorporated with sharp silver sand, in order that the water from a fine-sorted pot may be absorbed at once over the whole surface. After covering, press the soil firmly down with the bottom of a clean flower-pot, and labelling will complete the operation. For all Alpine and herbaceous plants I prefer a cold frame. The more perfect the glazing (so as to avoid drip) the better. The progress will be slower than when heat is used, but it will prove surer. Some recommend that no water should be given for a few days, but I find a great advantage from watering with a fine rose before removal from the potting-shed; by this means the surface becomes set, and, if by chance and—by no means an unlikely one in removing them—a pot be upset, its contents will remain intact, thereby preventing the loss of a valuable sowing of seeds. Having selected the frame, which should be in a fairly open sunny situation, clear of the drip of trees, a good dressing of quicklime and soot should be applied, or perhaps better still, a good dose of lime-water should be given, so as to destroy the worms, which play sad havoc when they get into a seed-pot; generally they are supposed to eat the roots, but virtually they disturb and disintegrate the soil, destroying its virtue for the support and nutrition of the young plantlets. In arranging them in the frame, be careful to set the pots and pans, especially the latter, perfectly level, so that the water may settle evenly through the whole mass. Keep the frame close, and give no water for a week, or even two, if the weather be dull. JAS. C. NIVEN.

PLANTS SUITABLE FOR THE WILD GARDEN.

Wild gardening has become a fashion, and a very good fashion it is; many are thus led to appreciate and enjoy the common plants in the country everywhere surrounding them which would otherwise pass unheeded. There is no plant not exquisitely beautiful, although the beauty of some is more striking, more demonstrative than that of others, but to suppose that we can improve the natural beauty of plants by the tying-in, or tying-out, or cutting, or confining, is a mistake. We cannot make a plant more beautiful, or so beautiful as if left to grow in its own natural way, not all leaf or all flower, but enough of each as Nature intended, and this is the great secret of the perpetual charm of a wild garden. Each plant grows as Nature intended; you apparently get rid of the artificial, there is perfect freedom, and you look and wonder at the forms of grace and beauty, the charms of colour and smell in common things, even in their very decay, for in them we know there is the resurrection and the life again. There is also a pleasant feeling that the plants are fulfilling their destiny, that they are really enjoying their life—not too much heat or too little, not too much water or too little. Nature is head gardener, and exercises that vigilant and healthful care which makes the very plants rejoice, and the heart of every rightly disposed man or woman to rejoice also in looking at them. What a wild garden ought to be all your thoughtful readers imbued with correct taste now pretty well know. It is really the refinement of art—disorderly order—the greatest taste and skill being exercised in concealing art, or showing that the hand of man is in any way interfering with those laws in reference to the plants which, proceeding from the Great Creator, work his will.

Amidst the luxuriance of Furze and Heath, of Ferns and Brooms, of Holly, Brambles, and wild Clematis, of Bryony and wild Roses (the delicate scent of which latter tribe of plants cannot be excelled), of Ivy and Periwinkles, of Foxgloves, Primroses, and Honeysuckles, let me suggest one plant to your readers which, in a wild garden, for summer and winter effect is invaluable—I allude to the great pendulous Sedge, *Carex pendula*; its long narrow leaves form the most striking contrast to all plants of the Fern tribe, and, as far as my experience goes, I have scarcely seen the plant used in a wild garden. It is easily procured, it is evergreen, its leaves are in well-grown plants about 3 ft. long, and its flower-stems are quite 5 ft. and sometimes 6 ft. high, but its great recommendation is that it seeds so abundantly; once obtain a few plants, the whole of the wild garden in a few years may be covered with it, of all sizes, coming up naturally in all sorts of odd places. It grows in any soil; the more moist and better the soil the larger the growth. In good situations the tufts increase to a large size; 3 ft. in diameter is not uncommon, but the smaller tufts, amidst rocks and Brambles and Ferns, from their brilliant green, produce possibly the best effect. Those who have not this Sedge I strongly recommend to obtain it; it will add a new charm to their wild garden.

There is another plant common enough, but not so much seen in wild gardens as it should be, viz., the Virginian Poke Weed (*Phytolacca decandra*). Its long, graceful, reed-like stems are 7 ft. high, and bear pinkish flowers and Blackberry-like fruit; its foliage is abundant and good in colour. The great ease with which, by the aid of birds, it becomes self-sown—springing up in all kinds of odd out-of-the-way places where you would scarcely think of planting it—renders it a most desirable plant to aid the illusion of unkempt wildness.

There is another dwarf plant of not many years' introduction, which, for spring effect in a wild garden, mixed with the common yellow Primrose, is admirable. I allude to the Forget-me-not, called *Myosotis disitiflora*; this becomes quite wild. Only let alone, in a year or two, from only a few plants you may have thousands springing up in the grass or rude walks, under rocks, at the bottoms of trees—anywhere and everywhere, with their lovely pale blue flowers.

There is another plant common enough, but one which no wild garden should be without if there is only space, and that is the Cow Parsnip (*Heracleum giganteum*). In a favourable situation it will send up stems 10 ft. high, with leaves 3 ft. in length. It is a grand plant, requiring not the slightest care in cultivation, and once planted in a wild garden and allowed to seed, there will be some difficulty in getting it out of the garden even if desired; it will grow in the most unlooked-for spots, the seeds being carried by the wind. I have named now four plants which no wild garden should be without. Strikingly different in every feature, they possess one common advantage—they are of a kind not in any way likely to interfere with the effect of the ordinary well-known British wild plants. One effect a wild garden should have, without which it is most imperfect—it should possess the charm of intricacy, it should be so constructed that the mind may imagine more than is seen; the mystery and fulness of plant growth should never be fully revealed, except

diligently sought for; possibly a well-constructed thicket, with rocks and a small stream of running water, may be made to represent the highest form of art of which a wild garden is capable, and such a garden can never tire. Winter or spring, autumn or summer, it will always be beautiful, and always present new sources of interest and delight.—“Gardener’s Chronicle.” [It is most important to plant such rampant subjects as the giant Cow Parsnip in isolated spots, as it becomes a great nuisance when it spreads about and destroys all the more delicate plants near it. A few plants of it on an island or in some place where they cannot injure other plants by spreading are best. They are, moreover, far from pleasing in appearance when they become the predominant feature. They are seen to greatest advantage in small numbers and in groups in contrast with other plants.]

THE DIFFERENT VARIETIES OF SALPIGLOSSIS.

These now occupy a leading position amongst our showiest hardy annuals. Among them are some new hybrids, remarkable for the size of their flowers and the rich beauty of their colours, which range from a creamy white up to glossy crimson maroon, through many intermediate tints. Some of the blossoms are finely marbled and pencilled, generally on cream, primrose, buff, and yellow grounds. We are indebted to Chili for the original forms of the Salpiglossis. Then followed what is customary with plants of this character raised from seed

Salpiglossis hybrid.

—the progeny gave different types, and led to improved varieties being named and put in circulation, and some of these can be had in separate colours. The new hybrids, as they are termed, may be said to sum up all the recent improvements, and clumps or masses of these in varied colours have a more effective appearance than either a few, or a large number of plants of any one variety. They flower with great profusion, and as the plants branch freely from the main stems, a continuity of bloom is thus secured. A bed of these Salpiglossis in full bloom is scarcely surpassed by any other hardy annual. Though generally classed among the half-hardy annuals, the seed of the Salpiglossis may be sown in the open ground, provided the soil be light and somewhat sandy, and the position warm. Every year Mr. A. F. Barron, the superintendent of the Royal Horticultural Society’s Gardens, sows a large bed in this way, in lines about 18 in. apart, and, as a matter of course, somewhat thinly. The plants come into flower in July, and continue almost to the end of the summer. If wanted in flower at an earlier date, then seed can be sown with the half-hardy annuals, and the plants transplanted to the open ground, and protected by hand-lights, or some such contrivance. No collection of annuals could possibly be complete without the fine showy forms of the new hybrid Salpiglossis. I have sometimes wondered, if the seed were sown in August, whether the plants could be grown on and flowered in pots, in the same way as *Schizanthus pinnatus*, in March or April. If they can be so treated, they would be very beautiful subjects in the spring time; at any rate, plants treated in this way would flower earlier in the open ground than from spring-sown seed; but the plants would, as a matter of course, need to be wintered in cold frames, or to be otherwise protected.

Quo.

FOXGLOVES IN MIXED BORDERS.

THESE are eminently fitted not only to adorn our wastes and wilds, but also our flower borders, where their stately growth and beautiful flowers render them always welcome. In mixed shrubberies and semi-wild places, when once established, they take care of themselves, and annually produce a gorgeous display. Although Foxgloves will grow and flower even in the poorest soils, they will repay more generous treatment, a fact which I have had ample means of proving; for, having a large extent of newly-planted shrubbery that had been well prepared by deep trenching, we planted in the intermediate spaces any hardy flowers that were available in order to give additional interest until the shrubs and Conifers required the space; and strikingly conspicuous were the Foxgloves, whose spikes of bloom not only averaged from 8 ft. to 10 ft. in height, but branched out into quite a column of spikes, thus securing a long succession of flower, and materially prolonging the display. They were indeed as different in aspect from the single stems of starved plants that one generally sees as could possibly be imagined. As the seed is very small, in commencing the cultivation of Foxgloves, it is advisable to sow it in a bed or box of very fine soil, and to prick out the seedlings into nursery beds as soon as they are large enough to handle. They will be in good condition for removal to their permanent quarters by the autumn of the first year or the spring of the following, and if the seed has been procured from a good collection, great variety may be expected. When once established they increase enormously from self-sown seed; but if fine spikes are desired, they must be thinned out and treated as has just been stated, or they will soon deteriorate. By selecting, however, the finest and best marked flowers for seed-bearers, and by removing spikes of inferior kinds before the seed is ripe, their quality will yearly improve. Many comparatively waste places may be greatly improved in appearance by means of such hardy flowers as these—flowers which everybody appreciates. J. Groor.

Henham.

New Violets.—When I first saw that excellent Violet, Lee’s *Victoria Regina*, a year or two ago, I had an impression that in size, colour, and fragrance, it would never be surpassed. I have now before me, however, fresh flowers of Mr. Lee’s new seedling Violet called *Prince Albert*, which is in every way superior even to *Victoria Regina*, the flowers being fully 1 in. in diameter, and of a rich dark violet-purple colour, set off by orange-coloured anthers. *Victoria Regina* is at present preferred to all other Violets in Covent Garden Market, but, when better known, this new seedling will, I imagine, supersede it.—B.

Best Early Flowering Hardy Plants.—The greatest favourites, amongst many others, at present in bloom in my garden are the following:—*Iris reticulata*, with its purple and golden flowers; *Saxifraga Bursericana*, smothered with open white flowers the size of a sixpence, and one of the most effective of the group to which it belongs; also *S. oppositifolia* and its white variety; *Primula purpurea* is now well in bloom, but it is more lilac than purple; the beautiful little *Crocus Aucheri*, of a fine orange colour, is certainly one of the best of its class. *Sisyrinchium grandiflorum* and the white variety are in blossom, and will be followed by *S. odoratissimum*, white striped with brown; and last, but not least, that most beautiful of all spring flowers, *Anemone blanda*, is at present in great beauty.—OXON.

Roses in the Suburbs.—Let the plot of ground, or such of it as is set apart for Roses, be trenched and manured by somebody who knows how to do it. If the soil be a hungry one—gravelly or sandy, or mere brick rubbish—dig into it as much adhesive loam as can be got. If you can’t get good loam send for clay, never mind how stiff it is; it is the natural food of the Dog Rose, and only wants the admixture of a little manure. If there be a spare corner in which to heap up the clay for a month or two, sprinkle it heavily with sand, and occasionally turn it over before digging it in; under this treatment it will be rendered more permeable to the rootlets of the plants. If the garden be in a sour, black condition, sweeten it by a good sprinkling with lime, and if a little salt be added it will be better still. Lime and salt will destroy fungoid nuisances and crawling insects which plague the possessors of small gardens. Avoid the drip of trees and sloping banks exposed to the south-west for Rose situations. Draughty corners, angled down into which the dust and smoke have a wretched habit of descending, are obviously bad; the more exposed to the open air and sun the better for the Roses. Let the ground be turned over during the spring; don’t be in a hurry to plant; it is too late usefully to plant Roses in the neighbourhood of London; wait until the end of October. During the summer select the Roses at some good Rose-grower’s, and limit

them to a selection from the following list, which have borne the smoke and bad-soil tests; they are all strong growers, and have good constitutions:—Abel Grand, Achille Gouand, Antoine Mouton, Alfred Colomb, Anna Alexieff, Bessie Johnson, Baron Bonstettin, Baronne de Maynard, Baroness Rothschild, Boule de Neige, Captain Christy, Charles Lefebvre, Comtesse d'Oxford, Duke of Edinburgh, Duchesse de Morny, Elizabeth Vignerot, Etienne Levet, Général Jacqueminot, John Hopper, Jules Margottin, La France, Madame Victor Verdier, Madame Boll, Madame de Cambacères, Madame George Schwartz, Maréchal Vaillant, Pierre Seletzki, Paul Neron, Prince Camille de Rohan, Princess Louis Victoria, Souvenir de Poiteau, Victor Verdier, Aimée Vibert, and Gloire de Dijon.—"Gardeners' Magazine."

Daphne rupestris.—This is a real Alpine gem, surpassing the well-known trailing sweet-scented *Daphne Cneorum*, both in beauty and fragrance. It has erect shoots, and forms dense compact tufts, 2 in. high and a foot or more across, covered with a mass of bloom which sometimes almost eclipses the plant. Its colour is a soft shaded pink or rose, and its flowers are individually larger and more waxy than those of *D. Cneorum*, but forming clustered heads in the same way. It is essentially a rock-plant, growing wild in fissures of limestone in peaty loam. It is perfectly hardy, and of easy culture.—J. BACKHOUSE, York.

Verbena venosa from Seed.—This is much hardier than ordinary *Verbenas*, and it is neither so liable to be injured by mildew nor to be damaged by bad weather. Being of a branching and wide-spreading habit, it has a grand effect in large patches, bound round with some contrasting colour; *Mangles*' variegated *Geranium* and it associate beautifully together. It is easily raised from seed, which should be sown four months before the plants are wanted, as the seeds frequently take long to germinate. The seeds, which are rather small, should be saturated in water for twenty-four hours before being sown. Fill 6-in. pots, well drained, with loam, sand, and leaf-soil; strew the seed thinly over the surface, but do not cover it over, and water it through a fine rose to settle it in the soil. The pot should then be plunged in a bottom-heat of 75°, and the soil should be constantly kept in a moist state. As the seedlings come up and form four leaves, they should be lifted out carefully, to make room for those which may follow, and the young plants should be planted in pans or boxes about 2 in. apart in much the same kind of mixture as that in which the seed was sown. If they are then placed in a heat of 60° they will shoot up rapidly, and if stock be short, the tops may be taken off and put in as cuttings. When once a sufficiency of this plant has been raised, it may be retained without annually having recourse to seed-sowing. If the roots be covered over in the lower beds with a few inches of leaves or manure in autumn, they will winter safely; and, if lifted about the beginning of February, and started in a heat of 60°, plenty of cuttings will soon be produced. In cases in which it is necessary to lift the roots in autumn, they may be placed at once in the boxes in which they are to be started, and kept in a cool place until the time arrives for putting them in heat. In herbaceous borders, the roots may be allowed to remain for years, but they should be protected throughout the winter, or they may be injured should the frost be severe.—J. MUIR.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

The Golden Foxglove.—Can any of your readers inform me where I am likely to obtain plants of the Golden Foxglove (*Gerardia quercifolia*)? I am informed that it grows on the Catskill Mountains, near New York, and that it is known as the American Golden Foxglove—R. D.

Agave Utahensis.—This is a really hardy Aloe from a high mountain region. It forms a very distinct and most interesting rock-plant, the colour of which is silvery-glaucous. It should be planted in a sheltered place on rock-work in full sunshine, and where the roots can penetrate into moist rich soil, limestone being preferred.—M.

Hepatica Barlowii and other kinds.—This beautiful variety of the *Anemone Hepatica*, although not new, is far from common. All who care for the *Hepatica* will do well to add it to their collections, as the flowers, being purplish-maroon, are distinct in colour, and it has a robust habit of growth. The flowers are large, and good-sized plants, in full bloom, have a charming appearance. My collection of *Hepaticas* now includes single and double red, single and double blue, single white, single marve, angulosa, and Barlowii. Is there a double white kind in existence?—A. D.

Effective Spring Flowers.—I have often been astonished to hear people who have gardens ask the name of the pretty Siberian Squill when they have seen it in bloom here. Why it is not as well known and as commonly grown as the Snowdrop is a marvel; for its flowers are of a lovely blue, a colour by no means common in gardens at the end of February. If anyone wish to secure a startling effect on a border early in spring, let him plant in good-sized patches Double Snowdrops, Siberian Squills, Cloth of Gold Crocus and Double Red *Hepaticas*; all of these will produce lovely masses of colour at the same time.—A. D.

THE LIBRARY.

LIVINGSTONE'S LAST JOURNEYS.

THE interest of this book depends very little on its botanical contents, and yet few men must have seen more striking aspects of vegetation or more of tropical and sub-tropical African vegetation than Dr. Livingstone. The interest, too, of the book is sadly marred, from the fact that the native names are, as a rule, the only ones used in speaking of plants and thus one can rarely get an idea of what is meant respecting the rich and beautiful nature of the country and the scenery here and there referred to. For instance, on p. 255, vol. i., we read as follows, in a letter to Lord Clarendon, concerning the shores of Lake Liemba:—

"On the second April last we reached the brim of the cup-like cavity in which the lake reposes. The descent is 2000 ft., and the still surface of the water is upwards of 2500 ft. above the level of the sea. The sides of the hollow are very steep, and sometimes the rocks run the whole 2000 ft. sheer down to the water. Nowhere is there three miles of level land from the foot of the cliffs to the shore; but tops, sides, and bottoms are covered with well-grown wood and grass, except where the bare rocks protrude. The scenery is extremely beautiful. The Aeasy, a stream of 15 yards broad and high-deep, came down along our precipitous path and formed cascades by leaping 300 ft. at a time. These, with the bright red of the clay schists among the greenwood trees, made the dullest of my attendants pause and remark with wonder. Antelopes, buffaloes, and elephants abound on the steep slopes, and hippopotami, crocodiles, and fish swarm in the water. The elephants sometimes eat the crops of the villagers, and flap their big ears just outside the village stockades. One got out of our way on to a level spot and then stood and roared at us. The first village we came to on the banks of the lake had a grove of Palm oil and other trees around it. This Palm tree was not the dwarf species seen on Lake Nyassa. A cluster of the fruit passed the door of my hut, which required two men to carry it."

Allusions to trees or plants are usually no more instructive to the botanist than the following:—

"One fine straight tree in the hollows seemed a species of Fig; its fruit was just forming, but it was too high for me to ascertain its species. The natives don't eat the fruit, but they eat the large grubs which come out of it. The leaves were 15 in. long by 5 in. broad; they call it Unguengo."

"Among the vegetable products of this region (near Lake Moero) that which interested me most was a sort of Potato. It does not belong to the Solanaceous but to the Pea family, and its flowers have a delightful fragrance. It is easily propagated by cuttings of the root or stalk. The tuber is oblong, like our Kidney Potato, and when boiled it tastes exactly like the common Potato. When unripe it has a slight degree of bitterness, and it is believed to be wholesome; a piece of the root eaten raw is a good remedy in nausea. It is met with on the uplands alone, and seems incapable of bearing much heat, though I kept some of the roots without earth in a box which was carried in the sun almost daily for six months without destroying their vegetative power."

In extracts of this kind the book abounds, and they are very suggestive of the botanical interest possessed by the great forest plateau of Central Africa.

The Chufa, or Earth Almond.—The Chufa is a perennial, indigenous in the south of Europe, growing in the form of a Rush to the height of about 3 ft., producing small tubers about the size of an ordinary Bean, called by the French, *Souchet Comestible* (Rush Nut). In taste the tubers resemble a delicious Chestnut or Cocoa-nut, and may be eaten raw or cooked. After soaking in water twelve hours, they may be eaten as a sauce. Dr. C. T. Jackson, in the "Journal of the American Department of Agriculture," states:—"When these tubers are beaten to a paste and mixed with water, a remarkable emulsion is formed, which, after straining, resembles milk in appearance. The fat at length rises to the surface and looks like cream, whilst most of the starch subsides to the bottom of the vessel; but enough still remains suspended to give the emulsion the appearance of thin or skim milk. Thus mingled with water, the most nutritive ingredients of this plant may be taken as a drink. It is much used in this manner by the Spaniards, and I have no doubt will be so employed in this country. This emulsion may be sweetened and flavoured so as to make it very agreeable to the taste." They are chiefly used in Spain and other hot European climates for making an orgeat (orchata de Chufas), a delightful and refreshing drink.

AN AFRICAN FOREST. From "Livingstone's Last Journals." (F. Sch. Edition).

THE INDOOR GARDEN.

FUCHSIAS PLANTED OUT AND IN POTS.

AMONG my earliest recollections of Fuchsias was a large old "tree" (I may safely so call it) of exoniensis, planted in a conservatory border. It has, however, long ago disappeared, and the name is well-nigh forgotten; and many others, raised since, have had to give way in like manner to improved varieties; but I still think that for the decoration of large houses, the system then adopted, of planting them in the borders, and either training them as pyramids or standards, had its advantages. Another plan that I have often adopted in treating them as permanent plants was to cut them down to the ground after they had ceased blooming without disturbing the roots, thus making room for Chrysanthemums and other autumn and winter-flowering plants, these again being removed when the Fuchsias commenced growth in spring. With a little thinning and training, dense globular-shaped bushes would be formed that would astonish anyone whose experience had been confined to their culture in pots. But, in addition to the examples I have just mentioned, there are still more effective ways of growing and training Fuchsias. The free-growing kinds may be led up into the roof and trained along the rafters or over arches, where their beautiful pendulous wreaths of flowers would be seen to the best advantage. There are some kinds, such as *Dominiana*, that bloom naturally in winter; others, as *Venus de Medici* and *grandiflora plena*, if pruned back in August, will make a new growth and flower beautifully the greater part of the winter. Unfortunately, although the number of varieties of Fuchsias now in cultivation is legion, those of a really good branching habit are still comparatively scarce. Raisers of new Fuchsias seem to have paid more attention to the improvement of the size, shape, and colour of the flower than the habit of growth of the plant. Looking back to the time when *globosa* was held in high estimation in the flower garden—and many effective beds I have seen of it—the idea naturally presents itself that we ought now to be in possession of a race of dense-habited varieties suitable for mixed borders or for beds. I think Fuchsias have been looked upon too much as greenhouse plants, but, in most places, even the tenderest new varieties may be left in the ground during the winter, provided a cone of ashes or old tan be placed over the crowns after they are cut down and before severe frost sets in. Although I have directed attention to various effective modes of growing and training Fuchsias in large houses where there is room for development, yet the Fuchsia submits very readily to pot culture, and in most places that must still remain the chief way of cultivating it. A few plants placed in heat in February will produce plenty of young shoots that will quickly strike either in a pan of sand and water placed near a fire or hot-water pipe, or they may be dibbled into pots of light sandy soil and plunged in a hot-bed of 75° or 80°. There is a freshness and beauty about young plants when grown in pots that old plants never attain; in fact, for ordinary purposes of decoration (unless very late plants are desired) old plants, if kept in pots at all, should be cut down and converted into bushes. In this way handsome plants full of young vigorous growth, superior in every respect to the old scrubby plants commonly met with, will be formed. I admit the pyramid-shaped plants, with a single stake to support the main stem, regularly clothed from the pot upwards with a dense growth of drooping branches full of flowers, have a more natural and more graceful effect; but in most places there is room for variety, and other forms are undoubtedly admissible, may even be desirable. In the culture of Fuchsias, to have well-grown plants from the time they are fit to be removed from the cutting pot until they are in their blooming pots, they should never be allowed to become pot-bound, moderate shifts being by far the most preferable. If they be not shifted on as soon as the roots are fairly in possession of the new soil, they will experience a check that will throw them into flower, and after that it is almost useless trying to force growth. On the other hand, if they be shifted into pots of too large a size, unequal growth will take place; strong shoots will break away, which will necessitate stopping, and, in all probability, spoil the symmetry of the plants. In

potting, the ball should be transferred from one pot to the other without injuring or disturbing the roots in any way, and the soil should be rammed in moderately firm; young plants should be shifted into pots 1 in. larger, but as the plants get stronger 2 in. will not be found too much, as rougher compost must be used. Fine specimens may be grown in 10 or 12 in. pots, and very handsome pyramids of 3 ft. in height may be had in 8-in. pots. Fuchsias like a rich soil freely drained, consisting of turfy loam, old thoroughly decayed manure or leaf-mould in about equal portions, with a good sprinkling of charcoal dust and sand, and, if at hand, a handful of bone-meal may be added at the last shift. Should they be required to bloom for a long time and continuously, they must be well fed. During the time they are making their growth a moist atmosphere is indispensable, and they will succeed all the better if placed on a damp surface in a house where the night temperature does not fall below 55°. They are often well grown under Vines, the moist atmosphere necessary for their proper development, and the partial shade of the Vine foliage seeming to benefit them materially; bear in mind, however, that where the Vines are closely trained and the foliage becomes dense, the shade will be too much for the Fuchsias. When extra large plants are required for exhibition purposes, it is better to strike the cuttings in August, and grow the young plants steadily on in a warm house during the winter, and by the usual time of spring propagating they will be fine bushy plants 1 ft. or more high, in 48-sized-pots, ready for pushing on with the increasing daylight; and, of course, such plants, under similar management, will never be overtaken by spring-struck cuttings; but it involves more trouble, as they must have a light warm position. When in flower, they should be placed in a cool airy house. A north house will suit them admirably in hot weather, and they will be benefited by having clear liquid manure two or three times a week. I have a partiality for soot-water, the effect being, in my opinion, to bring out more fully the brightness of the colours. I have already said that amongst the numerous varieties of Fuchsias now in cultivation, kinds of good branching habit are comparatively scarce. The list I give below does not contain the newest, but the kinds named will not disappoint any cultivator who may choose to give them a trial.

LIGHT VARIETIES.—*Arabella*, Improved, *Lady Haytesbury*, *Puritani*, *Annie*, *Starlight*, *Guiding Star*, *Conspicua*, and *Vainqueur de Puebla*.

DARK VARIETIES.—*Enoch Arden*, *Father Ignatius*, *Souvenir de Chiswick*, *Pauline*, *Roderick Dhu*, *Avalanche*, *Grand Cross*, and *Universal*.

In addition, I should recommend *Rose of Castile* and *Daniel Lambert* for their early-blooming qualities; also *Sunray* for its beautiful foliage, both exemplified in the flower garden and in the shape of small neat plants in winter. E. HOBDAK.

The Peruvian Trumpet, planted out and in pots.—In the race after novelties many a good old standard plant seems to drop comparatively out of sight and out of favour, for the time at least. Among such must be included the grand old *Brugmansia suaveolens*. It is no disparagement to many plants of more recent introduction that are now popular, that, for strikingly distinct character and general effectiveness as greenhouse ornaments, they come very far short of *Brugmansia suaveolens*, a stately plant, producing, when properly managed, a great profusion of immense white blossoms, sweetly fragrant and very effective. To see the plant in perfection, says Mr. Thomson, in the "Gardener," it is best planted out in the border of a large, airy, and light conservatory. But, being a most greedy and luxuriant subject, its roots must not have access to the feeding ground of more delicate subjects, or it will rob them thoroughly; and, to make it bloom most profusely, it should be limited as regards range of border. Although it is a large-growing plant, it submits with comparative ease to small-pot culture; and it is perhaps never so free in its flowering qualities as when confined to pots ranging from 11 in. to 20 in. in diameter. It can be struck from eyes of ripened wood, just as is practised with Vines in early spring, and grown into free-flowering plants in 6-in. or 8-in. pots in autumn. After the wood is pretty well ripened, it may be spurred back very much like a fruit tree, dried off and stored under a greenhouse stage or in a back shed out of the way till spring, when it may be returned to the greenhouse, watered, and, after it begins to grow

if need be, re-potted. Although in a pot of from 15 to 18 in. in diameter it grows and blooms well for several years without being disturbed; a top-dressing with rotten manure, and an occasional watering with manure or guano-water, induces it to grow freely. It will thus be seen that it is an accommodating plant, well suited to the conditions of many amateur growers; and, when treated with merely ordinary care, few plants will rival it for striking effect and sweetness for many weeks late in summer and autumn. It may be pruned into any shape, and, probably, from the drooping habit of its flowers, it is best grown with a clean stem to any height, according to taste and head-room. It is not by any means particular as to soil, that in which a common Pelargonium will thrive will suit it perfectly. In some nurserymen's catalogues there are enumerated *Brugmansia suaveolens* and *B. arborea*. They are the same plants. Originally it was *Datura arborea*, a name by which, perhaps, it is better known than by any other. There is a semi-double variety called *Knightsii*, also worth growing; and *B. sanguinea*, a flame-coloured variety, is also well worthy of a place where there is room for both varieties.

POTTING HOUSES *versus* POTTING SHEDS.

Few structures about a garden are more useful than that in which plants are potted. About most places there is only a potting shed, which is a storehouse for all kinds of things. Such places, too, are often unfit for the reception of plants, and are uncomfortable for those who are compelled to work in them. Comfort and convenience are points which should be considered in erecting potting houses of all kinds—comfort as regards interior arrangements, and convenience as respects having

Section of a Potting House.

them situated close to where they are most needed. The shed form admits of no choice of a site except that afforded in some out-of-the-way place. A potting house, should, however, be erected like any other glass structure. Of the best form for such a house, the annexed is a sectional representation. It will be seen that there is nothing objectionable in its appearance, and the interior arrangements are all that can be desired. The back part of the roof is supported by a stone wall; the front is provided with hinged lights for ventilation, and there are movable lights on the roof for the same purpose. In the front is fixed the bench for potting on, and there is, as will be seen, ample accommodation underneath it for storing away soil and for keeping it dry. The bench is 3 ft. in width, and the space in the centre is the same width; but this may be increased according to the dimensions of the house. In the back part, a few inches from the floor, is a flow and return 4-in. hot-water pipe, and the shelf above these pipes is for holding the empty flower pots. On the three shelves above this are placed plants which may be brought in to pot, or after they are potted they may remain until another place is prepared for them. In cases of necessity, potting houses of this description may be used as plant houses, the heat being regulated according to circumstances. In such houses potting can be done with comfort, even in the coldest weather; and the advantages possessed by such houses over sheds, in which plants cannot be left with safety for a single night in winter, cannot be over-rated.

J. MITCH.

Sisyrinchium Douglasii.—"Fraxinella" (see p. 234) speaks of the beauty of *Sisyrinchium grandiflorum*: a plant which we had last year from Mr. Van Houtte of *Sisyrinchium Douglasii* is now in bloom; its colour is deeper and still more beautiful than that of *S. grandiflorum*.—GEOFFREY F. WILSON, *Heatherbank, Weybridge Heath.*

CULTURE OF BERRY-BEARING SOLANUMS.

THESE are excellent for table decoration and for other indoor purposes in winter. Seeds of them should be sown in pots or pans, and placed in a temperature of 65° about the middle of this month; and as soon as the plants are large enough to handle they should be pricked into other pans, and ultimately potted singly into pots some 4 in. in diameter, to be planted out in light soil about the last week in May, or early in June, selecting a situation for them fully exposed to the sun. If the weather be dry, they should be well supplied with water, until they have become fairly established; and, as they continue to grow, stop or shorten any of the shoots which may be inclined to unduly develop themselves, in order to secure symmetrical and well-formed plants. Not later than the first week in October they should be carefully lifted and potted, in pots not exceeding 5 in. or 6 in. in diameter. They will then be thickly studded with bright green berries, or, if the summer has been warm, they may be commencing to turn red. Pot them in light and not too rich soil, and as soon as this has been done they should be placed on the north side of a wall, raising the pots on bricks, or setting them on a stage of some sort, to prevent worms from entering the pots, and for some time the plants should be syringed twice or thrice during the day, or until they have become established, which will generally soon be the case, and in the course of a fortnight, more or less according to the state of the weather, they should be placed in a light greenhouse or pit and fully exposed to the sun, abundance of air being admitted whenever the weather is at all favourable. Treated in this way, the bright green berries with which the plants should be thickly studded will quickly become rich coral red, or bright orange and crimson, a condition in which they will remain throughout the winter and spring months.

Soon after the middle of March the berries will begin to shrivel, when the shoots may be cut in, or the plants may be formed into standards, pyramids, or round-headed specimens, as the case may be, placing them in a cold pit, and supplying them with water as required, until about the last week in May. They should then be turned out of their pots, the balls of earth considerably reduced, the long roots cut back, and the plants turned out into a soil and situation similar to those already recommended for seedlings of the current season. These older plants will be more likely to become well furnished with fruit during the second season than the first, and will form better specimens for the decoration of the greenhouse or conservatory during the following winter than young or yearling plants, especially during such cold and wet summers as that of 1875, when yearling plants were so late in flowering that their fruit was not ripe or coloured by Christmas, a season when they are generally most in request. When lifted in October for the purpose of being re-potted, the balls of earth may be so reduced, and the roots cut back to enable them to be potted into pots about 6 in. in diameter, a size most convenient for table and other decorative purposes; but for larger and finer specimens larger pots may, of course, be used. There are few plants, however, which will admit of greater liberties being taken with their roots than Solanums. They, however, like plenty of water when the pots become filled with roots, and any neglect in this respect will be likely to result in a portion at least of the leaves becoming yellow, and falling off.

The best varieties for winter decorations are *S. capsicastrum*, *pseudo-capsicum*, *hybridum*, and *hybridum Hendersoni*. The last named is a fine new variety, bearing an abundance of glossy, orange-coloured, erect, conical-shaped fruit.

Culford Hall, Bury St. Edmunds.

P. GRIEVE.

Lithospermum scandens under glass.—When planted out in a conservatory border, this is a free-growing and excellent climbing plant of easy culture and of considerable beauty. It may be usefully employed for covering bare spaces on walls, pillars, or arches, or for festooning under roofs; it is also especially adapted for draping large hanging baskets, a position in which it flowers freely. Treated as an annual in the open air, it is likewise a desirable plant to have in association with such plants as *Cobra*

scandens, Tropaeolums, Maurandias, and other fast-growing summer climbers, where such plants are in demand for covering walls or scroll-work, or for planting round the edges of rustic beds or baskets. It may be easily raised from seeds sown now in heat, under the same treatment accorded to tender annuals, but I prefer plants raised from cuttings, as I think they have a greater tendency to early flowering. A potful of cuttings that have been well rooted in autumn, and kept in a greenhouse temperature during the winter, will furnish plenty of fresh cuttings, which will quickly strike in heat.—E. H.

Leucophyta Brownii indoors.—In addition to being one of the best of white-foliaged bedding-plants, this may also be turned to good account for winter decoration in rooms or in the conservatory. Old plants of it lifted in autumn, and potted in as small pots as the root can be conveniently got into, or massed together in earthenware pans, if placed in a cold pit, soon establish themselves. Striking effects can often be obtained by arranging masses of dwarf plants, such as *Lycopodiums*, *Coprosmas*, dwarf Ferns, and others, in a deep irregular fringe round groups of taller growing plants, and for such a purpose the *Leucophyta*, owing to its dense habit and peculiar growth, is especially suitable. Early in autumn is the best time for propagating it. In a cold close frame it roots with the greatest certainty, but it must have time, as might be expected, from its wiry habit of growth. Cuttings of it taken in spring from plants previously excited in heat, will also grow, but they do not produce such vigorous, well-grown subjects as when planted in autumn.—E. HORDAY.

Solanum Pseudo-capsicum variegatum.—This is one of the prettiest conservatory or warm greenhouse plants we possess, particularly during the dull winter and early spring months, when flowering subjects are scarce. To have a few grown with good bushy heads, and placed here and there amongst other plants, gives a house a pleasant tone of colour and brightness without any flowers; but when arranged with the berried varieties, red and white *Primulas*, and a few Dutch bulbs intermixed, they show off well, and all have a very pleasing appearance. This variety is best increased by means of cuttings, as it does not come true from seed. Cuttings of the young wood just as it begins to get firm are the best, and will strike in an ordinary frame. When struck, pot them off, and place them in a pit or frame with a little bottom-heat, keeping them close for a few days to enable them to get a firm hold of the fresh soil, admitting air freely on fine days. They should be grown under glass the first season, as cuttings do not grow so freely as seedlings; shift them on as required, using a compost of good rich loam, leaf-mould, and silver sand in equal proportions. In potting, be sure and make the soil firm, and on no account allow them to get too dry at the roots.—W. W., *Eaglehurst*.

Forcing Branches of Hardy Shrubs.—It is necessary that the wood chosen for this purpose should be well ripened and the bloom-buds in an advanced state. *Magnolias* and *Rhododendrons* answer well, and we have been very successful with *Laburnum*, *Hawthorn*, double *Cherry*, and *Ribes sanguineum*. The process is extremely simple:—During January, or early in February cut off good-sized branches, and immerse the bases to a depth of a foot or so in water, in a house that is heated to 60° or 70°, and in from three weeks to a month the bloom will be plentifully produced. I have often practised this plan with success, and I find that the results fully repay for the trouble. The points to be observed are: A properly-heated house; a tank or tub of water—rain-water preferable; and, above all things, good stout branches, well set with bloom buds. I particularly remember one instance:—An old hedge of Maiden's Blush Rose had to be destroyed, and, at the time (February), I had some of the best plants brought in, some with and more without roots; in the third week in April we had Roses by the basketful. The same with the double *Cherry*, *Ribes*, and *Laburnum*. I advise everyone who has sufficient heat to try this simple plan.—“Country.”

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Forced Lilies of the Valley.—I am more than ever convinced that the proper way to grow these charming flowers for forcing is not to turn them out of their pots, but to take care of the foliage, and ripen it well after the plants have bloomed.—N. H. P.

Laurustinus for Winter Flowering.—In accordance with Mr. Simpson's recommendation, I obtained six good plants of *Laurustinus*, and they have been since Christmas one sheet of small pure white flowers. They have been invaluable for bouquets and cutting purposes generally.—H. GIBBS.

The Persian Iris Indoors.—This is truly a little gem, the flowers of which are white, changing to a very pale blue, with a purple maroon-centred blotch on the lip, and a centre stripe of bright orange. It is very sweet-scented. Its height is only 3 in. It is a winter-flowering variety, and the only one that will bear forcing.—R. H. B.

PLATE XI.

NEW NECTARINES.

1, Humboldt; 2, Byron; 3, Lord Napier.

Drawn by H. HYDE.

THE annexed plate contains representations of three new Nectarines, all raised by Mr. Rivers, of Sawbridgeworth, and all acknowledged to be excellent additions to existing varieties of that fruit. They have been carefully drawn from specimens forwarded by Mr. Rivers to THE GARDEN OFFICE.

HUMBOLDT.—This is one of the finest of orange-coloured Nectarines, and one which is a valuable addition to English fruits of high-class character. It belongs to the Pitmaston Orange class, a race which, strange to say, is said to have been raised from the Elruge. The Pitmaston Orange and its descendants are singularly rich in flavour, and when allowed to become fully ripe and partly shrivelled at the stalk, no fruits can be finer than they are. The Humboldt possesses the characteristics of the family in a high degree. In an orchard-house, guarded from the wet, it becomes a sweetmeat. The fruit is above the middle size, and the tree will bear abundantly if allowed to do so; but to obtain fruit of good size and fine flavour, thinning must be rigidly carried out. Its skin is a bright orange, densely mottled with red, and very handsome. The flesh is also a bright orange, and red round the stone. The flowers, like those of the Pine-apple Nectarine, are large and handsome, making the orchard-house very gay during the flowering season.

BYRON.—This Nectarine forms a striking illustration of the variation which occurs in fruits produced from seed. It was raised from the Bowden, a Nectarine not much known or cultivated, and for good reasons, as it hardly deserves notice among the crowd of good Nectarines which we have at present in cultivation. The Bowden is a large fruit, green on the shaded side; its flesh is also pale-coloured. The Byron differs from its parent, being a rich yellow, darker on the sunny side; the flesh is orange and dark red round the stone, and the flavour is singularly rich and good. This variety resembles the Pine-apple Nectarine, but even if the two be grown in the same garden, they will be found sufficiently distinct to merit a separate place either in the orchard-house or on a wall. In spring the flowers of Byron, being very large and brilliant, make a fine display, and the glands, both in this and in the Humboldt, are kidney-shaped.

LORD NAPIER.—This, a seedling from the Early Albert Peach, promises to be one of the best early Nectarines in cultivation. It is some days earlier than Hunt's Tawny, at one time considered the best early kind, and it is greatly superior to it in size, flavour, and appearance. The fruit of Lord Napier is of the largest size, pale on the side not exposed to the sun, but a mottled bright red on the sunny side; its flesh is pale, very juicy, and rich, and separates freely from the stone. Its flowers are large, and the glands of the leaves kidney-shaped. It fruits abundantly and forces well. Hitherto it has proved good both on the wall and in the orchard-house; in the latter it ripens about the end of July or beginning of August, much of course depending on the position which it occupies in the house and the season.

PRUNING DWARF PEARS.

It is well known to every intelligent fruit culturist, that there have been many failures with dwarf Pears. Considering the way in which they have been managed, it is surprising that there should not have been more. Other kinds of trees, as the Apple, Peach, and Cherry have been generally treated with utter neglect, and yet some of them have survived and given tolerable returns. Presuming on this success, most planters are determined to compel dwarf Pears to submit to the same treatment. The result has been the exclamation, Dwarf Pears are a mistake! Cultivation is quite as essential to the growth of the dwarf Pear as to farm crops, and other requisites must be superadded. The stocks must be good and vigorous, and not like many formerly used. The varieties of the Pear must be selected among those which grow vigorously on the Quince, which probably do not constitute a twentieth part of the whole number of sorts. Many fail because they are comparatively unfitted for dwarf growth. Failure sometimes results from a cold, thin, or wet soil, and more frequently from a want of manuring and sufficient culti-

vation. And lastly, a neglect of thorough pruning has been a fruitful cause of failure. The former requisites having been already treated of in former numbers of the "Register," the latter may deserve some further attention. Experience has convinced us, that with good trees, of well chosen varieties, on any good land, which is never too wet; and with good culture and the important—nay more, the indis-

FIG. 1

FIG. 2.

pensable requisite to success—thorough pruning, no one need fail of attaining a degree of success highly satisfactory and profitable.

A dwarf Pear tree should never be planted at one year old. A good one-year-old tree consists of a single upright shoot or stem, from 3 ft. and 1½ ft. to 5 ft. high, and should be cut off at about 2 ft. from the ground; and in order to give a smooth, handsome stem or trunk, let the buds be rubbed off, to the height of 1 ft. from the ground—leaving on the upper portion six to nine buds, more or less;

Fig. 3 (fully formed pyramidal tree).

with the tree standing in its original position in full vigour, and cut back as above stated, each one of these buds will throw out a good strong branch, thereby giving a full round distaff form to the tree, and is the time and manner, and the only time, when that desirable shape can be given, on which the future form of symmetry and beauty so much depends; and to avoid what is termed a crooked or fork-topped tree, in which the two uppermost branches are about of equal

vigour and height, let the second branch from the top be pinched off when about 9 in. or 12 in. long, which will check and weaken it, while the uppermost one becomes a strong central leader; whereas, if the tree be transplanted at one year old, and cut back as above stated, the vital forces of the tree will be weakened four or three-fourths by transplanting, and, as the result, only two or three (more or less) of the buds on the trunk will grow so as to form branches, and those perhaps only at the top or all on one side, while the remaining buds remain dormant, never afterwards to be developed, as the other branches form new channels, which will more readily carry the sap to the other and upper portions of the tree. For transplanting, therefore, let a tree be two years old from the bud, well cut back at one year old, and with six to nine main branches, which form the framework or foundation, which is to give form and character to the future tree, with proper care and management. The annexed cut (fig. 1.) will illustrate a two-year-old tree, as above described, its lower branches about 1 ft. from the ground, its upper branches being the strongest and most upright, and those below less vigorous and more horizontal. I speak of this more particularly, for the reason that all the illustrations which I have noticed in works on Pomology and in horticultural papers, represent a two-year-old tree, with the branches longest and strongest at the bottom, and diminishing in vigour towards the top, except, perhaps, the centre top branch; while all experience illustrates the principle that the sap flows most freely and readily to the upper branches, giving them vigour, strength and uprightness, to the diminution of the same characteristics in those below. The dotted lines indicate where the branches should be cut back at the time of planting. In cutting a tree, with branches formed as above described, let the leader be cut down within 4 to 6 in. of the place where the one-year-old tree was cut off, and just above a good bud on the side of the tree, over the previous year's cut, thus keeping the leader in a perpendicular position over the original trunk or bottom of the tree. If the side branches be too horizontal, upper buds are left for their extension; if too upright, lower buds are left. Side directions may be given, if desirable, to fill wide spaces, in the same way. Cut the other branches at such a distance from the trunk, that the ends of all of them would form a pyramid, the base of which should not be over 12 to 16 in. in diameter, and in small trees much less; thus the lowest branches will be left the longest; the object of which is to check the natural flow of sap to the upper branches, and induce it to flow more forcibly to the lower ones, increasing the vigour and force of the latter as much as possible, which must be done at that time, or never. Fig. 2 represents a two-year-old tree after it has been pruned at two years old, and made the third year's growth, and showing where it should be cut back at that time. All subsequent pruning will become easy to anyone who has attended to these directions thus far—observing the same principles, thinning out or cutting back any secondary or other branches, as shall seem necessary to admit light and air, or give vigour or symmetry of form to the tree; but as the greatest force of sap will flow to the central and upright branches, they will need to be cut back most, retaining, as near as may be, the pyramidal form.—"Rural Affairs."

PLANTING VINES IN INSIDE BORDERS.

PLANTING Vines inside of the house and allowing the roots to grow freely into the outside border is generally found to be the best way of treating them. When planted outside, few roots find their way inside, although a suitable border may have been prepared for them. When planted inside many of the roots take possession of the soil, while others make their way outside. In early forcing it is an advantage to have a good quantity of the roots under cover, and late in autumn or throughout the winter when the fruit is hanging, it is easier to keep it in a state of perfect preservation when the base of the rod and the numerous roots attached to it are indoors. In some cases the roots are entirely confined to inside borders, and, where the Vines are forced early, that plan answers for a time; but their energies soon become impaired chiefly through the restriction to which the roots are subjected. If long and successful fruiting be the object aimed at, plant inside, let the roots have plenty of good material on which to feed, and, at the same time, see that they are in no way prevented from passing to the outer border, which should be well prepared for their reception. In erecting houses in which the Vines are to be planted inside, the foundations are generally set on arches, through which the roots pass into the outer border. There is, however, often too much brickwork, against which many of the roots run, and, following the building downwards, become cramped and crooked and otherwise permanently injured. In such cases it would be almost better to confine the roots inside altogether than to prepare an expensive border which cannot be utilised. It is sometimes considered bad practice to have the roots at a great distance

from the stem, and various modes have been adopted to keep them at home, as it is called; but, so long as they are not twisted or put out of their natural course, it is much better to have plenty of straight healthy roots outside than to have a quantity of distorted ones near the stem. Instead of supporting the fronts or sides of Vineries on brickwork, as has hitherto been done, a better plan is to use cast iron pillars placed about 10 ft. apart, resting on a small block of stone or brick; between each of these there is plenty of space through which the roots may freely run, and standards of this kind are quite strong enough to support the house. A Vinery thus constructed has lately been erected at Aske, the Yorkshire seat of the Earl of Zetland. It rests on standards of this kind, and forms a most serviceable span-roofed house both for Grapes on the roof and for plant-growing under them on the floor. J. MUIR.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Picking over Apples.—For years I practised, says a correspondent of "The American Cultivator," picking over all my Apples two or three times during the winter, and battered myself that I was very discreet in so doing. Last year I had a good many, and grew slack in duty, being busy about many things, and never touched them only as we used them. They kept until July, and were in splendid order. It seems decaying Apples do not injure their neighbours. This year Apples are poor and scarce, but keep well. I think in future I shall put my Apples in a cool, dry place, and disturb them only as I want them for use. [Will some one give an opinion with regard to the advantage or disadvantage of picking over Apples?]

Rotation of Fruit Tree Stocks.—Mr. Fish, in a recent article on renewing orchards, says:—It is merely a loss of time to plant new trees on the old soil. They will not—cannot grow. The earth gets tree-sick, and the only cure for this sort of sickness is a change of crop or a total revival of the earth. There are some who try a mere change of place for the trees. They plant the young trees between the old rows or spaces, forgetting that the surrounding soil has been exhausted by the roots of tree food. It has occurred to us that, provided the soil were suitable, a new stock might be tried with a probability of success. The Paradise, for example, being a surface-rooter, might be tried after the Crab, in cases where a total change is not possible.—W. K.

Hills v. Hollows for Fruit Culture.—President Parmelee, of Michigan, gives his experience of the difference of temperature in various localities as follows:—"I have long held and preached that hollows, from greater cold, are utterly impracticable as sites for orcharding. People will have it that the different temperatures at different points are owing to the variations in thermometers, and a council of instruments was called at the Farmers' Club, at which were present ten thermometers, and the trial showed an almost perfect agreement. Mr. Brinkman brought his up to my residence one still cold evening, and, with mine, was hung on a twig near the house. After ample time to settle, we hung them in my Cherry orchard, lower ground, and they went down 9°. We then carried them about a stone's throw west, to the top of a ridge, and they came up 8°, and the difference of altitude was only 11 ft. We then took them down on the little lake below my house, and they sank 23°. On my return home my thermometer came back to the starting-point."

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

The Earliest Figs.—Allow me to say, in answer to "K. S." (p. 222) that I have noted the following six sorts in several localities all early and of good size and flavour, viz. Brown Turkey, De la Madeline, Bourgeois de Grise, White Marseilles, Brunswick, and Castle Kennedy. Preference might be given to the first three.—J. MUIR.

New Large Currants.—The "Fruit Recorder" says it would rather give £10 per thousand for the Cherry, Versailles, and White Grape Currants, than take the common Currants as a gift. This remark of course refers to their value in markets. The large sorts sell in Buffalo for 6d. or 7d. per quart, while the smaller ones bring only 3d. to 4d., costing more for picking, and as much for packages and express charges.

Too Many Varieties.—Ninety persons out of every hundred who set out trees for home use or for market indulge in too many varieties. This one error has ruined more fruit-growing enterprises than all other causes combined. Nurserymen provide their hundreds of sorts simply because a majority of their customers do not know what they want, and will not take the advice of those who do.

Keeping Back Pot Vines in an Ice-house.—Mr. Temple says, in the "Gardener" that he thinks it probable "that pot Vines may be retarded all autumn by the agency of an ice-house or other means, and then taken in and treated as pot Vines are generally managed for early forcing." [We know it is no easy matter to get very early Vines to break and fruit freely; and if a number of canes grown in pots could be kept back till October, a difficulty would be overcome.]

Vineries.—Vines that were recommended to be started early in February, and that have now broken, may have the temperature raised a few degrees, giving a little air every mild day, but being careful, as soon as leaves are formed, that cold draughts are not admitted, or free development will be seriously interfered with. Amateurs who have a Vinery of this description at work will naturally be anxious to make the most of it by growing other things with their Vines. Some French Beans may now be sown and placed on shelves near the front lights or overhead on the back wall; for these either narrow boxes 10 in. deep, or 10 or 11 in. pots, may be used, draining them and half filling with good ordinary soil, and then sowing the Beans thinly, covering them with an inch of soil, and when they are up and have made some progress, adding more soil, into which the stems will throw out roots that will greatly strengthen them. When grown in this way it is necessary to use considerable care to prevent red spider (to which the Beans are so liable) from getting first established upon them, and from them to the Vines. To obviate this, as soon as the Beans have got to such a size that they will bear it, the syringe must be freely used every day, turning the plants round continually so that the water may get to all parts of the leaves—by no other means can this little pest be kept under. For growing in this way Paris Red, Flageolet, Fulmer's Early Forcing, or Osborn's Forcing will be found free croppers and good in quality. Potatoes may also be successfully grown in pots 12 in. in diameter; these, as for the French Beans, must be drained, an inch of coal cinders will be as handy and answer the purpose as well as crocks; use ordinary soil (if new, all the better), with a little rotten manure added; half fill the pots, putting one Potato in each, and cover with 2 in. of soil, filling up when growth has further advanced. Stand them where they will get as much light as possible. The soil, if heavy, will be benefited by some leaf-mould being added to it; it should not be used when too wet, as when in this condition neither of these vegetables grow kindly in it. A few Strawberries in pots may also now be started, if such were prepared last autumn; but in all cases the introduction amongst Vines of such subjects as the above require care in seeing that they do not interfere with the well-being of the Vines, or the crop of Grapes for the season may materially suffer.

Kitchen Garden.—During the ensuing few weeks more sowing of vegetable seeds, &c. is required than at any other period of the year, but, as has been previously suggested, even when the most suitable time for sowing any particular crop has arrived, it is more expedient, in a wet season like the present, to defer that operations for a week or so, when a great difference in the condition of the soil will, in all probability, have been effected; this more especially applies to situations where the land, despite all that can be done by draining, is retentive of moisture. Where the opposite conditions exist, it is the best practice to sow and plant early, for in such soils it often happens that unless the crops get an early start, to enable them to make considerable progress before the hot dry weather, the latter precludes the possibility of a successful development in the greater number of plants. In the preparation of the ground for culinary vegetables, it should always be borne in mind that soils different in character require to be differently prepared. When the surface-soil is light, especially if the subsoil be of a gravelly or sandy nature, deep rooting crops, like Peas, Carrots, Beet, Parsnips, and Onions, should have a considerable amount of manure dug in deeply when preparing the ground for the roots to feed upon in dry weather. In a garden of this description I once had to manage, for the crops of Peas to come in during the summer and autumn, we opened trenches for the rows as for Celery, but deeper and not so broad—15 in. wide and 18 in. deep; in the bottom of these we placed 6 or 7 in. of marl and well-decayed manure mixed in equal proportions, the marl having lain for a few months exposed to the mellowing action of the weather. By this means the crops exceeded double the quantity that I had found it previously possible to obtain by manuring in the ordinary way, and they bore well late on in the autumn without being affected with mildew. Where marl cannot be had clay will be found a good substitute, aerating it and mixing with manure in a similar manner; if neither marl nor clay be procurable, any new soil of a heavy nature can be used. Amateurs may possibly think that the crop will not be worth the additional labour of such special preparation, but not only will half the breadth of ground so treated produce much more, but the land will be permanently improved. For the other things above-mentioned it is also necessary in light over-dry soils to dig in plenty of manure so that the roots may be well fed during dry hot weather. Dig over ground that was trenched in the autumn or turned up roughly, well pulverising the soil.

Carrots, Onions, and Parsley.—A small breadth of Carrots should be sown on a sheltered border; as with other early sown seeds,

putting in more than would be required later on. In all cases, as previously recommended, sowing in rows, which, although it takes more time to put in the seeds than broadcast, still offers such facilities for thinning the crops and using the hoe amongst them, that it saves time in the end, as well as being more conducive to their general development. Onion ground that was tronched in the autumn, and had at that time anything of a rank nature, such as fowl or pig manure, spread on the surface with a view to its being mellowed by exposure, should have this pointed in, and if a taking of soot and salt be added, it will be a great improvement. The advantage of the first dry day after the ground is prepared to sow the seeds, a good portion of which should consist of late keeping kinds, such as Brown Globe and James's Long-keeping. At the time of sowing the Onions, put in a pinch of Parsley seed at intervals of 2 or 3 ft. in every third row; it will in no way interfere with the Onion crop, and will be found to grow free from canker at the root, vigorous and hardy, so as to stand well the inclemency of the weather, and will be found very different to Parsley crowded together or grown in places where it is shaded by anything else.

Parsnips, Broad Beans, Lettuce, &c.—Parsnips should be sown as soon as the ground is sufficiently dry. It is not desirable to select the best soil or situation in the garden for them, this should be reserved for more important subjects. Another sowing of Broad Beans may now be made. In addition to the already well-purged sorts, Seville Long-pod may be relied upon as a most prolific bearer, good in quality, the stalks bearing almost down to the ground. A little Lance should be sown, both Cos and the small Cabbage variety, Tom Thumb; the latter will come in before the Cos. More Radishes should be put in, this time dispensing with the litter over the beds; also Mustard and Cress, if possible, under shelter of a wall. Plain Cress will, as a rule, succeed better than the double kind.

Cabbage and Cauliflower.—Now put in a little Cocoa-nut Cabbage and Red Cabbage; these latter will do better than the autumn-sown plants in parts of the country where the rainfall is generally light, as in such localities, unless water be supplied liberally in dry periods, they often become stunted; and when the autumn rains come a second growth is made, that very often causes many of the hearts to split, which of course renders them useless for keeping. Choose a dry day to stir the soil amongst autumn-planted Cabbages, drawing some up to the plants; this is necessary if they have suffered from the winds of winter so as to have loosened their hold on the soil round the stem. Some early Cauliflower seeds should also be sown, as likewise a pinch of Veitch's Autumn Giant Cauliflower, and Snow's Winter White Broccoli. Amongst the perplexingly numerous varieties of Broccoli advertised, Snow's may be relied upon as one of the best, and is indispensable to keep up a supply; the same may be said of Veitch's Giant Cauliflower, which is deserving of the high recommendation it has received from all parts of the country; but, to ensure it for as long a season as possible, it ought to be sown several times during the spring, the first of which should be at once.

Potatoes.—It may be well to remind amateurs that after experiments innumerable have been tried with Potatoes to enable them to withstand disease, or with a view to assist their escaping its attacks, little or nothing has been effected except by showing clearly that no dependence can be placed upon any method but growing early and second early kinds with the seeds properly prepared by being wintered cool with as much light as possible to produce strong tough sprouts, which will render them less liable to get injured or broken off in planting; by the avoidance of rank stimulating manures; and by planting sufficiently early to admit of the crop being ready for lifting before the time that the disease usually becomes virulent. With this view I should advise that all garden ground intended to be cropped with Potatoes—as soon as it is dry enough to be prepared for planting—should immediately be got ready. In early planting there is undoubtedly some danger from spring frosts after the plants appear above ground, but, by keeping them earthed up, the danger may be mitigated, and far less mischief will occur from the young leaves being slightly injured by frost, than by the crop being late and exposed to entire destruction by disease.

Stoves.

The present month will be a busy one so far as plant cultivators are concerned, for an examination of the whole stock should be made in order to ascertain in what condition it is in to decide as to which plants it is necessary to re-pot, and which not. Where an increase in the size of the pot is undesirable, the addition of a little fresh soil will be sure to be beneficial if it can be added without injury to the roots. Any plants that have been cut back, or that are now breaking, such as *Justicia*, *Eranthemums*, *Thyracanthus*, *Cyrtantheras*, and others of that class, should be shaken out and

re-potted in smaller pots in rough rich soil. All plants, to be subjected to this treatment, should be taken in hand directly they break, or before the shoots have attained much length, as, when that is the case, they are sure to flag and suffer injury. Others, recently cut down, should be kept dry at the roots till they begin to break, when a good watering will suffice to push the shoots sufficiently forward to render them ready for re-potting; or, where plants of different kinds have to be grown in one stove it will now be necessary to group them according to their requirements, such as separating those that require shade from such as enjoy and are benefited by full sun-light. All recently potted plants, especially such as have been much disturbed at the roots, ought to be placed where they can have proper shade afforded them, and be well syringed overhead until they have become established. With the cold cutting winds usually prevalent at this season, and often accompanied by bright sunshine, air must be admitted with extreme caution. In most cases it will be better to allow the thermometer to run up rather high than to open the roof ventilators at all, unless the external air be soft and genial. The state of the weather should be closely watched, in order to ascertain, if possible, what the day is likely to turn out before fires are prepared to warm the pipes, as it is an easy matter to raise the temperature sufficiently, to suit the light afforded in the absence of sunshine, or to assist the latter. Where air has to be admitted, owing to the pipes giving off heat during the existence of sunlight, the whole of the moisture is soon driven out, and the plants show the injurious effects produced upon them by the flaccid, exhausted appearance which they present after a few hours of such treatment. The very fact of the interior of a stove being hotter than the external air secures for the house and its occupants a certain amount of ventilation that, in most cases, is amply sufficient during at least a portion of the winter and spring months. When strong heat is required, as is the case with most stove plants, and many others that are forced to get them to bloom early, as much of it as is possible should be got from the sun's rays, as that is always more genial and suitable to the growth of plants than such as can be obtained by any other means. Independent of the beneficial results accruing to plants by adopting the above course, it is to be recommended on the score of economy, which, at the present price of fuel, ought to be a great consideration with all. Be this as it may, I am quite of opinion that less ventilation in connection with plant-houses during the winter and spring months would have beneficial results to the plants themselves. Of course some discrimination in this, as in most other matters, is necessary, as some plants, Heaths for instance, require a good deal of fresh air, and dislike a close confined atmosphere, and I may therefore observe that I intend my remarks to apply more especially to such as require a certain amount of artificial heat. As the temperatures of stoves and other plant structures are now being gradually advanced on account of lengthening days, and the consequent increase of light and sun, a proportionate amount of moisture, both at the root and in the atmosphere, must be kept up to suit the requirements of the different occupants. This should always be regulated according to the state of the weather and the amount of artificial heat. On bright sunny days it is almost impossible to have too much, and the air may then be heavily charged by syringing freely, wetting the plants overhead, and damping the floor, walls, and other available surface.

Allamandas.—Any of these that are on trellises should be elevated by placing them on inverted pots, to bring them as near the glass as possible and afford light and air to the lower shoots. Before attempting to train or tie in the young wood of these it should be allowed to harden a little, or it is apt to break out at the base, much in the way in which the young shoots of Vines do. Later plants for succession now breaking should be shaken out and potted in good rough compost, consisting principally of fibry loam with a few lumps of peat and a dash of sand to keep it open. With plants that require such abundant supplies of water while making their growth and carrying their bloom, it is almost impossible to have the soil too porous, as, when it is otherwise, it is apt to become water-logged and sour, besides being unsuitable for the roots of such a quick-growing plant as the Allamanda to penetrate with proper freedom. Where it is desired to increase the stock of these or to work up fresh young plants, the present is the best time for putting in cuttings. These should be taken off with a heel, much in the same way that *Dahlia* cuttings are formed; they should then be inserted singly in sandy soil in small pots and plunged in bottom-heat, where they will soon root, after which they should at once be shifted on into larger pots as they require it. Although the Allamanda is not of much value for cutting, yet single blooms of it, picked off and placed in flat glasses containing damp Moss or Lycopod and water, last for a long time, and may be arranged with other flowers so as to have a showy and attractive appearance. As pot plants with which to furnish conservatories during the summer months Alla-

mandas are most valuable, outlasting, as they do, many of the common and more hardy plants in the same position. They should not, however, be allowed to stand late in the autumn after the night temperature gets low, or they lose a good portion of the young roots, and then it becomes difficult to winter them safely.

Clerodendron Balfourianum.—This is another valuable plant for the purpose just named. In potting plants of this, use a soil consisting of at least two-thirds rough fibry peat to one of loam, which should be put into the pots somewhat loose, in order to allow the roots full play and the water a ready means of escape. Plants of this *Clerodendron* flower in a small state, and cuttings of it put in now are sure to be useful and make good plants for another year. Where the trellises on which these and other plants are to be trained are of wood and have become decayed at the bottom, they may be secured and steadied by running a couple of stout pieces of wire across the top of the pot, to be fastened to another piece run round just beneath its rim. To the ends of the cross-pieces the trellis may be tied, which will render it firm and steady. Wire trellis may be treated in the same way, and can be made almost immovable.

Euphorbia Jacquiniflora.—As soon as the young shoots of this have attained a length of from 4 to 6 in., they should be taken off with a heel and be placed round the edge of a well-drained cutting-pot in light sandy soil, which should then be planged in a good brick bottom-heat. Unless taken off in this way with a piece of the old wood adhering, they are very difficult to strike, and not at all free in doing so even when that is done. As soon as a sufficient stock of cuttings are struck, cut back the old plants to within a few inches of the bottom, and place them in brisk heat, in order to induce them to break again, when they must be shaken out and re-potted. Where convenience exists for planting one or two out, so that they can be trained near the glass, they will afford a large number of heads of bloom for cutting, much longer and finer in every way than such as are usually obtained from pots.

Justicia.—There is always a great paucity of yellow flowers, especially during the winter months. The old but much-neglected *Justicia flavicoma* is one of the best and most effective at that season. To get plants of it of useful flowering sizes cuttings should be put in at once in brisk heat where they will soon root, and should then be potted on in light rich soil to induce them to make strong shoots, without which the individual heads of bloom will be deficient in size. When well grown, the *Justicia flavicoma* is a very effective and desirable plant to have as a winter bloomer. *Justicia carnea* is also very useful, but this has in many places been quite superseded by *Cyrtanthera magnifica*, a plant greatly resembling it, but altogether of a superior character.

Primulas.—Keep those from which seed is desired well up to the light on dry, airy shelves; and, to assist them to set, fertilize the flowers by using a soft camel-hair brush. To get early blooming plants for next winter, seed should be sown at once thinly in pans or pots filled with finely-sifted leaf-soil, or peat, mixed with a small portion of sand. If not thoroughly moist, water a few hours before sowing, and allow the pans to stand and drain before the seed is put in, after which slightly cover with moderately dry soil. Place a sheet of glass over the pan, and plunge the latter in slight bottom-heat to assist the seed to germinate, which, when treated as above, will not fail to succeed.

Plumbago rosea.—This is a charming free-flowering plant for winter decoration, and, although not so lasting as others having greater substance of petal, is exceedingly valuable for growing in small pots to fill vases for table decoration, a purpose for which it is well adapted on account of its bright red flowers, arranged in long graceful racemes. To obtain strong plants of it in 4 or 6 in. pots, cuttings should be struck at once, and then grown on in moist heat on light shelves, where the sun does not strike them with full force. One-year-old plants, if cut back and potted on after they break, will throw up a large quantity of flowers, which are sure to be appreciated when seen drooping over the sides of epergnes, associated with *Lily-of-the-Valley* or other choice blossoms. This *Plumbago* delights in a free open soil, and, in the case of plants in large-sized pots, it can scarcely be too rough. Two-thirds fibry peat to one of loam, with a little sand, will answer admirably. Drain well and water freely while the plants are growing, and ply the syringe overhead to keep them free from thrips, red spider, and other insect-pests.

Propagating Epiphyllums.—This is a good time for increasing the stock of these, either by grafting on the *Pereskia* or *Cereus*, or by cuttings on their own roots. Grown in the latter way, they are well adapted for filling baskets to suspend from the roofs of plant stoves, positions in which they show themselves off to great advantage. Cuttings root readily if inserted in sandy soil and placed on any light shelf in a stove or forcing house. Keep the soil dry till they begin to emit roots, unless they show signs of shrivelling too much,

when a slight watering will be necessary. Although *Epiphyllums* will grow on almost any of the *Cactus* tribe, the *Pereskia* forms the most suitable stock for them, as they can be worked to any height, and be grown either as pyramids or standards. For table decoration, the latter are best, and the most suitable are such as are worked on stems of from 12 to 18 in. high. Just a slit in the end of the *Pereskia*, with a strong branching piece of *Epiphyllum* placed carefully in it, and secured in that position, is all that is required. Before inserting it in the top of the stock, the scion should be cut in the shape of a wedge, corresponding in length with the slit made to receive it. This should be about 1 in., and when placed and tied round, it should be bound up with Moss to keep the cut parts from light and air. Thus treated, both stock and scion quickly unite and form useful compact heads, that, when in bloom, are objects of great beauty. To form pyramids, the scions should be inserted at equal distances apart up the stem of the *Pereskia*, say about 4 in. asunder on the different sides of the stock, so that the grafts do not form regular rows. Make a slight cut in the stock in a downward direction, extending nearly 1 in. in length, and in this insert the scion, which may be secured in its position by thrusting one of the spines of the *Pereskia* through it and the cut part, so as to keep them close together until they have become united. The whole of the stem should then be bound up with Moss, and kept well syringed to keep the grafts plump and fresh. Any old plants of *Epiphyllums* that have grown too large or that are irregular in shape may now be reduced or regulated. This may be done by breaking the branches at a joint, or pruning them out with a knife. Either way the plants may be reduced, thinned, or regulated to any size or shape desired, after which, if placed in brisk moist heat, they soon break again from the tips, and produce a great number of young shoots that, if well-ripened, are sure to flower from every tip. Any plants shaken as above should, as soon as they begin to break, be partly treated out from the old soil, and be re-potted in some good fresh fibry loam and rotten manure; the latter in the proportion of an eighth. *Epiphyllums*, like most other plants, pay for liberal cultivation, although at one time all *Cacti* were limited to a very spare diet, consisting principally of old mortar rubbish, given with the erroneous idea that such treatment induced a free-flowering habit. This can always be brought about by full exposure to the sun and light after growth is complete, and by limiting the supply of water at the root, so as to assist in ripening and maturing the succulent shoots.—J. SHEPARD, *Woolverstone Park*.

Indoor Fruit Department.

Vines started in November will be swelling their fruit fast, and at this particular stage of growth should have a thorough soaking of tepid manure-water, one copious watering being preferable to the same quantity given at various times. Prevent the border becoming sodden by repeated heavy dampings from the watering-pot. Main leaves are preferable to laterals, and where two or three are left beyond the fruit, remove the laterals immediately they appear. Red spider generally puts in its appearance at the commencement of the stoning process; where such exists, wash the foliage with a sponge, using a little soft soap and rain-water. Let the temperature be 60° at night with air, and increasing by day 15°, or 25° by sun-heat. Keep pot Vines clean and well supplied with manure-water. Avoid overcropping, but allow them to carry plenty of foliage, otherwise the fruit is insipid. Eyes put in heat at the commencement of this month should be kept in a temperature of 60° by night, preserving those intended for budding or grafting by placing their ends in water. Pot them on, when the Vines have made a good leafage, to prevent them bleeding. Where Vines have pushed well, disbud as formerly advised, and gradually raise the night temperature to 60°. Keep 2 in. of leaves on the border, to prevent a water-beaten surface, and to admit of a more equable evaporation, allowing the steaming troughs to become dry where fire is the heating agent. During dull weather this will greatly prevent the progress of warts on the foliage, always so objectionable. Stop the side-shoots three leaves beyond the fruit. Tie down such Vines as are of a free-setting nature, leaving only the bunches intended to remain, and thin the clusters immediately they commence to swell. Where Vines are still unpruned, begin at once. Clean as previously directed, and use plentifully Thomson's Styptic to prevent bleeding. Look to Grapes still hanging either in the vinery or fruit-room, and remove all decayed berries. Avoid a high temperature; if dry, it can scarcely be maintained too low at this season.

Pines.—Where early fruit is in demand (if started under former directions, the Pine plants will now have bloomed), with the increased length of light now at command, a heightened temperature will greatly assist in bringing Pines forward. Examine carefully once a week to prevent them becoming dry; damp all available surfaces in the morning and afternoon, and shut up early with as much sun-heat as possible, sprinkling overhead in the afternoon when the

weather is favourable; retain a bottom-heat of 90°, and do not have the temperature of the atmosphere below 65°. Pines in 7 or 8-in. pots, not already shifted, should now have the operation performed. Hand-pull turf previously prepared, retaining only the fibry portion, to every barrow-load of which add a 6-in. pot full of snot and a 12-in. pot full of bone-meal, and mix all well together; place in a warm house for twenty-four hours. Lay potsherds at the bottom of 11 or 12 in. pots, which cover with Moss, adding a layer of snot as a protection against worms. In turning out the suckers, remove all loose soil, and, if badly rooted, shake them out, extricating the bottom whorl of leaves before replacing, and allowing 2 in. for watering and top-dressing, after which ram the compost firmly. If not intended for winter fruiting, Pines should be placed in a bottom-heat of 80°, with a temperature not exceeding 65° during the night. Encourage all growths by day, and avoid overcrowding in the beds—2 ft. square is a good distance.—J. HUNTER.

Figs.—It sometimes happens that these are confined to small spaces built in with bricks; the roots may, therefore, be matted at the bottom, and, though the soil may be in good order as to moisture near the surface, those roots which are to do the chief part of the work for the crop may be starving. A soaking of guano or other good manure-water may, therefore, be given often. Maintain an even temperature, taking advantage of all the sun-heat possible.

Peaches and Nectarines.—At this season the application of fire-heat and proper ventilation are matters of great importance, as the combined influence of sun and artificial heat acting on the tender foliage at the same time, and perhaps a current of cold air passing through the house, are evils which the best and most judicious management in every other respect will do little to counteract. This is one of the most fertile sources of the increase of insect-pests and fruit-dropping. Avoid a meeting of fire-heat with sunshine, when there is a likelihood of a bright day. Stop the artificial heat as soon as possible. Aim at a moderate temperature, with a little air, in preference to being compelled to drive the moisture out of the structure by opening the ventilators to reduce excessive heat. Drafts through the plant or fruit-house, especially when the wind is cold and biting, severely test the constitution of the trees as well as the safety of the crop. "Air early and shut up early" is advice very generally given, the soundness of which we have never seen disputed. Syringe freely early in the morning, also in the afternoon, when the state of the weather demands it. If insects appear, they ought to be dealt with promptly; and Clarke's Insect Destroyer is cleanly, safe, and very destructive to insect life. Well-drained borders—inside—must have plenty of water, and when the trees show signs of weakly growth from over-cropping or from insufficient nutriment, let manure-water be given, noting carefully that it reaches the roots; guano and snot mixed, and water added till the liquid is pale brown in colour, may be used as a safe stimulant; but when the soil is heavy and close, the drainage insufficient, and the roots have suffered in consequence, liquid manure would then only increase the evil. Thin the fruit to one Peach to every square foot, and Nectarines a fourth thicker in the early house. Disbudding must be assiduously followed up as formerly recommended, and where any shoots show a tendency to become gross they should be stopped or taken out, commencing at the tops of the trees, then the central portions, and lastly, the lower parts; but intervals of a few days must elapse between each thinning. Succession-houses in flower must have careful application of the syringe; sprinkling the floors, so that the surfaces may become dry once a day, is a practice which prevents much of the flower-dropping, which so often vexes inexperienced cultivators, and 55° at night need not be exceeded, except when the weather is very mild. Late houses, for the fruit to come in before the crops in orchard-houses and on open walls, may be shut up; the fruit being forwarded chiefly by harvesting sun-heat, only using fuel when the house falls below 45°. Standard and pyramidal trees in pots should not stand where their roots are liable to injury from drying currents; straw or hay bands neatly twisted round the pots generally prevent sudden changes of temperature being felt at the roots; a band of zinc placed within the rim of the pots, and filled up with soil enriched by cow or sheep manure, will do good service where the roots are matted on the surface of the soil; the same treatment applies to orchard-house trees. When the roots are confined in limited space, fumigate the house several times in the week before the flowers open; syringing the trees overhead with quassa water two or three consecutive mornings is a good preventive of aphid, but fine weather must be chosen, especially when the structures are unheated. Shake the trees once or twice daily by tapping them to circulate the pollen when flowering is going on.

Cherries.—Flower-buds commencing to swell must have an even temperature; 45° need not be exceeded, except in very mild weather; the syringe may be used twice daily, but air must be admitted more or less every day. Trees in pots will by-and-by require

plenty of water, and if a small quantity of guano be given with each watering, the fruit will swell to a good size. Preventing the trees from becoming crowded, is a matter which should not be overlooked.—M. T.

Vegetable Forcing.

Cover up Seakale for successive supplies; pots and heating material are not now required; sifted cinder-ashes placed in heaps over the crowns ensure successful growth and blanching. Rhubarb will now grow without any forcing, but may be advanced by placing over the crowns anything at command in the shape of pots, tubs, or boxes. A last batch of Asparagus should be got in, and beds in bearing be stimulated by watering with weak water, and renewal of linings. If the necessary pit or frame room can be had, the next succession of French Beans should be sown in them, rather than in pots or boxes, a gentle warmth, such as that from Oak leaves, 2 or 3 ft. in depth, is sufficient bottom-heat, which should be covered with 9 in. of light rich soil, and the Beans sown thinly in rows 1 ft. apart, adding fresh mould as growth advances. Make up hot-beds for Cucumbers, which will be useful for advancing the growth of many kinds of seedlings till the Cucumbers are ready for planting, such as Capeinicos, Tomatoes, Celery, &c. Keep up a constant succession of Basil, Tarragon, Mint, all herbs, and small saladings, by methodical attention thereto.—W. WILDSMITH, *Hockfield*.

Kitchen Garden.

The extraordinary heavy and continuous rainfall that has prevailed for so long a time has seriously interfered with the work in this department, but now that fine weather may be expected, let every effort be put forth to bring up arrears, and especially in the matter of seed-sowing. Parsnips, Parsley, Onions, Early Horn and James' Scarlet Carrot, Turnips, and early kinds of Potatoes should be got in directly the ground is in a workable condition. The hints, &c., as to sowing or planting that have been given in former notes should be referred to and carried out. Preparation of ground, &c., for the main crop of Potatoes should be made at once. After carefully examining the merits and demerits of early and late planting in reference to the Potato disease, I have come to the conclusion that early planting, which naturally necessitates an earlier maturation of the tubers, is to a very great extent a preventive of the disease. Early planting has but one great drawback, viz., the liability of the haulm to be cut down by late spring frosts, to obviate which, immediately they show above ground, the soil should be drawn over them, and this should be repeated so long as danger lasts. We have practised this system for years, with favourable results. It will now be safe to plant out Cauliflowers on warm borders, moving them carefully from the frames with balls of earth, and planting them with a trowel, in deep drills 2 ft. apart, which latter serve as protectors at this early season. The ground for Cauliflowers cannot be too rich, but, if somewhat poor, as soon as well established, a good soaking of liquid manure should be given. If liable to "club," a good preventive is to put in, with each plant, a handful of different soil to that of the garden; coal ashes, or old mortar rubbish, are also good preventives. An early dish of Green Peas is always highly esteemed in every establishment, so that it is worth while incurring a little extra labour to get them even a few days earlier than usual; therefore, plant out at once, in the warmest position that can be found in the garden, those that have been sown on turf or in boxes, after which assist them to start into growth quickly by protecting with evergreen boughs, replacing these in due time by proper Pea-sticks. Successional sowings should now be made, and should consist of two or three varieties, which, though sown at the same time, will then come in at different periods. The following are all proved good kinds, viz. William I., Advancer, Best of All, Premier, Veitch's Perfection, No Plus Ultra, and British Queen. The new Pea, Dr. Maclean, introduced to cultivators for the first time this season, is likely to prove one of the very best in cultivation. Having had last season an opportunity of seeing its growth and testing its quality, I believe that, for productiveness and quality combined, it will be found unequalled. Peas require growing space according to their height, and it is a good plan to give them abundant head-room and plant Cauliflowers or Coleworts, or sow Spinach between the rows; thus no ground is wasted and both crops are benefited. The three most valuable green crops for obtaining supplies throughout the year, and which never fail through any cause, we have repeatedly proved to be Brussels Sprouts, Dwarf Curled Scotch Kale, and Cottager's Kale, so that these kinds should have precedence over all others, especially in gardens where Broccoli is an uncertain crop, which it generally is in low-lying, damp situations. The above-named three kinds of Brassica should be sown at once; indeed, it is far preferable to sow Brussels Sprouts in the autumn, thus giving them time to get extra long stems, and well furnished with plump

sprouts, before the cold nights check their growth. Seakale that has been forced in the open ground should, as soon as out, have the heating material removed, and let the soil be deeply dug and manured, any old roots dug up by the operation, also those that have been lifted for forcing, being reserved for making a new plantation, which should now be commenced on heavily manured and deeply dug ground, according to the following plan:—Cut the roots into lengths of not less than 4 in., and as thick as can be procured, dibbling them in, in rows 2 ft. apart and 18 in. from set to set, and deep enough to ensure the top of each set being covered with 3 in. of soil, and next winter they will be fit for forcing, either in the open ground or by lifting. The above mode of renewing Seakale plantations is preferable to that of raising seedlings, though if the propagation of Seakale by the latter process be desired, the seed should now be sown in drills 1 ft. apart, and transplanted, as soon as fit to be removed, to the distances recommended above.—W. WILDSMITH.

ADVANTAGES OF A FIRM ROOT-RUN FOR FLOWERS, FRUIT, AND VEGETABLES.

It may at first sight seem inconsistent to recommend deep tillage and at the same time insist upon a firm root-run; but the two things are quite compatible, and, I am convinced, the more completely both can be carried out the greater will be the success. Manure and cultivate well and deeply by all means, but do not plant or sow land when in a loose state. Of course I am aware there is no rule without an exception; for instance, Potatoes, and almost all plants, such as the Yam, that produce their tubers or edible roots completely under ground, are exceptions to the rule I have named in a limited sense, for soil can hardly be stirred too deeply for them, and if allowed a few weeks to settle and to benefit by exposure to the atmosphere, it will be sufficiently consolidated for the operation of planting to be commenced. Where the soil, rainfall, climate, and local conditions of a country like Great Britain vary so much, no one can lay down a hard-and-fast rule to suit all places, and to do so would be as empirical as to prescribe one medicine for all the complaints of the human race. Fruit trees of all kinds will thrive better and come sooner into bearing on firm land well prepared by a proper admixture of soils to a sufficient depth than if planted in beds of loose porous earth. Planting without consolidation or in soil unduly porous may seem a success at first—the growth may be rapid, for the roots, finding themselves in a loose permeable medium, rush through it, as it were, and produce a correspondingly rampant growth in the branches; but if the prepared site had been made firm the roots, instead of rushing through their food, would have ramified and multiplied in it, producing short-jointed wood that would bear fruit quickly. I believe if the soil has been properly loosened and intermixed it is impossible by any mechanical means, such as treading, rolling, or even ramming, to make it too firm for fruit trees. We all know that if we dig a hole in firm unmovable ground it is impossible to make the hole contain all the soil again, and yet roots will penetrate through the hardest ground if there be any food to be got at, and the trees will apparently be all the more fruitful when such is the case. In Vine and Peach borders that are often and hardly a foot allowed to tread upon them, the roots are brought and into the firm land beyond much sooner than is generally supposed, and when that happens to be of an unfavourable nature, lifting and root-shortening should be resorted to to bring them back again. Some people have a notion that frequent digging amongst fruit trees for the purpose of aerating the soil is of material benefit to the trees. Hoe and stir the surface by all means, and if the trees show signs of impoverishment, dig in manure—even if by so doing a few fibres may be destroyed, the increased nourishment given will soon compensate for that—but in well-drained land, after the trees are well established, I think it is preferable to leave Nature to herself. When the ground is fully occupied by active roots, there is no fear of stagnation; there is rather a fear of a lack of moisture than of a superabundance, for where water will go air will follow. No further aeration for the soil is needed by the roots of trees than what they can acquire by their own action, and the constant movement of fluids that takes place in drained land. All vegetables, such as Onions, Turnips, Cabbages, &c., that produce their edible portion above the ground progress more favourably in firm land, provided it has been some time previously deeply worked and made rich by manuring, &c. In the flower garden, if the surface of the land be dry, giving the bed a good treading before planting will be found of great advantage as regards the future development and progress of the plants, especially if it be freshly dug and the soil of a porous nature. E. HOBDAY.

"THE SATURDAY REVIEW" ON MODERN GARDENS.

[THERE is a curious article on this subject in the "Saturday Review." We reproduce it, as it is well that all specially interested in horticulture should know the drift of public opinion on their art; but we protest against its injustice and want of charity, and we omit some wholly unwarrantable statements concerning gardeners, which nobody who knows anything of them as a class could have written: we may add that we are acquainted with many gardeners who would willingly go in the right road, if permitted. All gardeners, with any real knowledge of their art, love variety and nature in a garden, and only require a little encouragement to break away from the artificial and the merely fashionable. No doubt there is a certain type educated wholly under the influences of "bedding out," who will have some difficulty in escaping from its limitations, but even from these we may hope much, for the love of the natural and beautiful is innate in all gardeners who are interested in their work, and it only wants developing.]

The apostles of art in the household, having now managed to persuade fashion to follow in their train for at least a time, will have leisure to turn their attention elsewhere. It would be well if they could be induced to step outside the well-cared-for dwelling-house and engage in a crusade against the modern gardener, a tyrannical and prosaic creature, who holds the same position amongst the flower-pots that the upholsterer does amongst chairs and tables. Our gardens have degenerated for precisely the same reason that our mason-work is commonplace, and our wood-work either distorted by objectless turning or painted in imitation of what it is not. Ignorance and want of taste in those who have money to spend must always have a fatal effect upon every thing produced. Rich people buy stucco palaces, because they have not learnt anything about architecture, and could not appreciate the difference between stone and plaster if they tried. They give orders for costly furniture, but as they have only a feeble idea of what they want, and scarcely the foggiest notion of what they admire, they leave these knotty points to be solved by some firm in whom a titled acquaintance has recommended them to have complete confidence. They value their houses and contents in exact proportion to what they have been made to pay for them. It is precisely the same with their garden. They know nothing about flowers, and can only judge of the merits of their pleasure-grounds by the length of their bills and the number of men they keep employed. It never occurs to them that, just as a drawing-room, however expensively furnished, loses its fascination and air of comfort if left entirely to the care of the housemaid, so no garden can be at all satisfactory without the nameless charm that only can be given by the superintendence of a person of taste and cultivation. It is to be regretted that a larger proportion of those who live at their country places at least nine months of the year, and have nothing particular to do during those nine months, should not take up the pleasant pursuit of artistic gardening, and give to their own family and their friends the pleasure of seeing Nature at her best. At first sight one might suppose that a young lady would feel as much interest in the Roses that grow in the borders as in the artificial ones she places in her bonnet. But here certainly a difficulty does arise, owing to the intolerable position which the ignorance of employers has enabled our gardeners to assume—a position analogous to that taken by our cooks. The ordinary modern gardener, whose only knowledge of plants has been acquired by working in a nursery-ground,* must appear to a real lover of flowers the most insufferable mixture of conceit and ignorance. He makes no attempt to learn how to keep the pleasure-grounds in beauty all the year round, and the kitchen-garden well stocked with necessary crops; on the contrary, his only ambition is to see his name appear on prize tickets at some neighbouring flower-show. He tries to enforce the law that none of the family are to cut the flowers or touch the fruit; but if the lady's-maid happen to be pretty, she will find no difficulty in appropriating the earliest Peach and the most cherished Tea Rose. He cannot, however, bear to see anything given away by his master, and would rather let the Plums spoil on the tree than pack them in a hamper to be sent as a present. He prefers to spend all his energies on producing a few sticks of Celery earlier than anyone else, and a monster Gourd which no one can use. It is rare to see a garden that is under the complete control of an ordinary gardener in which the supply of small fruit admits of the proprietor giving away generously to his poorer neighbours; yet no modern gardener would refuse to force pots of Strawberries, so that he might send in a dozen tasteless specimens for a dinner-party. Amongst the flower-beds he is simply unendurable, as his theory

*He is a fortunate gardener indeed, who learns his business in such "nursery-grounds" as those of Veitch or Backhouse, or Van Houtte or Loddiges. That was,—Ed. GARDEN.

of gardening consists in arranging everything in rows or patches, and on no account allowing any plant under his charge to display the cloven foot of natural habit. To him even a creeper growing at its own sweet will is an eyesore, and he has no opinion of such a Rose as the Cloth of Gold, which refuses to thrive when pruned. A pyramidal Azalea, the shape of a haystack, and so covered with bloom that not a single green leaf is visible to break the monotonous uniformity of its shape, is to him the perfection of art and beauty. In fact, no plant is worth much unless it requires to be kept in a hothouse all the year round. A flower that can grow without assistance is as little entitled to admiration or respect as a lady who does not require a maid to arrange her hair. He hates a Primrose by the river's brim simply because it thrives without being transplanted every year, and no matter how severe the season, bursts forth in bloom to be freely plucked by passers-by. The finest carpet of wild Hyacinths or starchy Wind-flowers is to him mere trash, the tallest and most pearly-white Foxglove only an awkward, lanky weed, to be pulled up and thrown on the rubbish-heap. He disclaims all acquaintance with our common perennial plants, on account of a vulgar way they have of growing anywhere, and a facility for reproduction quite contemptible. He digs up the Monthly Roses, because they are not sufficiently double to please his artificial taste, he burns the wild Honey-suckle, which crept through the hedge so prettily and dared to make acquaintance with aristocratic bedding-out plants. He invariably chooses the hottest part of the day for transplanting and watering, and gathers the fruit when it is raining. He takes possession of every green thing, and resents as an insult the slightest interference. When a suggestion is offered he perhaps replies that, if he is not supposed to know his own business, he had better go elsewhere. Unfortunately he is only too well aware how helpless his employer would feel if left with only a common labourer to whom he had to give directions; yet the amount of knowledge necessary to enable a lady or gentleman to train an intelligent working-man is easily acquired. It is possible to have a charming garden without a greenhouse, and plenty of wall-fruit with only the help of an experienced person to do the pruning. It is the attempt to have vegetables and fruit out of their season, and to cultivate plants which cannot be acclimated, that makes our gardens troublesome, expensive, and unproductive.

[The writer then condemns Miss Hassard's book, which, however, is altogether good in its tendency, as her arrangements of flowers are tastefully and naturally disposed. It is to be regretted that the tasteless and objectionable fashions are not the subjects denounced in such articles, and not the gardener. It is for the owner of a garden to say whether he wishes ribbon borders or a variety of hardy plants, whether he wishes hothouse plants or shrubs and Roses. In many cases the gardeners are compelled to adopt the formal arrangements for which they are denounced.—ED. GARDEN.]

FLOWERS FOR THE WOODS.

THE decoration of our woods and parks with subjects of a floral description other than some of the more ornamental shrubs and trees, and with these only to a limited extent, is a matter which has as yet received scarcely any attention from landscape gardeners and others; but it is nevertheless worthy of consideration, particularly in these days, when we have at our disposal such a wealth of hardy flowering plants well fitted for the purpose. Few scenes strike the rambler in the woods in early summer so much as those sheets of azure produced by the common wood Hyacinth, which abounds in some localities to such an extent as to cover the ground uniformly for miles under the trees, producing, in contrast with the fresh greenery of the woods and undergrowth, quite an enchanting effect. In other places whole tracts are covered with the stately Foxglove which thrives amazingly in the shade; and, when the red, white, and purple varieties are mixed, the effect is rich and telling even at a distance. A bank of Primroses or Snowdrops everybody has of course seen and admired, and there are certainly few plants that brighten up the glades in the wood like the Primrose, which, when the quarters suit it, is quite capable of taking care of itself, and not likely to perish in the struggle for life. These, however, with the Anemone, Violas, and a few other species, are about the only conspicuous floral denizens of the woods and fields in this country. The beautiful *Parnassia palustris*, which we have gathered in abundance on the margins of some of the Scottish lochs, though restricted in its habitat, is a gem, however, that deserves special mention as a subject for planting in marshy situations; and a cold clayey soil seems to suit it as well as any.

To swell the list of subjects suitable for our purpose we must resort to the herbaceous border, confining ourselves to those species which, while they are conspicuous in habit and flower, are likely to

adapt themselves to circumstances, and hold their own—to become naturalised in fact. Among Grasses we may mention the *Arundo* conspicua and the Pampas Grass, both of which have already popularised themselves to some extent as covert plants. They should be planted in masses, and always in dry situations. The Pampas is wonderfully hardy on a dry sub-soil, but wet is fatal to it. The *Arundo* is much hardier, and will succeed where the Pampas Grass fails, but it is a much less striking species. Of flowering herbaceous plants the *Tritoma grandis* ranks among the first. Robust in habit, hardy, not liable to be attacked by game, and brilliantly conspicuous by its tall, bright, flame-coloured spikes—thrown up in great profusion in October and November—it has no equal for effect and showiness. It should be planted in masses in open spaces in the woods where the soil is not wet, but it will grow on any tolerably good soil, and may be left to take care of itself. The plant is now cheap when bought by the thousand or hundred. Though not an aquatic, it is suitable for planting near lakes or ponds, not the least pleasing effect produced being the reflection of the flower-spikes in the water. We have before mentioned the Foxgloves, which are, if anything, better adapted for the purpose in view than the *Tritoma*, and all the cultivated varieties may be raised on the ground from seed sown broadcast, but if the surface of the ground were just barbed and scarified a little with a rake, the plants would get a little start. The common white Lily (*Lilium candidum*) is another noble subject. We have seen it planted extensively in some demesnes where it could receive the little attention it required; but judging from its vitality, and the way the plant grows and blooms annually for many years in neglected cottage gardens, where it is a special favourite, it might be trusted, when once established, to hold its own. Its sweet perfume is distributed far and wide when planted in good-sized clumps here and there. A dry and deep soil suits it best, and, so far as we have noticed, rabbits are not partial to it. One severe winter they ate many Wallflowers and Carnations growing beside the Lilies, not touching the latter. The Tiger and Martagon Lilies might also be used if desired, but we restrict the list to the most likely and easily procurable species. The Daffodil and other varieties of the *Narcissus*, including the beautiful Pheasant's Eye (*Narcissus poeticus*), will of course occur to everyone, though they are not by any means either so general or so plentiful in our woods as they might be. They are certainly ornamental, easily propagated by divisions of the roots just before they die down, and they will thrive and bloom even in a thicket of undergrowth. The common Crocus, too, may be planted extensively. Probably the double *Pyrethrums* would all grow freely, and the handsome pink-flowered *Spiraea* would succeed as well as the common Meadow-sweet (*S. Ulmaria*), so abundant in some localities. To these we may add several of the most vigorous and ornamental *Asters* (*Starworts*), the beautiful pink and white *Anemone japonica*, *Campanula carnica*—the blue and the white—two pretty and effective plants, and very hardy. The *Polyanthus*, with other cultivated varieties of the Primrose and the *Arculica*, would, no doubt, live and thrive beside the common Primrose, and might be planted abundantly near walks and drives; and so would the *Violets* of the robust and sweet-scented *Czar* type. *Phloxes*, *Delphiniums*, and such like, would also thrive untended; and so would the *Iris*, *Lychnis*, *Chelone barbata*—a very likely and effective subject, *Potentilla* of sorts, the Christmas Rose, which will grow anywhere, *Solidago*, the *Valerians*, *Veronicas*, and many others; but those named are common, easily procurable, and hardy, and would afford a display throughout the summer and autumn. In furnishing woods and parks with subjects such as we have named, it would be advisable, with the boldest and most conspicuous at least, to plant in masses and clumps in appropriate situations, notably such attractive species as the *Tritoma* and the Lily, to produce distinct effects; but all the varieties might be distributed indiscriminately along the most frequented paths, the margins of the woods, and other suitable places. The only danger herbaceous plants would be subjected to in such situations would be the attacks of game, and their liability to be overgrown by the more vigorous natives. Few, or none of those named, however, do rabbits care for, even when hard pressed; and as they would be growing when the rabbit's natural food was abundant, they would be in no danger. Of all herbaceous plants, Carnations are the most likely to suffer from rabbits, but they never attack them during the summer.—"Field."

Cowper as a Gardener.—In looking over the "Life of Cowper" the other day, I came upon the following, which I have thought might be interesting to your readers:—"Gardening was, of all employments, that in which I succeeded best, though even in this I did not suddenly attain perfection. I began with Lettuces and

Cauliflowers; from them I proceeded to Cucumbers, next to Melons. I then purchased an Orange tree, to which in due time I added three Myrtles. These served me day and night with employment for a whole severe winter. To defend them from the frost in a situation that exposed them to its severity, cost me much ingenuity and much attendance. I continued to give them fire-heat, and have waded, night after night, through the snow, with the belows under my arm, just before going to bed, to give the latest possible puff to the embers, lest the frost should seize upon them before morning. Very moderate beginnings have sometimes important consequences. From nursing two or three evergreens I became ambitious enough to want a greenhouse, and accordingly built one, which, verse excepted, afforded me amusement for a longer time than any expedient of all the many to which I have fled for refuge from the misery of having nothing to do."

Cypripedium Roezlii.—This, the most robust of Lady's Slippers, is a native of New Grenada, where Roez found it on the banks of the Dagua River, which, according to this celebrated collector, occupies a valley between two ranges of the Andes. The plant, like its ally *C. longifolium*, is a continuous bloomer, although not in the ordinary sense; that is, the plants only produce one, or at most two, spikes annually; but the flowers on these open one at a time, each lasting about a month, and then fading just as the next flower above opens. It is not uncommon to see both this plant and *C. longifolium* in bloom all the year round, during which time the same spike will bear from twelve to eighteen flowers. The glossy, bright green strap-shaped leaves are 2 to 3 ft. in length, the flower-spike being of about equal length. The sepals are of a delicate pink colour, streaked with red, the greenish attenuated petals being margined with bright pink or red, the lip being of a clear greenish-yellow tint.—B.

Achania Malvaviscus.—We advise those who have never seen this to procure it. As a plant for a sitting-room, growing thriftily, needing little care, blooming incessantly, standing dry heat and dust, there are few more satisfactory. We remember (says "Moore's Rural") a specimen of it which fills the whole of a store window in Jackson City not less than 5 ft. wide and 10 ft. high. We had occasion to visit that city once or twice a year for several years; we never saw it out of bloom. Its flowers are a bright red, bearing a general resemblance to those of the single Fuchsia, an inch or more long, tubular, with the petals more twisted or contorted than in most malvaceous plants, and a column twice as long as the corolla. The leaves resemble those of the Sugar Maple, but are softly pubescent. Its growth is so rapid that small plants in the spring will extend over a space 4 ft. in diameter by the autumn, the branches bending to the ground from their own weight and that of their ample foliage. In the conservatory they may be trained so as to cover woodwork as readily as a Vine, and there retained, if so desired, during the entire year; or they may be cut down every spring and planted in the open ground, where, with Abutilons, Pelargoniums, and the double Hollyhocks, they are quite in keeping. This plant is old, but, wherever we have visited, rare. It is raised freely from cuttings or seed.

Flowers in Cemeteries.—A cemetery is most certainly the right place for a profusion of flowers. Of all outdoor monumental decorations these are by far the most beautiful and appropriate. Those who have money to spend upon the last habitation of their friends and relations, and who piously desire to show their love and sorrow by some sort of outward sign, will act more wisely in paying some annual fee to the cemetery gardener to keep churchyard flower-beds trim and pretty, than in laying out a vast amount of money among stonemasons, resulting in ill-executed angels, or trophies of cannon balls and swords and cocked hats, and other such insignia, hinting at the professional career of the deceased. The sums of money spent on these great ponderous symbolical monuments are often very large. But who that has groaned in presence of some hideous specimens of sepulchral bad taste, some terrible combination of cherubs and skeletons, of scythes and hour-glasses, of broken columns and ponderous marble clouds, and who has felt the beauty of one of these flower-begirt graves, will not testify to the superiority of the gardener's work over that of the stonemason? There is, too, a symbolism in the introduction of flowers here which makes them specially fit. These plants have come up from a root which itself was buried in the earth in order that the flower which we admire might bloom. They were put into the ground in the form of seed or bulb with no beauty about them to win our admiration, but they come up in due time arrayed in such splendour of decoration as cannot fail to fill us with admiration first, and then, as we think longer, with hope. They are Grasses of the field whose perishable nature has been made before now to typify the insecurity of human life. Moreover, they suggest, at least, a certain continued supervision, a daily tending and care, which favour the idea that those to whose memory they are sacred are still held in recollection by their friends.—"All the Year Round."

THE KITCHEN GARDEN.

BUNCHING ASPARAGUS FOR MARKET.

ASPARAGUS for city markets must be neatly bunched; in villages we sometimes see it offered for sale loose, but in cities it could hardly be sold in this condition. Bunching is slow work, and difficult to do handsomely without some contrivance to hold the shoots while they are being tied, and to secure uniformity in size. The old buncher (fig. 1) is better than nothing. This consists of a board with four pins 6 in. long, and placed about 4 in. apart each way, to form a square. Two strings, usually of bast matting, are laid down

Fig. 1 (Common Asparagus Buncher).

on the board, which may be set on a bench up against the wall, or have a back made of another board tacked on it at right angles. The Asparagus is laid on the buncher between the pins, the tops touching the back or wall, to keep them even. When the bunch is large enough, the strings are tied tightly, and the butt-end of the bunch cut square; one string is near the bottom, and strong; the other, near the top, may be smaller. There are several mechanical bunchers, the best we ("American Agriculturist") have seen being that invented several years ago, by Mr. S. B. Conover, who has since then considerably improved it. The engraving (fig. 2) shows the construction; the Asparagus is placed in between two brass strips, the hinged part of the buncher is brought down by means of the lever, and held in place until the strings are tied. The bunch

Fig. 2 (Conover's Improved Asparagus Buncher).

is usually 4 or 5 in. in diameter and 8 in. long, the size being usually smaller early in the season than later. Not only does care in bunching pay, but so does care at every step. In cutting, do not long expose the Asparagus to the sun for any length of time, or it will curl up. Before bunching, wash in clean water. Do not bruise the tops. Assort carefully into two sizes, and pack the bunches of the firsts and seconds separately. If the tops of any shoots have "broken," or grown too much, do not bunch them; they injure the sale in the market. Keep the bunches always upright; and if to be kept for some hours before packing, place them on wet hay in a cool, dark cellar. Pack upright in crates as high as the bunches. If to be sent to a distant market, set the bunches on wet Grass and see to the ventilation.

Incomparable Celery.—Most cultivators of this Celery will freely endorse Mr. Groom's statements regarding its good qualities. It is found under different names, but the true kind has been held in

high esteem for over twenty years. It was grown at a place in the west of England many years ago by the late Mr. W. P. Ayres, who discarded all others in favour of the Incomparable. The difficulty is to get the true kind. I was unsuccessful for a number of years till I secured a packet of seed from Mr. A. Moffat, Hindlip Hall, near Worcester. I have had it in excellent condition late in June, and often found a difficulty in getting it to seed. Mr. Moffat, who lives in a favoured district as regards soil and climate, selects a few plants every year, from which he saves his seed.—M. TEMPLE.

SLOPING BANKS FOR EARLY VEGETABLES.

IN most kitchen gardens there is ever a rivalry between early vegetables and the roots of choice fruit trees. The bases of south and west walls are the places first filled with early Peas, Potatoes, French Beans, Cauliflowers, and salads. No doubt the heat reflected from and the shelter afforded by the walls are exceedingly useful in fostering growth; but the vegetables are often grown in such places at the expense of the trees. Partly to avoid this, says the "Country," and also to afford a wider area of sunny sites, raised sloping borders or banks—with a fall to the south is the best—have been introduced in many localities. These may be made of any convenient height or breadth, provided they are large and high enough to prove effective, or be cropped with facility and profit. By altering the slope of the northern or eastern side of such banks we can also aborten and lessen the area of the cold side. That side is, however, about as useful in summer as the warm one, and furnishes the best possible place for the continuous cultivation of Lettuces and other salad plants. The warm, sunny banks are, however, almost equal to the base of a wall for the forwarding of early crops. Carrots, Radishes, Turnips, Peas, early Broad Beans, Potatoes, &c., do exceedingly well on such inclines. Where sheltered places cannot be selected for the formation of these banks, a few thatched hurdles placed at the sides and on the top break the winds, and render the sloping banks more genial than the sides of many walls. Occasionally even a bank of earth may be thrown up on the exposed side. In such cases the wind and cutting draughts are shut out, and the heat of the sun is, as it were, shut in, and its force expended on the fostering of early crops. Such banks are not only useful for early but also for tender crops. In some gardens—which are either too cold or too bleak to mature Tomatoes, Chillies, Ridge Cucumbers, and Vegetable Marrows on the level—such crops may be ripened well on sloping banks. The latter absorb more heat, and reserve it for the plants, reflecting it more thoroughly among them than could be done from a level or even surface. Again, such fruits as Strawberries may be forwarded by at least a fortnight or three weeks when grown on a southern sloping bank. Similar expedients are likewise useful for the cultivation of cordon Pears, Plums, and even choice Apples. These displayed up and down, or, better still, trained across sloping banks, either straight or diagonally, get much benefited by the warmth reflected from the earth, and the crop not only sets, but swells and finishes all the better in consequence. Finally, there is hardly a limit to the usefulness of sloping banks in the kitchen garden: they relieve the cultivator of the necessity of cropping his fruit tree borders, and add much to the area of his warm soil and superior climate for all cultural purposes. Not being preoccupied by any other crop, they are also more completely under the control of the horticulturist, and can be devoted to early or tender vegetables, or early Strawberries, or superior fruit, at pleasure.

CELERY AND CELERY TRENCHES.

ALMOST every cultivator with whom I converse has a theory of his own, according to which Celery running to seed, or becoming hollow in the stems, is explained. For years, like others, I entertained certain notions on this subject, but I was obliged to relinquish them when I found that plants from the same stock, given to friends, did not run to seed as mine did. I knew that their Celery trenches were not prepared with the same care that I bestowed upon mine, for I proceeded upon the assumption that Celery could not have too much manure. For these last six years, however, I have mixed soil with the manure in equal proportions in my Celery trenches, and the result is, that I have seldom a run stick of Celery or one spongy or hollow. Another evil to be avoided in the formation of Celery trenches, especially in light soils, is making them so deep that the manure or compost rests upon the dry or gravelly sub-soil, which naturally absorbs all moisture and substance out of the manure, leaving nothing for the support of the roots. Forming the trenches late in the season is likewise a mistake too often committed; where the soil is light these may be formed in March or even earlier, provided the weather and ground are favourable; trenches made at this season will be found to be exceedingly useful as regards the production of early

roots and salads of various kinds, especially in places where the soil is light, but, under any circumstances, the earlier the trenches are formed the better; indeed, for my own part, I consider this to be a matter of more importance than even the description of manure used. The compost in which I find Celery to succeed best consists of well-decayed cow manure and road-scrappings in about equal proportions, with a small addition of soot, the latter being applied just before laying it in the trenches. My impression is that the cause of Celery running to seed and becoming hollow may, in many cases, be attributed to the unskilful and negligent way in which the trenches are made. Celery being an important crop, I shall feel obliged by any practical hints on its growth and culture with which your readers may kindly favour me. J. THOMSON.

Leeks in Trenches.—After several years' experience in growing these, I find the following plan to be the best:—I sow the seed in the beginning of March, and about the end of May I plant the seedlings in a bed prepared as for Celery, *i.e.*, a trench from 3 ft. 6 in. to 4 ft. 6 in. in width is thrown out, and 12 or 15 in. of rotten manure is dug into it, leaving 5 or 6 in. of soil on the manure. The Leeks are then planted in rows 15 in. apart, and 6 in. asunder in the rows. They are afterwards treated, as regards earthing-up and watering, the same as Celery. The earthing-up is done with boards at three times, the last being at the end of October, or early in November. It will be at once seen how much easier it is to grow well-blanching Leeks by this plan than by the ordinary one of planting them with a dibble in drills, as is commonly done. They are also more conveniently protected during severe frost.—J. E.

The Cardoon in the Garden.—A correspondent of the "sub-tropical" garden rightly recommends the Cardoon for the "sub-tropical" garden. If sown where it is to stand early in April, it will make a glorious plant; but the soil must be rich and deep, or the growth will be disappointing. Before sowing, dig into the positions where each plant is to stand rich manure, and in dry weather give a few good soakings of manure-water. The plants must stand at least 5 ft. apart, or they will be too crowded to show their true character. The plant is more telling and graceful than the Artichoke, and the colour of the foliage more glaucous. It will stand well until sharp frosts come. It is best to sow three or four seeds on each spot, and thin out as they advance in growth, finally leaving only the strongest plant.

Quicken the Germination of Seeds.—We have before referred to the experiments made with camphor as a means of hastening the germination of seeds. Some time ago, Goepfert attributed a similar property to chlorine, iodine, and bromine. According to the "Comptes Rendus," these statements have been recently confirmed by the experiments of Heeckel. Radish seeds exposed to the action of pure water began to germinate after an average interval of eight days; similar seeds, kept moist with iodine water, germinated in five days; with bromine water, in three; and with chlorine water, in two days. The monobromide of camphor was found to exhibit even greater energy than either of its constituents taken separately, or than a simple mixture of bromine and camphor, germination occurring after a mean interval of thirty-six hours. No explanation of this singular property is suggested. The alkaline borates and silicates were found to retard germination, even in relatively small proportions; stronger solutions checking the process for an indefinite period. Arsenious acid and the soluble arseniates prevented germination altogether by destroying the embryo.

Classification of Soils.—Professor Johnston classifies them according to the clayey or sandy proportions, as follows:—1. Pure clay, from which no sand can be washed; 2. Strong clay or brick clay, which contains from 5 to 20 per cent. of sand; 3. Clay loam, which contains from 20 to 40 per cent. of sand; 4. Loam, which has from 40 to 70 per cent. of sand; 5. Sandy loam, which has from 70 to 90 per cent. of sand; 6. Light sand, which has less than 10 per cent. of clay.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Veitch's Autumn Giant Cauliflower.—With me this has proved much harder than Snow's Winter White Broccoli. As regards excellence, I know of nothing with which to compare it. I grow it for market, and find it gives the utmost satisfaction.—G. LEE, Clevedon.

Sawdust as a Foundation for Gravel Walks.—"X. Y. Z." (see p. 234) gives excellent directions for the formation of walks. It may be worth noting that, instead of brushwood as a foundation, sawdust may be used with at least equal advantage. It is sometimes difficult to find a use or place of concealment for sawdust, which is often to be had for nothing, where brushwood might be difficult to get.—SALVOYERS.

Peas and Mice (N. J. V.). When you make a sowing of Peas put some chopped Gorse into the drill at the same time, or rub the Peas in red lead.

QUALITY OF PEARS.

My experience regarding the uncertain quality of Pears exactly coincides with that of Mr. Gilbert (see p. 236). The excessive amount of rain which fell during the past season has evidently had the effect of deteriorating the quality of hardy fruits in general, but more particularly late sorts, which, under ordinary conditions, are so much improved under the bright influences of autumn sunshine. During last September and October there was scarcely sufficient sunshine to promote maturation; hence many of our best varieties of Pears have been barely tolerable as regards flavour, altogether lacking that rich lusciousness so much prized in a good Pear, and only obtainable in fruits perfectly ripened. As a rule the early sorts of Pears have this season been of good size, and clear and beautiful in appearance, but uncertain as regards quality, many well known and highly esteemed varieties generally good being but very indifferent this season. Among these may be mentioned Williams' Bon Chrétien, Beurré d'Amanlis, and Flemish Beauty, the last unfit for table, although fine in appearance, and gathered at various times. To these may be added Autumn Bergamot, Beurré de Capiaumont, Brown Beurré, Marie Louise d'Uccle, Suffolk Thorn, Urbaniste, Beurré Bosc, Durandean, and even Marie Louise—the last good as regards size, but inferior in quality. The same holds good with respect to the majority of early sorts, the best flavoured being British Queen, Beurré Superfin, Beurré Bachelier, Beurré Hardy, Louise Bonne of Jersey, Seckle, Doyenné du Comice, Thompson's, Passe Colmar, Huyshe's Prince of Wales, and Winter Nelis. Those famous and constantly good Pears—Colmar, Chaumontel, Beurré d'Arenberg, Glou Morceau, Ne Plus Meuris, Bergamotte d'Espereu, Josephine de Malines, Easter Beurré, and Beurré Rance are not only inferior in quality, but poor in size. Beurré Rance was delicious here last season, in fact, superior to what it had been for the previous eight years; this season it is perfectly worthless, as well as Bergamotte d'Espereu, a kind which seldom disappoints.

GEO. WESTLAND.

Dwarf Apple Stocks.—In speaking of these (see p. 203), possibly I was not sufficiently clear. My intention was to point out the unsuitability of these dwarfing stocks for planting on light soils, and also their liability sometimes to fall, even where the soil was apparently of a nature well suited to Apple culture. I can assure "W. T." that I had no intention of representing the French Paradise and the Doucin as identical, as anyone who has had any experience with Apples on these stocks cannot fail to know. The Chiswick trial, if it did nothing else, cleared up that question. "W. T." says he has not observed that anyone has recommended the indiscriminate planting of Apples on these stocks in all soils; but if such has not been done, that which amounts to the same thing has, by those who, in speaking of their merits, have not at the same time pointed out their demerits. I am acquainted with several amateurs who, from what they have read of these dwarf Apples, have been induced to plant them in soils wholly unfitted for them—especially, who has recently planted 150 of them in a new garden, on light dry soil, where they will not last half-a-dozen years, whereas if trees upon Crab stocks had been planted, the reverse would have been the result. The greatest infliction upon the thousands of amateurs who at the present day take to gardening, is that many who treat on gardening subjects indiscriminately extol, under all conditions of soil and climate, anything they may happen to recommend, in cases innumerable inducing those who know no better to plant largely things that end in nothing but disappointment.—T. BAINEs.

Antigonon leptopus and Paullinia thalictrifolia.—Can you kindly give me any suggestions as to the culture of these plants?—F. E. T. —[Antigonon leptopus is a South American climber, and does best in a warm humid stove where the temperature does not fall below 60°. Its thick root-stocks should be potted in a fresh open well-drained compost, consisting of turfy loam, leaf-mould, and coarse sand. The Paullinia likes a fresh peaty compost best, and succeeds perfectly in a well-drained pan with a copious supply of moisture at the root when making its growth. When well managed, this is one of the most elegant of stove plants. Heat, moisture, and a fresh open compost are the principal essentials in the culture of these as in that of most other stove plants.]

Flowers in the House.—A sitting-room without a blossom in it in the summer-time is apt to have a desert aspect, for wherever flowers are seen in one, there is always as much sense of companionship as if the little flower-people themselves came visibly with the flowers to inhabit the house. And perhaps in a way they do. For the delicate spirits of grace, of gentleness, of taste, and beauty are seen where a dish of flowers fills a table, where a trailer adorns a bracket, or where a Rose blossoms in a vase. We know when we

see these attempts at simple decoration, be they ever so slight, that there is some one in the house to whom colour and contour and fragrance appeal; some one who loves Nature as much as upholstery, some one who makes an effort after the ideal, the love of flowers seeming so often to accompany the finer traits, the sweetness and quiet and pleasant habits that make a home as happy as the flowers make it beautiful. That they do make home beautiful no one will dispute, and a choice between a room furnished in the simplest way, with plenty of fresh flowers and creepers about it, and a room gorgeous with gilding and velvet and without a blossom, is, for the most of us, something like a choice between a house of light and one of lonely dreariness.

Measurements of an Acre, &c.—The following will be found useful in arriving at accuracy in estimating the amount of land in different pieces of ground under cultivation:—5 yards wide by 988 yards long contain one acre; as do also the following measurements:—10 yards wide by 484 yards long; 20 yards wide by 242 yards long; 40 yards wide by 121 yards long; 80 yards wide by 60½ yards long; 70 yards wide by 69½ yards long; 60 ft. wide by 726 ft. long; 110 ft. wide by 269 ft. long; 120 ft. wide by 563 ft. long; 220 ft. wide by 198 ft. long; 240 ft. wide by 181½ ft. long; and 440 ft. wide by 99 ft. long. A box 24 in. by 16 in., 22 in. deep, contains one barrel; a box 16 in. by 16½ in., 8 in. deep, contains one bushel; a box 8 in. by 8½ in., 8 in. deep, contains one peck; a box 4 in. by 4 in., 4½ in. deep, contains a half-peck.

Celastrus scandens.—This native climber, better known, perhaps, by its popular name, Staffree, presents a grand appearance long after frost has robbed our fields of their summer beauty. It blossoms early in June, and its greenish-coloured flowers are produced in clusters along the sides of the branches. The leaves are of a rich green colour, oblong in shape, and slightly serrated. The berries are roundish or three-cornered in form. When frost appears, the outer covering of the berry opens, showing the shining scarlet pulp surrounding the seed. Here this climber has taken possession of some dead Cedar trees, and at this late season their branches are wreathed in beauty by the long lines of scarlet woven round them. The berries retain their colour, and do not fall for many weeks. This climber is worthy of cultivation, and might be used with good effect in many positions in gardens, cemeteries, &c. It is easily propagated from seeds, cuttings, or suckers.—"Gardeners' Monthly." [Will any reader kindly state if I can obtain this plant in England or where?—B.]

The Late M. Andre Leroy.—This distinguished nurseryman and pomologist, who had the largest establishment in Europe, commenced with a very moderate business. His father began in 1780, with only 2½ acres. The son travelled through Europe, collecting information, and plants and fruits. He rapidly enlarged his grounds, and in 1847, he had raised much more than he could sell. This led to the establishment of his agency at New York, which has continued to the present time. He sent 800,000 or 400,000 trees there annually. He occupied 480 acres, and employed about 300 men. His catalogues were published in five languages.

NOTES AND QUESTIONS—VARIOUS.

The Snowy Mespilus or Bird Cherry.—This, when in full flower, forcibly suggests the idea of a pyramid of snow, so abundantly are its blossoms produced. It forms an excellent background to mixed shrubbery borders, and succeeds well in almost any soil. Its foliage being of a pleasing and delicate shade of green, contrasts favourably with evergreens of a darker hue.—J. G.

The White-berried Pyracantha Hardiest.—The Pyracantha with a red berry, Mr. Meham states, is of no use north of the Potomac. A variety with a white berry is much harder and a closer grower. It has stood as low as 20° below zero at Philadelphia. A Burlington (Iowa) correspondent, states that the white-berried variety there stood 22° below zero, with strong winds and not snow on the ground.

The Weeping Elm.—Than this few deciduous trees look better on Grass in the form of a single specimen. Its gracefully drooping branches, and its totally distinct character, both as regards wood and foliage, from that of the erect kinds of Elm, render it well worth attention, and at this season when its stout side branchlets are covered with flower-buds just ready to expand, it contrasts strikingly with its evergreen associates, of which there is usually a preponderance in pleasure grounds.—J. G.

Bryophyllum calycinum.—Can you inform me as to the habits and proper treatment of this plant? I have a specimen of it that has lost its leaves, and appears to be dying, although it has been kept in a greenhouse.—EKA. [The Bryophyllum in question is, according to our experience, a plant which it is almost impossible to kill; indeed, its vitality is so great that even the fleshy leaves which fall off occasionally push forth little plantlets from their serratures; and in this way the plant is best propagated. We have always found it to do well, even in a sitting-room window, and, in fact, anywhere, provided it is not exposed to frost.—B.]

Tree Planting.—Over 197,000 trees were planted in Minnesota during the tree-planting season of 1875, by contestants for certain premiums which had been offered to those planting the largest number.

No. 226.]

SATURDAY, MARCH 18, 1876.

[Vol. IX.]

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

DIFFERENT MODES OF GROWING TOMATOES.

TOMATOES, when grown and fruited out-of-doors, should be sown in March, either in 6-in. pots or shallow pans, and placed in heat. As soon as the young plants are ready to handle they should be transplanted, one or two into 3-in. pots, in good rich compost. When the roots reach the sides of the pots they will again require shifting into 6-in. pots, and in these they will make strong plants, which, if properly hardened off, will be in good condition for finally planting out at the latter end of May. If it is intended to grow them against a wall, they should have one with a south aspect; they like good rich light soil, and should be well watered in dry weather throughout the summer. If there should be any trace of green fly on the plants before they are put into their final quarters, give them a good fumigating, or syringe them with weak tobacco-water, turning the plants on their sides in order to prevent the liquid from running down to their roots. Two or three shoots from each plant should be trained to the wall at about 1 ft. from each other. When in full growth they will require particular attention as regards thinning the shoots and nailing them to the wall, and where there is space they may be made to look very ornamental. The chief point in connection with Tomato culture is to pinch off the heads continually at the joint above the fruit, for, if allowed to produce two or more eyes before the point of the shoot is pinched off, their fertility is impaired. If there be not space to spare against a wall for a few plants, they will ripen and colour their fruit well if planted in a single row on the wall border in front of the fruit trees, but about 4 or 5 ft. from them. The border should have a south or west aspect, and the plants should be trained to stakes 4 or 5 ft. high. As soon as they have reached the top of the stakes, they should be stopped and kept pinched in. If the young fruit set too thickly, it should be properly thinned out, and a portion of the foliage should be removed where it shades the fruit. The Orangefield is a variety which should be largely grown, especially by those who have only small gardens. In favoured situations in the sunny south Tomatoes may be planted in the same way as we would Cauliflowers, and at about the same distances apart. They must be trained to stout stakes, and if planted in a deep, rich, and rather heavy soil they will produce fruit nearly from the ground to the top of the plant. Experience teaches us, however, that we must not always depend on a crop of fruit from plants in the open air. There are exceptional cases in favourable localities in which the Tomato will grow and produce fruit abundantly, but, on the north side of the Trent this kind of crop in many gardens may be considered a precarious one. All, therefore, who have the opportunity should grow plants during the summer season after the bedding-plants are turned out, under glass. I have for several years grown a quantity of plants in 10-in. pots in a span-roof pit, without any artificial heat, and from these we have gathered sufficient fruit to supply the requirements of a large establishment. One summer I plunged half-a-dozen Sealake tubs in six lights of a pit that had been filled with bedding plants up to the end of May. These tubs were about 18 in. in diameter and 15 in. deep, and in each tub were planted three or four plants, the branches of which were trained over the trellis that had been occupied by the bedding plants. From these were gathered a large quantity of fruit, and the crop no doubt would have been doubled had the plants been properly stopped at the right time. Any vacant space under glass may therefore be utilised in this way. The back wall of a Vinery, Peach-house, orchard-house, or the ends of a greenhouse, would afford ample space for the growth of Tomatoes. If grown in a Vinery or Peach-house they should not be planted in the border to rob the trees of their food, but should be grown in pots 10 or 12 in. in diameter, or in square boxes, and well watered with liquid manure. As regards the summer

treatment of Tomatoes, supposing them to be grown in cold pits or in frames (which offer the best way of securing a crop of fruit in cold districts), they will require carefully tying to upright stakes. As soon as they have formed their first trusses of bloom, the points should be pinched back to two eyes beyond the last truss, an operation which must be repeated from time to time as the plants progress in growth. Air must be admitted on all favourable occasions throughout all stages of their growth, but particularly when the flowers begin to expand and the fruit to swell. The subsequent management is merely a repetition of that already given, viz., supplying abundance of air, keeping them clear of superfluous growths, trimming off leaves that interfere with and shade the fruit, but at the same times preserving as many on the plant as possible, tying out laterals as they advance, and giving the plants a syringing with pure water after a day's hot sunshine. Under treatment of this kind any one may have a good supply of Tomatoes from the end of July to nearly Christmas. Any fruits unripe when the frames or pits are required for other purposes may be cut off, with a portion of the shoot attached to them, and hung up in a greenhouse or any other warm room to ripen. Of varieties I have sown this season Orangefield Dwarf, Hathaway's Excelsior, and The Trophy; the Orangefield is the best for pot culture which I have yet grown, being dwarf and very prolific; it comes into use early, and a single plant will produce a good crop of fruit. Excelsior is one of the best Tomatoes in cultivation, and comes into use early; it is not corrugated, like so many of the old sorts, but is, on the contrary, beautiful in outline, and a first-class kind for purposes of exhibition. The Trophy is a large, coarse-growing sort, with the habit and appearance of the old common red. If I only wanted one variety, I would grow the Orangefield, and if I intended a second kind I would select Hathaway's Excelsior. R.

CELOSIAS AND SALVIA SPLENDENS INTERMIXED.

For conservatory decoration in autumn few plants can equal the different kinds of Celosia. Their fine pyramidal forms, feathered plumes varying from the richest crimson to the brightest yellow, and handsome foliage, render them strikingly beautiful in autumn, when most of the summer subjects have ceased blooming, and before those that flower in winter are in. They associate well with *Salvia splendens*, and have a grand appearance, especially when judiciously intermixed with it. *Salvias* should be propagated in March, and when struck be potted off into 60-sized pots and placed in a pit, in which there is a gentle bottom-heat, near the glass. Keep them rather close for a day or two till such time as they get hold of the soil, when air may be admitted freely during fine weather; pinch all the strong shoots, in order to make them bushy, up to June, but after that they should be allowed to assume their natural form of growth. When they have fairly filled their pots with roots, but not pot-bound, shift them into 32-sized pots, using a compost of good fibrous loam and a little rotten cow-manure. In May they may be gradually hardened off before their final shift into 12-sized pots, or perhaps, what is better and less troublesome, plant them out in a well-prepared sheltered border and liberally supply them with water during dry weather. Here they may remain until the nights begin to get cold, when they must be lifted and potted; keep them cool and shaded and well watered at the roots, sprinkling overhead twice a day for a few days, and they will soon recover, and ought to be got into some light airy house to bring them on ready for the conservatory when wanted. The *Celosias* should be sown in April, in a well-drained pan filled with fine light soil, covering the seeds very slightly. Place the pan in heat, and in a few days they will be up, and when large enough to handle, should be potted off into small 60-sized pots, placing them in a pit in which there is a good bottom-heat near the glass. Keep the pit rather close and shaded for a few hours if the weather be bright until they have become established, when shading should be discontinued and more air given. They must be kept growing freely or they will not get large enough to match the *Salvias*; if shifted, however, into 32-sized pots as soon as the roots begin to work round the pots, and kept plunged in bottom-heat, there will be no danger of them not growing

to the required size. Use a compost consisting of two parts loam, two rotten cow-manure, one leaf-mould, and one sand, all well mixed together. If all go well, in about three weeks from the time when they were shifted into 32-sized pots, they will require their last shift into 12-in. pots, and if they can still have a little bottom-heat, so much the better, but they should have plenty of top air to keep them bushy. When they get hold of the fresh soil, they may be removed to a light, cool pit, and kept well supplied with water. Here they may remain until their associates, the *Salvias*, are ready, when they all may be removed to the conservatory. Some *Celosia* seed sown in July, and its produce grown on, furnishes very pretty and useful decorative plants for the winter if kept in a moderately warm house. W. E. H.

RAISING CROCUSES FROM SEED.

ALL the best varieties of Crocus bear seed freely, except the yellow or orange-coloured ones. In the month of June the seed-vessels may be seen just peeping out of the ground in the centre of the Grass, which about the same time begins to turn yellow, and soon after decays. Every flower produces a seed-vessel, which is white, consequently easily seen. They should be gathered, for if left they will burst and scatter the seeds all over the bed, and will be found troublesome to pick up afterwards. A bed should be prepared by mixing manure with the soil. The seeds must be sown in the autumn (never in the spring) soon after they are gathered, in drills about 8 in. apart and 1 in. deep; they will commence to grow about September, and the plants will make their appearance aboveground in the spring, about the same time as the older corms begin to grow. The first season only two blades of Grass will appear, the second year more blades, and the third year flowers will be produced. A gentle top-dressing should be applied to the seedlings every winter. About July, after the Grass has decayed, the corms may be taken up, and in September or October planted in the flower garden. On no account must the Grass be cut down until it is decayed, or the corms will fail to perfect their growth, and cause them to produce very poor, small flowers. Hundreds of Crocuses are destroyed every year through carelessness while digging manure into the beds, as the bulbs frequently are buried so deeply that it is impossible for them ever to pierce through the soil. It is a good plan to plant Crocuses in clumps at every corner of the beds so that their position can be easily identified. Always have a good reserve of seedling Crocuses in stock; they are always useful, always beautiful. All the choice and varied coloured Crocuses—white, lilac, blue, and striped—reproduce themselves from seed, the yellow ones do not; they are increased by numerous small corms formed underground, which flower when grown to the usual size. The other varieties can be increased in the same way, but the process is slow compared with what can be obtained from seed sowing. Crocuses form new corms every year, which rise upwards; they should be taken up about once in three years and re-planted about 3 in. deep, otherwise in a short time they would grow quite to the top of the soil, having altogether an opposite habit to the Tulip, the new bulbs of which, formed every year, grow downwards. I have seen Tulips which had penetrated the soil upwards of 18 in.

Fencote. H. TAYLOR.

Experiments with Seeds.—Dr. Sargot, of the Botanical Society of France, has lately made some interesting observations on the germination of seeds which have not attained their complete maturity, but the embryo of which has already been formed. To measure the degree of non-maturity, he simply estimated the weight of the uripie seeds which he sowed in fractions of the weight of ripe seeds of the same species. Then he sowed, in good condition as regards soil, temperature, and moisture, seeds weighing one-half, one-third, one-fifth, &c. of what they would weigh at complete maturity. In general he has found that the least ripe seeds are those which germinate the most slowly. The young plants resulting from them remain for a long time stunted; but they ultimately attain their normal vigour. There is not a minimum weight below which a seed ceases to germinate, and which is general for all the species. Thus the *Polygonum orientale*, according to Dr. Sargot, cannot germinate at one-fourth of its normal weight, while *Pisum sativum* still germinates at one-tenth and one-twelfth of its weight. Lastly, he has succeeded in causing to germinate seeds of wheat gathered in July, still green, and with milky perisperms, thus confirming, in a remarkable manner, previous observations made by M. Duval-Jouve and others.

NOTES OF THE WEEK.

— SOME parts of the College Botanic Garden at Dublin are now quite gorgeous with the flowers of that noble Daffodil, *Narcissus maximus*, which attains a height of nearly 2 ft., and is, when grown in rich soil, so large that it more resembles a tropical than a hardy northern flower.

— *XANTHOCERAS SORBIIFOLIA* was exhibited in beautiful condition by MESSRS. VEITCH & SONS (on behalf of Messrs. Thibaut and Keteleer, of Sceaux, near Paris), at the Royal Horticultural Society's meeting on Wednesday last. It is stated to be perfectly hardy, and promises to be a valuable addition to early flowering shrubs. The specimen shown had been lifted from the open ground, and forced in heat. It will be remembered that a coloured plate and description of this new hardy shrub was given in our last Volume (see p. 524).

— THE HON. AND REV. J. T. BOSCAWEN has brought us fresh blooms of *Narcissus heminalis* of Haworth, one of the most distinct of all the early-flowering *Narcissi*, having showy golden slightly odorous flowers and bright green sub-cylindrical leaves 13 in. in length. Mr. Boscawen informs us that the plant came from an old country garden, where it had grown undisturbed for years.

— A VERY singular and fine effect may now be seen in the Phoenix Park, Dublin, where a bold group of tall specimens of *Dracæna indivisa* is in vigorous health in an open position. The effect, too, is all the more striking from the fact that these evergreen and tropical-looking children of the South are contrasted, with numerous groves of bare trees in the great wide park, well swept by mountain breezes.

— MR. WILLIAM FALCONER, one of the staff of THE GARDEN, has been appointed superintendent of the Botanic Gardens, Cambridge, Massachusetts. Mr. Falconer's training and habits of observation fit him well for the important post which he has been selected to fill. The introduction of the many fine hardy plants, natives of North America, but yet unknown to gardens, will, we hope, receive a fair share of attention in the Cambridge Garden, where the opportunities of getting new species are so favourable.

— THE large-leaved Saxifrage (*S. crassifolia*), which now adorns so many gardens, is greatly improved if grown in sheltered spots among shrubs, &c. In the College Garden at Dublin there is now a sheet of it sheltered by some of the fine Hollies for which that garden is so remarkable, and the flowers are more beautiful and fresh than those on the exposed tufts.

— THE Phylloxera Commission has reported that none of the specifics submitted to them is entitled to the prize of 300,000*l.* voted by the Assembly. They state that by applying insecticides to the stock and roots between the 1st of February and the 1st of April the Vines may be protected from the disease, and they recommend the formation of committees in each Department to furnish advice and assistance to the vine-growers. The Minister of Agriculture has accordingly addressed a circular to the Prefects, directing them to confer with the agricultural societies in order to carry out this recommendation.

— AMONG new and rare Orchids shown at South Kensington on Wednesday last were *Ornithidium coccineum*, from Lord Londesborough's collection, a kind which bears coral or scarlet flowers and buds among fresh green *Odontoglossum*-like pseudo-bulbs and foliage. The rare and beautiful *Phalanopsis Portei* is also blooming in the same collection; it has snowy sepals and petals, and a carmine or lilac-purple three-lobed lip. P. Veitchii, exhibited by Messrs. Veitch and Sons, has flowers similar in shape to those of P. Portei, but the sepals and petals are suffused with rosy-lilac. The milk-white *Dendrobium Heyneanum* came from Sir Trevor Lawrence's collection, and a splendid large-flowered variety of *Consol Schilleri* *Phalanopsis* was furnished by Sir H. Peck, as was also a very fine plant of the trumpet-lipped *Dendrobe* (*D. lituiflorum*) bearing forty-three richly-coloured flowers.

— MESSRS. HOOPER, of Covent Garden, showed this week at South Kensington Alpha Potatoes raised this season. They were planted on the 13th of January, and were lifted on the 7th of March, good tubers, excellent in quality. Alpha, being a very dwarf-growing variety, seems peculiarly suitable for frame culture. They were grown by Mr. Barker, of Littlehampton.

— THE fabrication of flower-pots from a mixture of cow-manure and earth is now extensively practised in North Germany. As many as 16,000 were used in one establishment. For forcing they are recommended; they are well adapted for nursery work, for plants raised in pots, and afterwards turned out pot and all. The roots of plants penetrate the sides of the pot, and extract some nourishment from them. They are easily and rapidly made by simple machinery.

THE FLOWER GARDEN.

DWARF CANADIAN CORNEL.

(*CORNUS CANADENSIS*.)

This is a very pretty but neglected miniature shrub, of which each little shoot is tipped with white bracts, pointed with a tint of rose. When well established it is a very ornamental plant, and it is not at all fastidious, but being very dwarf, rarely is suited with a proper situation. It is lost among coarse herbaceous plants, and totally

Cornus canadensis.

obscured by ordinary shrubs; it should, therefore, be planted among Alpine plants on a rock-work, or round or near the edge of a bed of very dwarf Heaths or American plants. It grows about the size of the Partridge Berry, or somewhat larger. Wherever placed, rather damp sandy soil will be found to suit it best. It is a native of North America, in damp cold woods. Growers of British plants may like to possess *Cornus suecica*, but I have never seen it well grown under cultivation, nor is it so ornamental as the preceding.

V.

THE TURFING DAISY.

THIS (in botanical speech *Pyrethrum Tchihatchewii*) is a native of Asia Minor, and one of the ten thousand dwarf plants of the Daisy or Composite Order with which the northern world is inhabited. It is a dwarf hardy evergreen herb, which I first saw in the Paris

Turfing Daisy

Garden some years ago; and it was there used with good effect for covering dry sandy banks, and no doubt it is among the best dwarf plants which may be used for that purpose. The leaves are finely divided and of a rich dark green. The plant is in cultivation in various nurseries, and is of very easy culture. The flowers are white.

R.

SPRING PRUNING STANDARD ROSES.

DURING March or, at the latest, early in April, standard Roses must be thoroughly pruned as follows:—Cut clean out all the dead and small twiggy wood, then shorten the shoots of stout wood to about four eyes, always leaving the top eye in a position pointing outwards. Keep the tree as near as possible in the form of half a ball, and rub off any shoots which grow inwards and cross each other. On going over the trees just before the flower-buds expand it will be found that the top bud on each branch will be more forward than the one below it. If you intend to exhibit, and your blooms are too early,

with six or eight shoots left on the tree, two or three of these top shoots may be cut back to the shoot below in order that the second bud now left may bloom stronger about a week later. Roses, it must be remembered, are very thirsty, and from the end of May the trees must be constantly watered. Even on lawns, where the Grass does much to preserve a moist bottom, it is best to plant them in small sunk circular beds to facilitate the conveyance of water to their roots. To obtain fine blooms their roots must never be dry during the summer, and liquid manure, weak at first, gradually increasing in strength, should be given once a week so long as they are in a growing state, but the supply should be stopped in the autumn to enable them to rest. The drainage of cow-houses, stables, or piggeries, diluted with soft water, forms an excellent fertilizer; if such cannot be obtained, throw about three spadefuls of manure into an 18-gallon cask; fill up with water, and let it stand a day or two to settle; as it becomes reduced, fill up again with water. After the second dose, change the manure, adding water as before. Destroy grubs and green fly as soon as they make their appearance; green fly increases rapidly if the early broods be not annihilated. The trees must be kept cool at the roots, and for this purpose nothing is better than a mulch which retains the moisture well. If the trees be kept in a healthy growing state, they are rarely attacked by green fly or other insects to any alarming extent. To have twenty-four blooms ready on a given day is no easy task in the case of a small collection. The only way to attain this object is to watch vigilantly the progress of the trees, and regulate the time of blooming, by cutting out the top blooms when too early, and trusting to those from the shoots below. Some varieties produce their blooms in clusters; where this is the case, the usual thinning out of buds must be resorted to in good time, but generally it will be found that the best of the exhibition Roses have a habit of producing only one large flower upon each shoot. In the months of May and June, before Roses come into bloom, watering overhead from a garden engine will do much good, and be as effective as at the roots. Play the engine vigorously against the foliage on a summer's evening, and much trouble in hunting for insects will be saved, as they have a wholesome dread of a thorough washing. Suckers must be watched for and grubbed up. Let the shoots be pruned back a little as the trees go out of bloom, it will greatly assist them in throwing out fresh flowers in the autumn.

HENRY TAYLOR.

Fenote.

NARCISSUS MONOPHYLLUS.

PERHAPS your readers may be glad to have a few more particulars concerning this Daffodil, which you have so well illustrated in your last number (see p. 239), and which I call *Corlularia cantabrica*. There is, however, one fault which detracts from the merits of the engraving, viz., that the outer sections of the perianth are flexuose instead of being perfectly straight; this may have been caused from the specimen being partially withered. I must add to your description that the flowers are deliciously scented with the odour of the Orange blossom. I sowed seeds of this plant two years ago; they are growing very well, but, of course, are not likely to flower for some years to come. I received last autumn, from Algiers, several bulbs which had been gathered in a dormant state, having ripened in their native habitat. I planted about fifty of them on their arrival; they all grew without exception, both in pots in a cool greenhouse and in the open ground; but only one bulb produced a flower, and that in the greenhouse. A remarkable circumstance connected with this bulb is that my correspondent in Algeria, at the time he sent mine to England, planted a few of the same in a flower pot, and they all, without exception, flowered. The cause of their not flowering in England as well as they do in Algeria must be the want of sunlight, for the temperature in that country in December averages 60° Fahr., an amount of heat which we can easily command in a greenhouse in England. I imagine that this plant has not been found in Spain since the time of Clusius, for Willkomm and Lange, in their *Prodromus of the Spanish Flora*, do not appear to have seen it either alive or as a dried specimen. Its flowering season in Algeria is from December to March, according to the locality, for it has a very wide range—from the sea-coast at Oran to the borders of the desert. Sometimes, but very rarely, two flowers are produced on the same scape. We have much to learn in the art of bulb-growing. I have bulbs at present from Algeria planted in my garden in 1873, which have lain dormant until the present season, and are now showing leaves for the first time. Others planted at the same time flowered the first year, and then, after refusing to show themselves for a whole year, grew luxuriantly. Mr. Barr is not the only person who has flowered this *Corbularia*, as, in addition to the one flowered at Kew in 1870, Mr. Berkeley informs me that he flowered it last year at Sibthorpe, near Market Harborough. The best figure of this

Narcissus is in the "Exploration Scientifique de l'Algérie," pl. 476, 2' Deval has also a good figure of it in the "Petit Bouquet des Plantes de la Méditerranée" under the name of Narcissus Clusii.

The Holt, Farnham.

G. MURBY.

THE GARDEN VEGETATION IN FEBRUARY.*

By JAMES M'NAB, Royal Botanic Garden, Edinburgh.

FEBRUARY has been rather wintry; snow lay on the ground from the 7th until the 16th, and again from the 25th until the 27th. The thermometer during the month was nineteen times at or below the freezing point, indicating collectively 113°, the lowest markings being on the mornings of the 6th, 7th, 10th, 11th, 13th, and 14th, when 24°, 26°, 19°, 19°, 18°, and 18°, were indicated respectively; the highest morning temperatures occurred on the 17th, 18th, 19th, 23rd, 28th, and 29th, when 38°, 37°, 38°, 39°, 37°, and 38° were indicated. The six highest morning temperatures during January were 41°, 40°, 40°, 41°, 42°, and 42°. During February, 1875, the thermometer was twenty-one times at or below the freezing point, indicating collectively 75°. The following Table shows the amount of frost that occurred during the months of February for the last thirteen years:

1864	165°	1868	10°	1871	16°	1874	69°
1865	98°	1869	6°	1872	13°	1875	75°
1866	38°	1870	7f°	1873	123°	1876	113°
1867	12°						

The snow and frost experienced during the month of February this year has considerably retarded vegetation, which is, however, still somewhat early owing to the mildness of January. The following is a list of spring plants, the dates of flowering of which are annually reported:

	1876.	1875.
Rhododendron Nobleanum	February 10	March 13
Donia Epipactis	" 11	February 5
Bulbocodium vernum	" 16	" 6
Scilla præcox	" 18	January 23
Nordmannia cordifolia	" 16	March 11
Anthriscus grandiflora	" 17	February 15
Sisyrinchium grandiflorum album	" 17	March 6
"	" 20	" 8
Scilla sibirica	" 20	" 10
Iberis gibraltaria	" 21	February 2
Draba aizoides	" 21	March 8
Orobanchis vernus	" 23	" 38
Scilla biflora vera	" 21	" 7

In the rock garden forty-eight species were counted in bloom on the 29th of February, the most conspicuous among them being the different varieties of Hepatica, Helleborus colchicus, H. purpurascens, H. purpurascens minor, Donia Epipactis, Crocus Imperati, Galanthus nivalis and G. plicatus, Lencoujum vernum, Bulbocodium vernum, Rhododendron præcox, Daphne Mezereum, Saxifraga cordifolia ovata, S. oppositifolia, Primula denticulata and P. purpurea, Iberis gibraltaria, and Corydalis angustifolia. There may also now be seen in bloom in the rock garden Veronica rupestris and Lithospermum fruticosum, one or other of the plants of the former species having been in flower more or less since January, 1875, and the latter since April in that year. On the Grass slopes Snowdrops, Crocus susianus, and Scilla biflora are now flowering in abundance. Owing to snow and frost and the general backwardness of the month Snowdrops were not seen in perfection until the 27th. The spring Crocus and its varieties, although flowering more or less from the 28th of January, did not produce a full display of bloom till the end of the month. Most of the shrubby plants mentioned in my last report as being far advanced in consequence of the mildness of the weather in January, have not suffered in any way, but they have progressed but little since that time. The common Stonecrop is now perfectly yellow, although on the 31st of January the golden colour was only visible on a few pieces hanging down some stones facing the sun. No perceptible change has taken place as regards the swelling of the buds of forest and ornamental trees during the month, although several were recorded as being in a forward condition.

Rheum palmatum as a fine-foliaged Plant.—This plant is now very seldom seen, though in these days, when hardy plants with fine foliage are so much sought for, it would be useful to many who would take little interest in it from any other cause. In old days I used to consider it the source of medicinal Rhubarb, but heard that idea was erroneous. Now, however, the Russian botanists have proved that the Chinese Rhubarb, which comes to Europe through Siberia, is yielded by Rheum palmatum; so that this, after all, is one of the genuine Rhubarb plants.—W. T.

A Show of Flower Beds.—An Exhibition of Flower Beds will form part of the arrangements of the Royal Botanic Society for the forthcoming season. The Duke of Teck, president of the Society, will open the new wing of the conservatory on Thursday, June 1, and on the same day an exhibition will take place of flower beds and borders. The beds will be laid out on the lawn and are to be formed with living plants in pots plunged in sand, and to be of a size sufficient for the design to be carried out in the same manner as when the plants are bedded out in the usual way.

Roses from Cuttings.—I am greatly interested in raising Roses from cuttings, and shall be glad if any of the readers of THE GARDEN will give me advice on the subject. I have no glass.—V. [This subject has been frequently treated of in THE GARDEN. Roses may be readily struck in the open ground, and, in fully exposed positions, if cuttings are put in in autumn; they may be put in either in summer or autumn; in summer is the quickest mode, and the cuttings will then require shading for a time. The autumn cuttings thrive best with shading and abundance of water when beginning to push early in spring.—W. S.]

Preserving Flowers without Destroying their Colours.—A French gentleman, M. Boulade, has discovered that if freshly-gathered plants be spread out between sheets of filtering-paper in the usual herbarium manner, and then heated between two bricks in an oven for two or three hours at about 150° Fahrenheit, they will be perfectly and permanently preserved without impairment of the most delicate colours. The process is rendered more rapid and certain if the layer of filtering paper next the flowers be changed after about an hour. If this process be found as effective as above described, it will prove a valuable one, not merely in preserving the colours, but in shortening the ordinary tedious process of drying plants.—R.

Daisies of Corsica.—Corsica furnishes three sorts of Daisies, all of which may be met with in flower in the winter. They consist of Bellis annua, B. perennis, and B. sylvestris. Of these our native type is decidedly the rarest in the Mediterranean island, occurring chiefly in the hill pastures around Pigno, Vico, and Bocognano. The commonest of the three is Bellis sylvestris, the Woodland Daisy, which is scattered with a free hand in the Mâquis bordering on the coast-line throughout the whole island. It is a tall towering Daisy, with long rough leaves that are three-nerved, and a hairy wiry scape that supports the single head of flowers. The marginal florets are rosy-pink on the outside, as in our own species. Decidedly the prettiest of the three is Bellis annua as it opens in the month of January, for as the year advances, it assumes larger and less symmetrical proportions. It is a true lover of the coast-line of the Mediterranean, and I met with many a plant that I might have covered with a florin, that bore one or two flowers with marginal florets of dazzling whiteness. The leaves are light green and crenate, appearing, as in our Daisy, in rosettes.—PETER INCHBALD, *The Lodge, Hovingham, York.*

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

A Happy Marriage.—In rambling by a drive the other day, I came upon an old and stately Scotch Fir, with a long wreath of Honeysuckle growing round its stem to a height of 8 ft. or so. The plant looked vigorous enough, though growing so near the hungry giant, and reminded one of a spaniel crouched in a tiger's lap in some zoological garden.—V.

Christmas Roses.—I see allusion made in THE GARDEN to the large Aberdeen Christmas Rose. It is the Helleborus altissimus; but doubts are entertained as to its being distinct from H. niger. I have never got ripe seeds of it. I do not believe it to be H. abchasicus; I imagine the plant called by nurserymen atro-rubens is H. abchasicus; but the true H. atro-rubens is a very different plant, with the leaves not evergreen.—J. T. B.

Apogoneton distachyon out-of-doors.—"Quo" says (see p. 230) that, according to his experience, "this plant does better in a cold house than in a warm one." It will, I think, generally be found to thrive better in the open air than under glass. Many years ago it used to flower and ripen seed in a pond in the Edinburgh Botanic Garden, and I believe it still continues to do so.—P. GATNER, *Clifford Hall.*

Saffron.—This grows in many parts of Greece, but principally in the islands of Naxos, Mycone, Simi, and Tinos. It is collected by poor women and children, and sent in small lots to Smyrna. The Crocus helleenicus, according to a Greek writer in the "Pharmaceutical Journal," is among the best varieties of Saffron.

* Read before the Botanical Society of Edinburgh, March 9th, 1876.

THE FRUIT GARDEN.

GRAPES IN BOTTLES OF WATER.

I HAVE recently seen the Grape room at Heckfield, now full of fruit, and a remarkable sight it is. It is fitted with three tiers of shelves or racks, running in an horizontal line round the sides of the room; space is thus provided for upwards of 200 bottles, which are fixed in a slanting position, and are all filled with Lady Downes' Grapes, of the finest possible quality. On the lowest computation, each bunch would average 2 lbs., a large weight for this variety. The berries are also large in size, black as sloes, and highly flavoured, the Muscat aroma being very marked. Those who have not yet succeeded in keeping Grapes after this fashion would do well to take a leaf out of Mr. Wildsmith's book, who considers the following the only requisites to keep them successfully. First, a suitable room, which should be dry, with ample means for ventilation and warming when necessary to expel damp. Second, thorough maturation of the fruit before bottling. At Heckfield the Lady Downes are treated to as

Section of Grape Room at Heckfield. Scale 1/2 in. to 1 ft.

much or more heat than the Muscat of Alexandria, and the results seem to justify the practice. Third, the lateral shoots above the branch should not be cut off, but left to divert, as in some measure they must, the water from being taken up by the fruit. Lord Eversley, who takes great interest in all that pertains to gardening, has jocularly named this room Mr. Wildsmith's "Temple of Baccha," we suppose because the Grapes are preserved in old champagne bottles. — Q.

FORCING STRAWBERRIES.

OUR season for gathering this delicious fruit commences the first week in March, for, although they may be procured earlier, I do not find them repay the labour which such hard forcing necessitates, and the flavour is seldom good if ripe earlier, owing to the absence of light. To be successful in forcing Strawberries, especially the earliest crops, so much will depend on the preparation of the plants, that no amount of attention in other matters will compensate for delay in procuring runners, and consequently having the plants but poorly matured; in fact, a good deal of the forcing may be done in the earliest stages of the plant's existence. Procure the earliest runners that can be got; layer them in 3-in. pots, and encourage their growth by thoroughly soaking the parent plants with manure-water, keeping the soil in the pots moist until they are established, when they should be severed from the stools and at once shifted into 6 and 7 in. fruiting pots, using one-year-old stacked turf from a rich pasture, chopped up fine and rammed hard. If any stimulant be needed, weakly-diluted liquid-manure should be added; but for plants intended for early forcing, get a well-ripened crown and a potful of roots as forward as possible, thereby inducing an early season of rest. For the first crop, we prepare a pit filled with a good depth of dry leaves early in November, which gives a mild genial heat to the roots and starts them into active growth before much top-heat is necessary, as even the best plants are easily spoilt by excessive heat in the early stage of forcing. When fairly started into growth, we introduce the most forward plants to shelves close to the glass in

early Peach-houses, or vineries where a mild but gently progressive temperature is maintained. With attention to watering as required, the growth will be sturdy, and flower-spikes will push up strongly, especially if a gentle circulation of air be provided during both night and day. A somewhat drier atmosphere is advisable when in flower, with as much air as the temperature of the weather will permit. We always assist the setting of those in bloom before March with a camel-hair brush, for if imperfectly set, the fruit must, of necessity, be deformed. Succession crops, if carefully attended to, never fail to set every bloom that is allowed to remain on; but, as soon as sufficient blooms are expanded for a crop, we clip the rest off, as the strongest blooms always open first and produce the finest fruit. Strawberries are essentially moisture-loving plants, and if once allowed to get dry enough to droop their foliage, may be considered as permanently injured. Liquid-manure is highly beneficial when the fruit is swelling, but should be perfectly clear, or the soil becomes sodden and sour; give a little at every watering rather than over-strong at any one time. Clear water only should be given when the fruit is ripening, and, if the pots be removed to a cool airy house a few days before the fruit is fit to gather, the flavour is greatly improved. Those not fortunate enough to possess a house specially devoted to Strawberries may provide a very good substitute in a pit heated with hot water; for lofty structures are not necessary, as the plants cannot be too close to the glass. As regards sorts, I have discarded Black Prince for the earliest, and substituted Prince Imperial, of which we have now (March 8) beautifully coloured fruits; for a second early, I find few excel Keene's Seedling in all respects; and, for later kinds, President and British Queen may be relied on everywhere. Some of the newer kinds, like most other kinds of fruits, appear to gain a special notoriety for early forcing in certain localities, which is not fully borne out under all circumstances elsewhere. J. GROOM.

WEIGHTS OF FRUIT.

SOME may not know, says a writer in the "Tribune," that the finest Apples grow in Nova Scotia, but so it is. The largest Apple shown there last year (Chebucto Beauty) weighed 1 3/4 oz.; the second largest (Cayuga Red-streak), 17 oz. The best dozen shown (Emperor Alexander) weighed 10 lbs. 6 oz. The weights of other kinds were:

	lb. oz.	Single Apple
Gravenstein, dozen	6 7	13
Yellow Bellefleur, dozen	5 14	10
Ribston Pippin, dozen	5 10	9
Nonpareil, dozen	5 9	9
King of Tompkins Co., dozen	7 11	12
Blenheim Pippin, dozen	5 8	12
Northern Spy, dozen	7 0	12
Rhode Island Greening, dozen	6 8	12 1/2
Blue Pearmain, dozen	6 9 1/2	11
Esopus Spitzenburg, dozen	5 0 1/2	7 1/2
Gloria Mundi, dozen	9 12	13 1/2
Chebucto Beauty, dozen	9 16	18 1/2
Calkin's Pippin, dozen	5 14	9
Forters, dozen	4 15	6 1/2
Yellow Newtown Pippin, dozen	5 4	6
Clyde Beauty, dozen	9 1	13
Baldwin, dozen	6 8	10 1/2

The largest dozen of Plums (Bradshaw) weighed 27 1/2 oz.

Birds and Fruit.—Last spring a young man in my employment destroyed all the nests of blackbirds and thrushes which he could find before the matter was brought under my notice, and, when I remonstrated with him in reference to what he had done, he stared at me in blank astonishment. He thought he was doing me a service in destroying the eggs and young brood of my enemies at such a season. I know that, in some places, "the taking of nests" in spring is considered to be a more humane practice than killing the birds after they have reached maturity, but, for one, I protest against the destruction of birds' nests. If it be found absolutely needful to destroy birds in the fruit season, let them be killed outright. It is said that only about one in every four of the young birds that are hatched arrive at maturity; but, be that as it may, I protest against the very general idea that prevails, that gardeners are bent upon the wholesale destruction of certain kinds of birds. That many of them sanction their destruction under the plea of necessity is one thing, but the heartless destruction of their nests

cannot be justified in any form. I have been told that egg-shells stuck upon the twigs of Gooseberry bushes, or dwarf fruit trees, prevent birds from eating their buds in spring. I have not had an opportunity of testing this, but any of your readers troubled with birds might soon do so.—J. THOMSON.

Ripening of Pears.—Several varieties of Pears have this season been eccentric as regards their time of ripening; *Easter Beurré*, which usually begins to ripen here about the middle or end of January, was this year perfectly ripe by Christmas, but was not of so good quality as usual; *Glou Morceau*, whose usual time of ripening is about the middle of December, was not ripe this season until after the middle of February; it is now, the first week of March, in excellent condition, and is of first-rate quality. *Knight's Monarch*, which is usually fit for table by the middle of December, does not this year appear to be likely to become melting at all. These varieties have all been produced by trees trained to a wall having a due east aspect.—P. GREYNE, *Culford Hall, Bury St. Edmunds.*

Brazier's Fame Apple.—This excellent culinary variety is fit for use from November to April. It is a conical fruit, very irregular in outline, and one which has large, unequal ribs, that terminate about the eye in large, unequal ridges. Its skin is golden-yellow in the shade, but on the sunny side bright vermilion-striped, and splashed with darker shades of the same colour. Its stalk is generally a mere knob, set in a wide, irregular, deep, and slightly-russeted cavity. The eye is large and nearly closed, placed in a wide, angular, and irregular knobbed and plaited basin. Its flesh is white, crisp, firm, very juicy, and nicely acidulated; altogether it is a beautiful fruit, somewhat resembling in shape and colouring good specimens of the Cornish Gillyflower, but without russet. I received this sort from Writtle, and I believe it to be of Essex origin.—J. SCOTT, *Merrivott, Crewkerne.*

A Continuous-bearing Pear Tree.—"The Grass Valley Union" says: "We have read frequently of late about fruit trees that have borne second crops. Mr. Taylor, who has a fine orchard, has some trees that can bear all second-crop trees. He has a Bartlett (Williams' Bon Chrétien) that ripened a first crop this year, and that first crop has been gathered and eaten. The second crop is now ripe and ready to be gathered; the third crop is almost ripe; the fourth crop of Pears is but little smaller than the third; the fifth is getting along finely, and the sixth and seventh crops show their regular gradations of size in fruit, while the tree is blooming for the eighth crop." [After this our gigantic Mushroom and prodigious Gooseberry may hide their diminished heads. No doubt the fine climate enjoyed by Grass Valley, where we have seen Peach trees growing like young Lombardy Poplars, induced the tree to make its repeated growths.]

The D'Arcy Spice Pippin Apple.—In Mr. Scott's account of this Apple (see p. 222) there is a slight mistake respecting Mr. Harris's place of residence. It should have been Broomfield, near Chelmsford, instead of Baddow. In works on pomology this variety is said to have been first introduced to public notice in the autumn of 1848. This may be true as far as the London public is concerned; for Mr. Harris used to grow large quantities of fruit himself, and also buy fruit for the London markets. He, therefore, might have grown it and brought it to London, but he did not raise it from seed; for Mr. Robert Baker told me that his grandfather used to get this Apple from D'Arcy, and Mr. Baker is now about fifty-five years of age. I well recollect him bringing the grafts to the vicarage at Writtle, in 1854; we cut an espalier tree back and he grafted it himself with the D'Arcy Spice. How it got the name of Baddow Pippin I do not know.—JAS. CLARKE, *Writtle.*

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Late Strawberries in Pots.—Years ago when living near London, I used to see market gardeners taking up young Strawberry runners in March to pot for late work, and with what success Covent Garden proves yearly. Acting on the hint, I always plant out good runners in August, take them up and pot them in March, and grow them in cool houses with the very best results.—R. G. *Burghey.*

Pearson's Golden Queen Grape.—I planted a cane of this Grape last autumn, and although it has had no forcing whatever, some of the young shoots are already more than a foot in length, and on every one of them there is a bunch. Alicantes and Lady Downes planted at the same time and in the same house are not yet in leaf.—VRRIS.

Amateur Vineries.—A very common error that I have observed is that of delaying the pruning of Vines so late that serious injury is done by bleeding. When, as is often the case, the Vinery has to do duty for plant-house as well, a little fire-heat is put on to guard against frost, and the Vines are excited into growth before the owners are aware of it. The safest plan in all such cases is to prune as early after the fall of the leaf and removal of all as possible.—J. GROOM.

A RIVIERA GARDEN IN FEBRUARY.

THE flora of the gardens of Nice and the Riviera generally is so cosmopolitan in character as to defy the efforts of anyone who has not good botanical works at hand to describe it accurately, and from the attendants themselves scarcely any reliable information as to names is to be gleaned; so when we find strange spidery Casuarinas, beautiful Grevilleas, Acacias, Eucalyptus, and all the well-known types of Australian vegetation, jostling Pepper trees (*Schinus Molle*) from Peru, giant bushes of *Wigandia* from the Caracass, just now unfolding their massive heads of purple cheek by jowl with an English Sycamore, *Sparmannia africana* under the shade of the American *Magnolia grandiflora*, the Japanese Medlar (*Eriobotrya japonica*) side by side with the Italian Cypress, Phœnician Olive and Palm, and a thousand other contrasts, yet all thriving equally well, one may be pardoned for not knowing where to begin, or for doubting in what quarter of the globe one is, or what the season of the year may be; and, if from trees and shrubs we turn to flowers, we meet everywhere the same paradoxes, Roses and Wallflowers, Heliotropes and Crocuses, Bougainvilleas and Passion-flowers, Violets, Salvias, and Camellias, all in full flower together, make what seems a strange medley of beauty in the open air for the last days of February. All this is strictly true, but it can only be seen by those who have access to the private gardens of residents who live on the slopes near the Villefranche road or the Cimieri Hill, where the care taken in watering during the long periods of drought and the sheltered position suffice, with half the labour of an English garden, to produce such results. Anybody who hurriedly glanced at the arid mountains and dust-whitened trees in the streets or public gardens would refuse to believe that such Edens are close at hand. The other day when visiting the garden of a lady that is justly renowned for its flowers, there were one or two things so remarkable for the time of year that I cannot refrain from describing them. An arcade of white Roses and Kennedys alternating up the pillars (of Roses, Lamarque, and the old red Bourbons *Gloire des Rosamènes* and *Comte Bobrinski*, and of Kennedys the purple, pink, and white varieties), while overhead a canopy of the large white *Banksia Fortunei* and *Bignonia grandiflora*, already in full flush of early beauty, was a sight not easily to be forgotten; under the grateful shade, bushes of *Daphne indica* and carpets of *Cyclamen persicum* and Neapolitan Violets covered the ground. A little further down the hill the high terrace wall was hung with *Bougainvillea spectabilis* and *glabra* just in flower; *Maréchal Niel*, in every stage, from the full-blown flower to the smallest bud; scarlet and pink Geraniums, and *Linum trigynum*, with its large yellow flowers (almost reminding one of an *Allamanda*) were a blaze of bloom; *Heliotrope* in quantity toning down the gaudiness with its soft lavender flowers added, with *Mignonette*, another sweetener to the already scented air. A large patch of *Echeveria metallica*, with deep, salmon-red flower-stems 6 ft. high, was most striking, and in the less trim parts the Orange and Lemon trees (both in full fruit, and the latter in flower), also were pictures of health and beauty. One variety of Lemon, a Spanish sort, was very remarkable for the excessive thinness of the rind and absence of pips, so that there was twice as much juice as in an ordinary fruit. Many sorts of *Salvia*, and *Tacsonia ignea*, *Camellias*, and *Carnations* were laden with flowers of great beauty, but my attention was specially drawn to the abundance of Roses; few of course at this early season are of show quality, such sorts as *Safrano*, *Souvenir d'un Ami*, *Souvenir de David*, and *Lamarque*, being, with the Red Bourbons I mentioned before, the freest winter-bloomers; but one new kind, evidently a seedling from *Souvenir d'un Ami*, but dwarfer in habit, deeper in colour, and more open in shape, seemed to me of great excellence and size. *Comtesse de Nadailac* is pronounced here to be the most beautiful and sweetest apricot-like scented Rose of recent introduction, but, like *Cloth of Gold* and many other favourites, it is reserving itself for Easter apparently, having bloomed so abundantly in November and December as to require a rest. To obtain this abundance of winter beauty, all the flowers in summer are pulled off, and no more water given them than is requisite to sustain life, when, in September the life-giving

A MEDITERRANEAN SHORE GARDEN.

autumn rains fall, they are severely pruned (excepting Cloth of Gold), and thus produce in November and December—and, indeed, all through the winter—a profusion of flowers, while, after the March rains the blooms are again most beautiful. In the market the masses of Violets, both double and single, Anemones of all sorts and colours, Narcissus, Myrtle, sweet-scented Geranium, Wild Hyacinths (*H. orientalis*), to say nothing of what are called garden flowers, make one long for a time when distance can be sufficiently annihilated for us in England to see something of their freshness and beauty. In spite of the continued drought, deep-rooted trees, such as Planes, are bursting their buds, and Weeping Willows and Almonds are in their loveliest green, but a heavy rain for a day or two falling on the earth, heated by the baking sun of the last fortnight, would make everything grow as if by magic, and fill the Pea-pods that seem to flag in the heat of the last week. Such is the extreme difference between the winter of this sunny region and the wet though mild winters of the west of Europe and England, that it seems wonderful that any plants should be common to both, and adduces another proof of the admirable provision by which they can support such opposite climates.

E. H. W.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Camellias.—Amateurs frequently find considerable difficulty in growing Camellias well, not that they are hard to manage, but by reason of their being too often subjected, together with other greenhouse plants, to one uniform course of treatment of heat, air, and moisture; whereas Camellias require, for a considerable portion of the year, a treatment very different from that of the greater portion of plants usually grown under glass. The result of this is that they are often met with insufficiently furnished with leaves—a condition that at once precludes the possibility of their making sufficient growth, and producing the proper quantity of flowers; in fact, the vexatious disposition that Camellias frequently have of throwing off their buds in the autumn is often traceable to the unhealthy state of the plants, lacking the necessary vigour to bring them to maturity. As the present is the best time of the year to remedy this state of affairs, a few words on the subject may not be out of place. Camellias are plants that require shade, especially when making their growth, at which time they also like a moderately warm situation, with abundance of moisture both at the roots and in the atmosphere. Where there exists a vinery that was started a short time back, they may be placed in a corner, not crowding them too much, and if the Vines be not sufficiently advanced to afford them the requisite shade, a thin piece of scrim should be hung between them and the Vines as a protection from the sun, which this month in bright weather is too powerful for the young leaves of the Camellias. Before putting the plants in heat, if there be any doubt about the soil being sufficiently permeated with moisture, soak them in a pail of water for twelve hours. Syringe them freely every afternoon when the house is closed, and give water to the roots as needed, as they require a greater quantity than most subjects; manure-water, in a clear state, with soot added in the proportion of a handful to two gallons, will much benefit them. Manure-water is sometimes recommended for Camellias at other times than when they are making growth, but I do not think it is of any assistance. Young plants that have made long shoots should have them shortened back; a reluctance to use the knife sufficiently in the early stages is too often the cause of making unhealthy branches in after years. Any large specimens that are thin and deficient in the close, bushy habit indicative of good management, if they have plenty of roots, may be cut in freely, as there are few plants that bear this operation better. After cutting back, treat them as above in other respects, being careful not to overwater until they have made some fresh shoots. If at all infested with scale, they should be well cleaned before being started into growth. Unless in the case of plants that are suffering seriously for root-room, it is better to defer potting until after the growth is made.

Fuchsias.—In a vinery of the description above mentioned, old plants of Fuchsias that have been started for some time will progress more favourably than in a greater heat. As soon as they have fairly broken through they should be turned out of their pots, two-thirds of the old soil removed, and re-potted in new, good ordinary turfy loam, to which has been added one-sixth of rotten manure and some sand, pressing it firmly in the pots; use the old pots if sufficiently large, if not, re-pot in some 2 or 3 in. larger. When potted, put a stick in the centre of each, to afford support; syringe them overhead

every afternoon, but do not give too much water at the root; in a few weeks they will be enabled to bear more. When the young shoots have grown about 2 in., pinch out all the points, to induce a bushy habit. Autumn-struck Fuchsias should also be stopped; as the side shoots require it, pinching out the points of the leading shoot as well; if this be not attended to, they will run up too high, and never have that dense profusely furnished appearance so desirable in well-grown specimens.

Croweas.—To get these most useful long-flowering plants into bloom early in the autumn, they require to be pushed forward in a little heat about this time, with the above-mentioned Fuchsias, cutting them back to within 6 in. of the points to which the shoots were shortened last year. They are liable to brown scale, and if this insect be found upon them before being started, thoroughly wash them with "Fowler's Insecticide," 6 oz. to the gallon of soft water, using it at a temperature of 90°; prevent, as far as possible, any of the mixture from getting into the soil, by placing the plants on their sides until dry.

Miscellaneous Plants.—One of the most useful subjects for either large or small gardens is the old *Calla* (*Richardia*) *ethiopica*. The best system of growing it is to plant it out-of-doors in good soil in the summer; so managed the indoor room is economised and the plants grow much faster and shorter in their leaves than when kept in pots through the whole year. To prepare them for turning out they should, when the flowering is over, be taken out of their pots and the soil shaken from them, after which take off the suckers and pot them according to size, singly or two or three together in 6-in. pots. They will thrive in any ordinary soil to which has been added enough sand to prevent its becoming sour; for, although almost an aquatic plant, *Calla ethiopica* cannot succeed in sour adhesive material; after the suckers are taken off replace the old plants in their original pots, and keep them close until they commence growing, after which place them where they will receive plenty of light to prevent the leaves from being drawn up weakly until the middle of May, when they may be planted out 15 in. apart. This is one of the best room plants that amateurs can grow; and, if managed in the above way, it never gets so long and straggling in the leaves, and will bloom much more proportionate to the size of the plants than when kept altogether in pots. A few Ghent Azaleas, Deutzias, double Chinese Plums, broad-leaved Kalmias, and Rhododendrons, should now be put in any house or pit that may be in use for other plants, with a little heat in it, and will come in usefully either for decorative purposes or for furnishing out flowers. Where Rhododendrons are used, early flowering kinds should be selected, as they will open their flowers with very little forcing, whereas many of the later blooming sorts will not force at all. There are few better for this purpose than *R. caucasicum album*, *R. c. pictum*, and Cunningham's White; these are old kinds, but dwarf and flower profusely in a small state. Hardy shrubs of the above description that have been flowered in pots, and have discontinued blooming, should not be turned out-of-doors without any protection, but ought to have accommodation provided in a cold house or pit until later on, when they can be again planted out. *Deutzia gracilis* makes a first-rate plant grown in pots for forcing year after year; it should be grown in a slight heat after flowering. When it has bloomed, cut out to the bottom all the old flowering branches, as a number of young shoots usually make their appearance from the collar of the plant that will grow on for another year; when their growth is complete they can be plunged out-of-doors in the summer; they will bloom much earlier if required next winter, and with less heat than plants removed from the open ground that had not been so prepared.

Peaches that were started some weeks ago will be opening their bloom; be very careful not to allow the temperature to get too high either by night or day; regulate the amount of heat in the pipes during the night according to the state of the weather, stopping it early in the mornings when there is an appearance of the sun shining brightly. Syringe the trees overhead once a day, and damp the soil inside, but do not render the atmosphere too damp in dull weather, closing the house so as to let the thermometer rise considerably when the afternoons are sunny, and, of course, earlier when they are dull and cold. In fruit forcing, early or later on, it is essential to keep an eye on the weather from morning to evening, and act accordingly, otherwise the extremes of temperature are sure to become fatal to the success of the crop.

Vineries.—Vines that were started as recommended some time back, will by this time have made sufficient growth to require their shoots being tied up. In an amateur's vinery, where there will be many plants grown under the Vines, it is not well to have too many Vines. If the canes be 4 ft. apart, and the bearing shoots stopped at the joint beyond the bunch, and not allowed afterwards

to extend above another joint past where first stopped, the plants grown underneath will obtain a greater quantity of light. The temperature of the house may now be raised a few degrees, but amateurs will do well not to hasten the growth of the crop, as a slower growth is much more likely to be successful. Give a little air on bright mornings sufficiently early to prevent the young leaves from being scalded, opening the top lights a little wider further on in the forenoon, being careful not to admit too much of the cold cutting winds which for some time yet will be too keen for the Vines, even when the sun is very powerful; in such weather distribute plenty of water over the paths and walls, which will counteract the combined drying influences.

Pits and Frames.—Where there are the appliances for growing some Melons to come in moderately early, seeds may now be sown, putting them singly in small pots, as recently suggested with Cucumbers; they will thrive admirably in a Cucumber bed already at work.

The Conservatory.

Passifloras and Tacsonias.—Most kinds of climbing plants will now be starting into growth, and many of them, such as Passifloras, Tacsonias, and others of that class, that flower on the young wood they make, must now be pruned in. The whole of last year's growth should be entirely removed, unless any portion be required for laying in to train over bare or vacant places on the girders or elsewhere. It is best, however, to do this by degrees, so as not to denude the plants entirely of their old foliage till some of the pruned-in part has just started, when the remainder may at once be cut away. This treatment will save any check the plant might otherwise receive if stripped all at once of its foliage. Most of the Tacsonias are worth stripping, but there are two or three that should be in every conservatory of sufficient size to accommodate them; T. Van Volkemii is, perhaps, the most striking, on account of its brilliant colour and the number of flowers it produces. These are borne on long thread-like stems, that move to and fro whenever the air of the house is in motion, and, as they hang so far beneath the foliage, they are shown off to good effect. T. xoniensis is a hybrid between the above and the well-known T. mollissima, and is a very desirable variety. The flowers are of a deep rose-pink colour, with violet throat. The plant partakes more of the hardy vigorous habit of mollissima, and combines the good qualities of both parents as to freedom of bloom. They are very subject to a small white scale, which sticks to the bark and leaves with the greatest tenacity, and is most difficult to eradicate unless very strong solutions of insecticides are applied. As most of the old leaves of these will now be pruned away, a good opportunity will be afforded to get them thoroughly clean before the scale has a chance of effecting a lodgment. To do this, scrub the old bark well with a stiff brush, and every crevice or lurking place in it should be wetted with a solution of Fowler's Insecticide; dose—six ounces to a gallon of soft water. A cleansing of this kind now will keep them free for some time; but, if neglected, the health of the plants will be greatly impaired. Examine whether the borders in which they are growing are in a proper state as to moisture; if at all dry, make sure that they have sufficient water to soak the whole of the border well through to the drainage. Should the plants be much limited as to space for root-room, as is often the case where appearances have been more studied than the requirements of the occupants of such structures, they will be greatly benefited by having as much of the old soil removed as can be done without injury to the roots, replacing the same with some good fresh turfy loam and well-decomposed manure. Where climbers are failing from age or other causes, or are unsatisfactory in any way, the present is the best time for replacing them. This should be done by re-making the border with rough fibry loam, and substituting good strong plants for such as are removed, which will then fill a large space during the summer if properly attended to with water.

Camellias.—Those still carrying a crop of flowers should be assisted by giving them clear soot-water whenever the soil in which they are growing is in a fit state to receive it. If well drained, and the plants are healthy and vigorous, they will take rather liberal supplies of water at this season; at no time should the soil be allowed to become really dry. Where Camellias are planted out they should have what pruning is necessary to confine them to a limited size directly they have discontinued blooming, as delay in this matter means late growth, and, as a necessary consequence, late bloom. In many cases it is often the best plan to allow them to make all the growth they will, and leave them until they have set their flower-buds before any pruning or thinning takes place. After that, any wood grown out of place, or such as is bare of buds, can then be removed; the whole strength of the plant will then be concentrated

in that remaining, so that the flowers increase in size, and are seen to better advantage than if the plant were crowded with wood at the time of blooming. By treating them as above, the young growth is not retarded, as would be the case were the prominent wood-buds cut away, when others in a less forward state of development would probably be at least a fortnight later in starting. Camellia flowers are so much more valuable in winter, lasting double the time than later in the season, that every effort should be made to produce an early growth, as it must be borne in mind that Camellias will not force, and the only way to get early flowers is to get early growth. With this view, any that are in pots should be removed to some forcing house, where they can have the necessary shade, heat, and moisture. A Vinery or Peach house at work will afford this, or failing either of these, any other where they can be kept warm and well syringed, as well as being shaded from bright sunshine will do. When Camellias in pots are out of health, rid the roots of as much of the old soil as can be got away without injuring them, and re-pot in some good rough peat and loam, afterwards plunging the plants in a gently-fermenting bed of leaves or other mild bottom-heat, where they can be treated in the way above described. They will stand a deal of heat while making their young growth, provided the moisture is proportionate. During the earlier stage, the air should be kept almost in a state of saturation, especially if the plants have been much disturbed at the roots. A dry atmosphere is not favourable to the health of Camellias at any time, and where the air is unsuitable in this respect, it is impossible to have them in first-rate condition.

Azaleas that have been forced should, as they get out of bloom, have all the seed-pods picked off, and be placed where they can have a moist heat to enable them to continue their growth. Any that are at all pot-bound ought at once to be shifted into pots of a larger size; those affording the space of 1 in. or so all round the ball will suffice, as it is better to give only moderate shifts than to overpot, especially in the case of hard-wooded plants, where there is always a danger of over-watering. Before potting, see that the balls are properly moist. If there be any appearance of dryness in the centre, soak them through by immersing the pots for twelve hours in a tub of water, and then let them stand and drain for a day or two before potting. By having the balls in a healthy, moist state before shifting the plants, it obviates the necessity of watering till they get hold of the new soil, and unless this be done, there is a risk of its becoming wet and sour before the roots get into it; besides, it is a difficult matter to moisten the old ball if dry at the time of potting, as the water passes too freely through the new soil, while the old is comparatively impervious. In potting, ram the soil as firm as possible, using a properly made potting-stick. The top part of the ball of the plant ought, in a 6-in or 8-in. pot, to be kept about $\frac{1}{2}$ in. below the rim, increasing gradually with the larger sizes so as to ensure them holding sufficient water to permeate the ball thoroughly, thus rendering a second watering unnecessary. See that the peat is good and suitable for the purpose, as well as in a fit state for use. It should be rather on the dry side than otherwise, for if wet, the necessary ramming to get it firm would end in making it close and pasty. Peat, to be rich in vegetable matter, should contain a good deal of root fibre, and be of a dark, nut-brown colour, nearly free of sand. The top part of the spit is sure to be the richest and best on account of its containing more fibre and a larger quantity of decomposing vegetable matter. In potting choice hard-wooded plants, such as Heaths and Azaleas, that have to remain long in the same-sized pots, a careful selection of the soil should be made and saved expressly for the purpose.

Stove and Greenhouse Ferns.

Where these have not been already re-potted no time must be lost, for if the young fronds be allowed to start much in growth before the roots are disturbed the plants receive a check from which they do not recover for the rest of the season, the first and strongest fronds being arrested in their development and becoming crippled and deformed. As it is almost impossible to reduce a well-matted ball of a Fern in the ordinary way by picking the soil out from among the roots, the readiest and most expeditious manner is to cut it clean off with a large sharp knife. Of course, where the size of the pot is no object, and the Ferns are grown for specimens, this practice is not to be recommended, as the best way in that case is to give them a shift in the ordinary way. In most places, however, Ferns are not grown in pots for specimens, but more generally for decorative purposes, and the size has therefore to be limited, and it is better to divide them as described above than to tear their roots in a vain effort to disentangle them. After being cut the main roots soon start a number of fresh feeders, and there are always plenty of others farther in the ball that are ready to push through into the fresh soil, so that the plants are quickly at work again. Few plants are more

tenacious of life than Ferns, or more readily submit to having the roots severed and the ball reduced in the way they do, and this renders them of more value for decorative purposes, as they can be kept to any size. Gymnogrammas showing two or three distinct crowns may be split through and reduced in that way, when each will make a separate plant. Adiantums and others of that class may be cut into as many pieces as desired, and each will soon commence to grow vigorously when potted in fresh soil. The beautiful *A. Farleyense* divides readily, and may be as safely operated on in this way as any of the commoner varieties. Gleichenias are more difficult to manipulate, and should therefore be handled carefully. These may be increased by layering into other pots any of the wiry rhizomes that sufficiently protrude. As soon as growth has commenced, watering must become more frequent, especially in the case of such as are cramped for root-room, in which state, with free drainage, they can scarcely have too much. Syringes freely overhead at least once a day, whenever the weather is bright and clear, all except Gymnogrammas, which become much disfigured if the dust-like powder be washed on to the upper part of the fronds. If these be syringed at all, it must therefore be very lightly, and so as not to hit the undersides, simply allowing the spray to fall as a mist over their heads. Gradually remove the old fronds as the fresh ones emerge from the crowns, and watch closely that no young scale fix themselves on the young leaves, or they will spread with great rapidity. Keep the air of the houses close and moist for the present, to encourage the plants to make a start and take hold of the fresh soil, after which air in moderation may be admitted whenever the weather is favourable. Be prepared with the necessary shading material to put on houses much exposed to the sun, unless creepers are grown for the purpose, which are preferable, if they be kept within due bounds.—J. STEPHARD, *Woolverstone Park*.

Hardy Fruits.

If we may take the quantity of buds as an earnest of the fruit crop, the prospects for the present season are really good, for all kinds of fruit trees are exceptionally well furnished in that respect. This is the more surprising if the unfavourable character of the weather for maturing their growth during the greater part of last summer and autumn be taken into account, and though of a necessity there must, through the cold, unless weather, be a large per centage of malformed or improperly developed buds, still, if the spring frosts do not prove too destructive to the blossoms when open, we may reasonably anticipate a fruit harvest of more than average abundance. How to prevent the blossoms unfolding till all danger from frost is past is a problem that still requires solving. Now that Apricots and Peaches are in flower, see that every attention be paid them to ensure a successful set; the blinds or coverings should be let down every night, and it will be advisable to keep them covered during the prevalence of cold north-easterly winds or heavy rains, and if the sun should be very bright they should also be drawn down for a couple of hours in the middle of the day. If bees be not seen at work amongst the blossoms, shake the trees once or twice daily to distribute the pollen. I was last season taken to task because I advised that, if Gooseberry bushes were in bloom and a sharp night seemed imminent, they should be protected by shaking dry hay or bracken over them; but I only spoke well of "the bridge that had carried me safely over," and therefore reiterate my conviction of the utility of such a preservative practice. Small bushes of Apples and Pears, or lines of cordons, may readily be protected by treble-ply fish netting, tiffany, or the thick spray of Birch or Fir branches, laid against the trees; at any rate, if the blossoms be there, and the weather threatening, the determination should be to save them at any cost of labour or trouble. Figs that have been protected during the winter should have been uncovered ere this, and the shoots nailed or tied to the walls. As a rule, pruning of them is at this season undesirable, though if crowded the most weakly shoots may be taken out. On cold nights, protection must be given, or the embryo fruit will drop as soon as the sap gets into active motion. The season for grafting Apples and Pears is at hand—indeed, may now at any time be performed if scions of new or improved varieties can be obtained. Many so-called improved kinds of both have of late years made their appearance, and though some have been disappointing, others have proved to be real acquisitions, amongst which may be named the following:—*Apples*: Lady Henniker, Annie Elizabeth, Lord Suffield, Peasgood's Nonesuch, and Balchin's Pearmain. *Pears*: Brockworth Park, Madame Treve, Pitmaston Duchess, Beurré Hardy, Beurré de l'Assomption, and British Queen. All the above-mentioned are, without exception, first-class additions to our lists of fruits. Remove the ground-suckers from Nut trees, and thin out straggling branches, that being all the pruning that is either necessary or desirable. It is not yet too late to make a plantation of them; a row makes a good boundary to an orchard, or a capital screen and protection to an exposed part of the kitchen garden.—W. WILDSMITH, *Heckfield*.

PLATE XII.

ROSE CATHERINE BELL.

Drawn by H. HYDE.

THE annexed illustration is a faithful representation of a new seedling Rose raised by Messrs. Bell and Son, of Norwich, but not yet distributed. Its conical form and thick, revolute petals give it a distinct appearance, while in colour it is bright and effective, the inner sides of the petals being a glowing crimson, and their backs a delicate, silvery rose, inclining to lilac. In foliage and general habit it somewhat resembles *Centifolia rosea*, but even surpasses that well-known variety in vigour. It will, therefore, form a valuable addition both to out and indoor Roses. Its blooms last long in beauty in a cut state; indeed, the flowers of it, sent to THE GARDEN office for the use of our artist, retained their freshness longer than other kinds cut at the same time, and placed under the same circumstances. Many of our best new Roses of late years are English seedlings, which are now becoming so numerous that it may soon be desirable to have classes set specially apart for them in flower-show schedules, in order that we may be able to show them against the best of the French varieties. We have recently directed attention to the facility with which new Roses of undoubted merit as regards hardiness, vigour, form, substance, and colour, can be raised in our gardens, and we again refer to the subject with the view of inducing English Rose growers to commence the raising of seedlings in earnest, seeing that those who have already tried the experiment have reaped such splendid results. That lovely Rose, *Deviensis*, was accidentally raised from a seed-pod of Smith's *Noisette*, which its raiser, Mr. Foster, of Devonport, bought, simply from the fact that the seed-pod borne by it was nearly ripe; and so highly was this variety esteemed that the late Mr. Pince, of Exeter, "booked" 1000 one-guinea orders for it ere it was distributed. Roses being everywhere welcomed and cultivated for their beauty and fragrance, it follows that a really good and distinct seedling is of considerable value to its originator. One of the first of all requisites in raising new Roses is to select vigorous varieties of first-rate excellence, and, as a matter of course, it is necessary that they produce seeds freely. Amongst seed parents in the Hybrid Perpetual class we have found General Jacqueminot, Jules Margottin, *Centifolia rosea*, *Gloire de Santeny*, and John Hopper to be good; and some of the best of our new Roses have been obtained from these kinds. It was long thought impossible to obtain crosses between varieties belonging to the Hybrid Perpetual and the Tea-scented sections, but this has now been effected by M. Lacharme, who has his seed-bearing Roses trained on a south wall, where they begin to flower in April; but, says that eminent French raiser, these first flowers are very full and but little disposed to bear reproductive organs, consequently little adapted for fertilisation. It is necessary to restrain the first blooming, so as to arrive as soon as possible at the second flowering about the end of June. These later flowers are not so double, and are better adapted for the purposes of fertilisation; and he remarks that while some have recourse to artificial fertilisation, he has little faith in it, and does not practise it himself, although he adds that the seed-bearing plants should be from ten to twenty years old in order to produce really good new kinds. Most of the Hybrid Perpetual class ripen seeds in the open air in this country, but in the case of the more delicate Tea-scented and *Noisette* varieties it is advisable to plant them under a sunny glass-covered wall. The seed-pods should be gathered in dry weather as soon as they are ripe, and stored in pots of dry sand until spring, when they may be opened, and the seeds sown in well-drained pans of fresh, open, sandy compost, and placed in a cold pit or frame to germinate. Seedlings thus treated make rapid growth, and often flower the following year, but it is difficult to form any opinion of their merits until they are two or three years old. If they show any signs of future excellence, it is well to work a few buds of them on the Briar or Manetti stock, so as to give the variety a better chance of full development. The history of the early variations of the Rose is lost in obscurity; but there can be no doubt that the Roses of our own time have originated from the blending together of the different species. B.

THE INDOOR GARDEN.

THE CHRYSANTHEMUM, BOTH FOR EXHIBITION AND CONSERVATORY DECORATION.

By F. T. DAVIS, Plumstead.

THE Chrysanthemum, owing to the ready way in which it adapts itself to any soil or situation, is eminently suited for town gardens, being an excellent smoke-resisting plant and one that amply repays the cultivator for any extra labour bestowed upon it. Specimens for exhibition certainly require considerable attention and plenty of stage room, but those who merely desire flowers for decoration in a cut state, and who have but limited time and space to spare may, by attention to the following directions, be able to have a display of flowers from the first week in September onwards well into January by growing such kinds as Katherine Talfourd, Jenny Lind, Mr. George Haskin, Virginala, and some of the Japanese section. The value of Chrysanthemums for church decoration, as well as for general purposes at Christmas, appears to have been overlooked, as by a judicious selection of varieties the conservatory may be made to look quite gay at that festive season.

Flat-topped or Convex Plants.

Few subjects for purposes of exhibition excel in effectiveness Chrysanthemums grown in this way. In starting plants of this kind, two or three modes are employed, though of course they all resolve themselves into one after the first or second shift. Let us suppose that the grower wishes to produce a large convex specimen, such as is usually grown for exhibition, and further that he has not stock with which to begin: his mode of procedure will be the same as mine was the first year, in which I commenced to grow specimens, although in the next and succeeding years he will be able to get a larger plant, from the fact that he will have old stools with which to deal. Obtain some strong well-rooted cuttings established in 60-sized pots; these should be stopped (*i. e.*, the top taken off with the finger and thumb), to about four or five joints. Some recommend the extreme point only to be taken off, but, speaking as I do from experience, I can certainly say that such a course is not to be recommended, for if the joint only be removed the bottom eyes will not start, and the cultivator's aim should be to get as many breaks as possible from the first stopping. The course which I generally adopt is, to allow the plant to get about 10 in. or 12 in. high, and then to reduce it to four or five joints, thus ensuring the whole of them breaking. Supposing the plants to be kept in a temperature of about 50° or 55°, they will in a few days commence to break, and as these breaks form the groundwork of the future specimen, great care should be taken to induce good, free growth. As soon as the breaks are about 1 in. long, the plant will be ready for a first shift. The sized pot into which I generally shift is that known as a 48 or 5-in. An important point, and one to which I would direct the special attention of cultivators, is never to shift and stop at the same time advice certainly old, but nevertheless good. About a fortnight or so after shifting the plant into a 48-sized pot, it will be ready for another stopping, and as before care must be taken to ensure all the eyes breaking, as these breaks so multiply themselves that they are of the utmost importance where good-sized specimens are wanted. Attention will now be required in the way of keeping down green fly, for the destruction of which I have found nothing to equal clean water vigorously applied with the syringe. In fact, if the syringe be used as it should be, green fly will not be troublesome; but if it should make its appearance and resist the syringe, it may be removed by dusting the growing points with Tobacco powder. At this stage, if room can be spared, I usually insert the pot containing the plant into a very large pot, (say No. 8 or 12), and fill up, keeping the top of the 48-sized pot on a level with that of the larger one; and as the breaks push out, these are pegged down by the aid of a few pieces of wire, an operation much more easily done now than later, besides running less risk of breakage than when the wood is allowed to set. They may remain in the 48-sized pot until about the last week in April (stopping in the meantime,

if necessary), when, if the plant has done well, it will be ready for its next shift into a 24 or 16-sized pot, according to its size. A word of caution is here necessary in order to warn growers against letting their plants remain a day after the roots have touched the sides of the pot. They should now be removed to a cold frame, taking care to cover well up at night and during cold winds, for although Chrysanthemums are perfectly hardy, they should be kept growing, in order to ensure a good bottom; in fact, it would be better to keep them in a greenhouse were it not for the sudden bursts of sunshine that occur about this time and the increasing warmth of the atmosphere, which induces the plant to become drawn, as it is called, an evil which I would most strongly impress upon the grower to avoid. About the end of May move the plants to the open ground; although, even then, if a little protection, such as that of a few Spruce branches, &c., be afforded them at night, they will be all the better for it. Plunge them about half-way up in a bed of coal ashes; set in the pots on a piece of slate, in order to keep out worms. The breaks as they grow must be stopped, and pegged down level with the edge of the pot. Some recommend the pot to be plunged in the ashes, right down to the rim, but if this be done, the foliage is liable to get splashed and dirty, and, therefore, the removal of some of the best developed leaves becomes a necessity. About the end of June, the plant will be ready for its last shift. The size of the pot in which it is to bloom will depend upon the growth which the plant has made; if very vigorous, use an 8-sized pot; if of medium growth, a No. 12 will suffice. The former size is required only in the case of very large specimens. The plant will now have acquired a pretty good size and its growth must be kept well pegged down. The pegs which I generally use are made of pieces of bundle wood, such as that employed for lighting fires, sharpened to a point, a stout piece of wire being inserted in the other end, and bent over to form a crook (fig. 1), which will keep the growth pegged down at any desired height. About the second week in July the plants should be stopped for the last time; and, as this is an operation of great importance, it should be done in a manner that will ensure an even and well-balanced specimen.

Pompones.

With these, the only difference to be observed is, that the later shifts need not be so large as those for ordinary kinds, and that the last stopping may be performed in the first week in August; with these exceptions is the mode of procedure with regard to both sections is the same. Now that we have got the plants into their blooming pots, and the last stopping has been performed, they will grow rapidly. They should be syringed vigorously, especially in the evening, and be watered overhead through a fine-roset watering-pot. Avoid the use of stimulants, as I feel convinced from experience that Chrysanthemums do not require them until the roots have begun to fill the pots, when very mild doses should now and then be administered. The secret of keeping the foliage healthy and of a deep green colour, consists in using judiciously clear house sewage, diluted in the proportion of one pint to a gallon of soft water. If the plants be kept well syringed with this, the cultivator will require nothing else. By the use of this liquid I have been able to keep the foliage of my plants in such a manner as to be the admiration of all who have seen it. The plant will now be getting into shape and making vigorous growth, which should be allowed to be somewhat higher in the middle than on the outside, in order to give it the form of a dome. As the flower-buds appear, they should be thinned, or what is termed "disbudded," that is, the middle or crown-bud of the four or five that form it should be left. Even beginners will have no difficulty in this matter, as the crown-bud, as its name implies, is always on the top, and the largest of the cluster. The time has now arrived for the grower to set about "shaping" his specimen. Of course he will be able to ascertain at a glance the size at which his plant will arrive; and, having in the meantime prepared a quantity of small sticks, made by splitting up builders' laths, and properly rounding them, he will proceed to train and tie. Some like their plants flat in appearance, but I am in favour of raising them in the centre, *i. e.*, a plant 4 ft. in diameter may be

2½ ft. high in the middle. This, in my opinion, improves the appearance of the plant. Having found the middle of the plant, the cultivator will stick and tie up a prominent shoot as a beginning, and this will be followed round and round, of course getting lower and lower, and by careful attention he will thus be able to clothe his specimen with healthy young branches down to the very edge of the pot. Of course, all the bare wood and sticks must be had, and all dead and decaying foliage removed, and, before tying is commenced, all suckers and blind growth must be removed. When the buds are forming is the time to commence the use of liquid manure, increasing its strength as they show colour, and continuing its use until the flower is fully developed. About the second or third week in October, plants treated as above directed should be removed to a cool greenhouse, giving them air on all favourable occasions, and taking care to avoid the use of fire-heat except when necessary to exclude frost. In 1871 we had a very severe frost early in November, and those who were able to give just sufficient warmth to keep it out made a much better display than those who had no such convenience; but still, as a rule, Chrysanthemums are best without fire-heat.

Pyramids.

These differ, as regards culture, from the preceding in having the bottom shoots left of sufficient length to form the base of the plant, and in having a strong shoot led up the middle so as to form a cone. The best-shaped pyramids are those grown on a frame, which is made by laying two cross pieces of wood on the top of the pot with a ring of iron wire outside forming a circle, to which are attached three or four upright wires, tied together at the top. This frame (fig. 2) may be attached some time after the final stopping, as soon as the operator has ascertained the size of the plant which his breaks are likely to make. The same course must be pursued with regard to Pompones. A fair size for pyramidal plants is 4 ft. through at base and 4 ft. 6 in. in height in the case of large varieties, and 2½ ft. at the base and 3 ft. in height in that of Pompones. Plants of these sizes, when well grown, are as near perfection as possible. I may here remark that after Chrysanthemums have once bloomed they need not be thrown away; on the contrary, they may be used again and again for many succeeding years if treated as follows:—When blooming is over withdraw the sticks and frame and cut the plants back to where the wood is likely to break, and if at this stage they can be assisted with a little warmth it will induce them to break more freely. When broken and the young shoots are about an inch in length shake the earth from the roots and reduce the latter, potting in as small pots as possible, and pursue the same course as has just been recommended. Plants that have been grown for blooms in a cut state may also be treated in the same manner; cut the stem down to 12 or 14 in. from the pot, taking care to remove all suckers. On this mode of culture full dependence may be placed; in fact, it makes the best plants. For those who do not care to confine their plants to a "single stem" the suckers need not be cut away.

Standards.

These owe their popularity to Woolwich and its neighbourhood. The plant which is to form a standard having been struck as early as possible, should be kept growing until it has reached 2½ or 3 ft. in height in the case of large-flowered sorts, and between 2 and 2½ ft. in height in that of Pompones. Having reached these heights, they should be stopped in just the same manner as has been recommended in the case of dwarf specimens, taking care to keep the breaks well down or "goose-necked," as it is technically called. They should be shifted and dealt with exactly as has been already described, and they should have the hood (fig. 3) put over them, as by getting it on early the trees can be attached to the wire-work, thus saving the necessity of having long strings from the pot to the break. The size of the hood which I generally use is 20 in. wide by 16 in. high for large-flowering kinds, and 16 in. by 12 in. for Pompones. If the grower can cover more space, of course, he will make a larger hood, but for general purposes he will find these sizes quite large enough, for it is much better to have the hood well covered than gaps here and there in the foliage. I may here mention

that I am decidedly in favour of disbudbing Pompones as well as large-flowering varieties, for, when not disbudbed, the three or four blooms on the truss get crowded, and do not show themselves off to the same advantage as a single crown-bud does.

Cut Blooms.

Although plants are admired—and justly so—at exhibitions, yet they certainly yield in point of interest to cut blooms. The production of large blooms of good quality is an easy task, and it is surprising that we do not see more of them, for with but little skill and a small outlay, grand results may be obtained in the following way; and to business men, employed in towns all day, I can especially recommend its adoption. Cuttings should be obtained about 2 in. long (I find those that are short make the best plants), and inserted round the edges of small pots, and put out of the reach of frost until rooted, when they should be shifted separately into small 60-sized pots and kept in a cold frame, changing them from time to time until the final shift, which should take place between the 24th and end of June; in the meantime, they should be allowed to grow uninterruptedly without stopping. They should be set out in the open air on slates, in the full blazing sun, and not plunged. This will entail a

Fig. 3 (trellis for standards). Fig. 2 (trellis for pyramids).

little extra labour in watering, but it will ensure perfect ripening of the wood, without which it is useless to look for fine flowers. They should be liberally supplied with water that has been exposed to the action of the sun; or, failing this (as it is not always convenient to do so), the hardness of the water should be taken off by the addition of clear house sewage, in the proportion already recommended in the case of specimen plants. When the buds begin to show colour, and not before (except in the case of a plant that is losing its leaves, thus indicating abundance of roots in the pot), liberal doses of manure-water should be given till the blooms are developed. Growers need not be afraid of using this liquid in a strong state, as the Chrysanthemum is a gross feeding plant. I would recommend a little discretion to be used as regards the manner of giving it to them, as some varieties, such as Eve, Mrs. Halliburton, &c., are robust growers, and require a great deal of it; while others, such as Little Harry, Beverley, &c., will fail to make anything like the growth of those just named. Some may say that the use of liquid-manure should be discontinued when the bud shows colour; but, from my own experience, and also that of some of our best exhibitors, I feel certain that the flower needs such support when making its petals. The kind of reasoning adopted by some writers amounts to this, viz., that as soon as the plant

has abstracted all nutriment from the soil given to it at the last shift, we should discontinue giving liquid-manure; whereas giving liquid-manure after the soil has lost its good qualities makes up for the deficiency. Your readers will, therefore, I feel certain, see the advisability of adopting the course which I suggest. I must not omit to mention the necessity of removing all suckers that arise from the bottom of the plant, as these, if allowed to grow, will absorb all goodness out of the soil, to the detriment of the flowers.

Soil, Potting, and Dwarf Plants.

The compost which I employ consists of good loam in a rough state not stacked too long before it is used, as I prefer it rather fresh, added to half its bulk of well-decayed manure, and a very free addition of road grit or sand. The pots should be well drained with crocks and broken oyster shells, and, in the case of specimen plants a few pieces of charcoal, about the size of Walnuts, will be a beneficial addition, although I warn your readers to be sparing in its use, inasmuch as a little of it benefits plants, but an overdose causes them to shed their leaves. Those who have low-pitched houses will find the following mode of growing plants in a dwarf state very convenient. Supposing the plants to be growing freely, and had received their last shift prior to the blooming pot, about the first week in June take a sharp knife, and cut them down to as many eyes as blooms are required. By the time they have pushed shoots an inch long they will be ready for their final shift, and by following the same routine as already recommended, grand results will follow, and the plants, which will range from 1½ to 3 ft., will make fine subjects for conservatory decoration. The blooms will not suffer either in quality or size from this (what may appear to many) barbarous treatment. A very few will require cutting down some days earlier than the others; but this is a matter that the grower will learn by experience. In the event of the grower aiming at showing his blooms at the forthcoming exhibition, with only two or three at their best, and doubtful of their powers of lasting, I unhesitatingly advise him to cut them and place them in water in a cool dark place; for this I find ginger beer bottles filled with rain-water excellent. From experience, I am able to affirm that blooms stand much better thus treated than when allowed to remain on the plant. Give air on all favourable occasions; but, if the blooms are not likely to be out by the day of exhibition, give the plants a thorough soaking of water, water the paths, and shut the house up close. This will have a magical effect in hastening the development of *Chrysanthemum* blooms, without the attendant risks of fire-heat, such as causing them to reflex, &c. Another good mode of retarding the bloom, and one which I have seen tried occasionally, is allowing it to hang down in such a manner that it faces the mould; this, it may be added, has also the desirable effect, especially in the case of varieties with long petals, such as Prince of Wales, Golden John Salter, and many others, of causing the back petals to incurve properly, thus giving the blooms the appearance as represented in the engraving.

Incurved *Chrysanthemum*.

Select Kinds.

The following is a selection of some of the best varieties, both for cut blooms and for specimens. Many kinds are recommended for specimen growing that are really not worth the time spent upon them—they are either deficient of foliage, or the wood is too snappish, or they do not grow freely enough to form good, well-grown plants. For dwarf specimens, Mrs. Geo. Rundle, the finest white, and its straw-coloured sport, Mr. George Glenny, stand pre-eminent in all good qualities necessary for the purpose; Guernsey Nugget, primrose-yellow, can be confidently recommended on account of its free growth, being short-jointed, and possessing one of the best of habits; Hereward, purplish-rose, is also very fine, and can be grown with an assurance of blooming satisfactorily; Prince of Wales, purplish-red, although rather long in the petal, is nevertheless one of the best growers and bloomers, and should be grown in the most select collection; Mr. Brunlees, red, tipped with gold,

is also very fine and attractive, and cannot fail to please; Jardin des Plantes, intense bright yellow, is desirable on account of its brilliant colour, and the blooms incurving without the least help; Lady Harding, bright rose, with silvery back petals, is one of the most chaste and beautiful in the class to which it belongs, and one which can be most strongly recommended, as it has all the qualities necessary for a good specimen. With the exception of Jardin des Plantes, all the foregoing will answer for standards, and can be well recommended for that purpose. In addition to the above-mentioned varieties, Hetty Barker, pearly-white; Venus, lilac-peach; Dr. Sharp, crimson-red; Lady Talfour, pinkish-rose; Miss Hope, pink; Lord Derby, bright red; Mrs. Halliburton, creamy-white; Annie Salter, soft yellow; Hermione, white, tipped with faint pink; Pink Perfection, delicate pink; Orange Annie Salter, orange; are all kinds that can be strongly recommended for dwarf specimens and standards.

In the Pompones class, La Vogue, bright gold, is very effective; when developing itself, it has bright red tips, which give it a striking appearance. This is one of the best of its class, and one which should be grown in the most limited collection, as should also Madlle. Martie, the pure white; President (sometimes called President Decaisne), reddish-rose; Mr. Astie, yellow (Anemone), one of the very best, both in habit and flower; St. Michael, bright yellow, an old variety much neglected of late, but now beginning to be appreciated as it should be, being one of the very best and freest in its class. These have all rather large flowers, and should be disbudded to be seen to the best advantage. They are, without doubt, the very best Pompones in existence. Antonius, bright gold, is likewise very fine. I should have included this variety among the foregoing, but it is somewhat weak in the neck, a quality condemned by some, although others prefer seeing it, as they consider that it gives the bloom a natural appearance; but even this weakness can be obviated by twisting some wire round the stalk. Calliope, red-brown, is a kind both novel and striking, although rather sparse as regards foliage; Salomon, cherry-red, is rather stubborn in respect to training, but is desirable on account of

be grown in the most limited collection, as should also Madlle. Martie, the pure white; President (sometimes called President Decaisne), reddish-rose; Mr. Astie, yellow (Anemone), one of the very best, both in habit and flower; St. Michael, bright yellow, an old variety much neglected of late, but now beginning to be appreciated as it should be, being one of the very best and freest in its class. These have all rather large flowers, and should be disbudded to be seen to the best advantage. They are, without doubt, the very best Pompones in existence. Antonius, bright gold, is likewise very fine. I should have included this variety among the foregoing, but it is somewhat weak in the neck, a quality condemned by some, although others prefer seeing it, as they consider that it gives the bloom a natural appearance; but even this weakness can be obviated by twisting some wire round the stalk. Calliope, red-brown, is a kind both novel and striking, although rather sparse as regards foliage; Salomon, cherry-red, is rather stubborn in respect to training, but is desirable on account of

its fragrance; Bob is an old, rather shy, blooming kind, a fault compensated for in some measure by its beautiful foliage and colour; Astrea, an Anemone variety, has when in bloom a fine appearance; Mrs. Hutt, chestnut-red, is well worth growing on account of the variety which it affords. This and one called St. Thais are much alike; Trophée, silvery rose, is not so much grown as it deserves to be, for it is certainly one of the most elegant Pompones in cultivation. It is not quite so large as some of the foregoing, but this is amply compensated for by its good qualities; La Sultana, rose colour, is another of the neglected sorts, but one which can be recommended. The varieties of Cedo Nulli, white, lilac, and golden varieties, are still indispensable, especially for beginners, being easy to grow, and never failing to bloom satisfactorily. For small plants, Bijou de l'Horticulture, General Canrobert, Louisa, Miss Julia, Model of Perfection, Rose d'Amour, and the White and Rose Trevena, will be found of service.

As regards cut blooms, I propose to treat them as if making a selection for the most experienced grower, but will mark those that I recommend for beginners thus *. My reason for so doing is that many of our best flowers belong to what is termed the Queen section, *i.e.*, those having very long petals, which to the novice would be found somewhat embarrassing; the varieties marked will be those that incur perfectly without aid. Queen of England, blush, its sport, known as Golden Queen of England, and its synonym, Emily Dale, I cannot recommend, as they are not to be depended upon; Alfred Salter, delicate pink; Empress of India, pure white (synonyms, Lady St. Clair and Mrs. Cunningham); and Golden John Salter, rich clear golden amber. The foregoing flowers are characterised by length and breadth of petal, perfection of build, and for requiring vigorous treatment to have them fit for exhibition; but, when blooms of good quality are staged, they are so striking as to be worth all the trouble required to obtain them. Jardin des Plantes, *yellow, is one of the best of its class, and one which can be depended upon; it makes a striking exhibition flower. John Salter, very fine in build of flower and breadth of petal, requires vigorous treatment; White Globe, pearly-white, has good flowers, but unfortunately they do not last; Prince Alfred, *a rosy-red, is one of the most reliable blooms we have; Princess of Wales, pearly-white with pinkish shade, when well grown, is a grand flower, but apt to come somewhat flat; even then, however, it is a fine flower, but when the centre is well elevated it is almost without a rival—its synonym is Beauty of St. John's Wood; Isabella Bott, pearly-white, is somewhat in the way of the former, but not quite so shaded; Empress Eugenie, rosy-lilac, is a very chaste and grand flower when well grown, but one which the beginner will find some difficulty, from the fact of its centre being overcrowded; therefore, when about half grown the centre petals should be pinched out with the finger and thumb so as to induce it to throw out large outside petals, and, thus treated, it makes one of the best and handsomest flowers. Cherub, *dull amber, suffused with pinkish shade, is a very fine conical flower of large size and perfection; Mrs. Brunlees, *red, tipped with gold, is a fine flower, and very telling on account of its high colour; Prince of Wales, purplish-red, is very distinct in colour, and occasionally somewhat flat, but a flower to be depended upon, and one which is indispensable in a collection. This flower is all the better if hung down during development, as the back petals are so very long that the weight of the bloom causes them to fall down, giving it a somewhat ragged appearance; but I advise all to grow it. Rev. J. Dix, red, with glow of peach, centre shading off to orange, is a very fine flower, but unless grown well, it shows a badly notched petal—a fault that would condemn it on an exhibition table; if grown well, however, the edge of the petal is as smooth as that of any variety grown, and then it is a gem. Princess Teck, *an immense white kind, full of quality, possesses all the points necessary for an exhibition flower, and is one that I can most strongly recommend; also Hero of Stoke Newington, lively pink, a sport from it; Lord Derby, *bright crimson-purple, one of the most constant and perfectly incurving flowers; Mrs. George Rundle, *pure white, one of the finest of decorative Chrysanthemums, and one which can be strongly recommended. Its straw-colour sport, Mr. George

Glenny, *is equally to be commended. Lady Hardinge, *bright silvery rose, is a grand and striking flower, which even the smallest collection should contain; Golden Eagle, *Indian red and orange, is a very constant flower, broad and blunt in the petal, and perfectly incurved in the way of General Slade, *which is another of the same shade of colour, and both are very useful varieties for beginners. Nil Desperandum, *dark red, is very constant and one of the best; Golden Dr. Brock, *clear primrose-yellow, a very fine (although somewhat flat) flower, one of the prettiest and most delicate, and can be strongly recommended. Pink Perfection, *rich rose; this is a very beautiful flower, and one possessing a good warm colour, and, in addition to its merits as a show flower, is very useful for conservatory decoration, as it possesses the most handsome foliage of the whole class to which it belongs; its synonym is Miss Mary Morgan. Barbara, orange amber, is a very plump conical flower, but apt to become notched in the petal; the best way to obviate this is vigorous treatment. It is a kind with which we cannot dispense, as its colour is so striking. Plutus, dull amber, a remarkably fine built medium-sized flower, incurving perfectly, and not difficult to manage; Antonelli, *orange shaded, with a tinge of salmon, is one of the best and most constant flowers we have, and one very dwarf in habit; its blooms are not quite so large as those of some, but they are perfection as regards shape and finish, thus fully compensating for lack of size; Princess Beatrice, *rich rosy-pink, is very distinct on account of its long and thin-clawed petal; it is very conical, of the best build, and generally to be depended upon, apt to make slender or weak growth, and requires a little coaxing to bring the flower to perfection; Abba Pasaglia, *amber, is a very constant flower, finely incurved, and of easy growth; Beethoven, and its synonym, St. Patrick, are certainly very distinct in colour, but nothing can compensate for its notched petal, and all the cultural skill hitherto has not been able to eradicate it; if not fit for exhibition, I would recommend a few plants of it to be grown for its distinctive colour; but never, if possible, put it on a show board. Enamel, blush, is a very nice incurved flower, of perfect build and appearance—not to be depended upon, but when obtained in good condition it is worth all the trouble taken with it. Venus, *lilac, is one of the most constant and superb medium-sized flowers which we have, and I can strongly commend it to beginners; its colour is very clear, and the flower lasts a long time in perfection—a very desirable quality. Novelty, blush, a large conical flower, wants good cultivation to induce it to attain perfection; Ewe, *sulphur white, and Mrs. Halliburton, *creamy white, are very similar in style, although perfectly distinct in colour; they must be grown in the strongest possible manner, and are to be classed as two of the most beautiful and chaste varieties in cultivation; I cannot too strongly impress upon growers the necessity of having these flowers. I have, perhaps, said enough with regard to exhibition flowers, but still there are many other valuable sorts that must not be overlooked, such as Sam Weller, Aureum multiflorum, *Lady Slade, *General Bainbridge, *White Venus, *Orange Perfection, Mr. Gladstone, fine chestnut red, very distinct from every other kind in cultivation; Guernsey Nugget, *primrose-yellow, very large, but insufficient as to quality for a really first-class board of flowers; Beverley, *and its sport Golden Beverley, *much recommended; Oliver Cromwell, *and its synonym, Mr. Evans, chestnut red; Dr. Brock, George Peabody, Gloria Mundi, *Iona, Jenny Lind, Lady Russell, Laurinda (a grand purple flower), and Princess Mary, are all good.

A few of the best of the large-flowering Anemone Chrysanthemums are as follows, *viz.*, Lady Margaret, white; Empress, clear lilac; Prince of Anemones, reddish lilac, one of the most constant; King of Anemones, cherry-red, very distinct; Madame Goderau, or its synonym, Geo. Hoek, white; Louis Bonamy, rosy-lilac; Acquisition, reddish-lilac, with yellow centre, very fine; Gluck, a very fine and bright yellow, recommended as one of the best; marginatum, blush, with rose centre, good; Princess Louise, somewhat in the way of Prince of Anemones, good; Sunflower, sulphur, very distinct; St. Margaret, brassy-amber; and Mrs. Pethers, rose, good. The foregoing will be sufficient for any ordinary collection (although

there are many others very fine, as most schedules allow duplicates to be shown on a board of twelve. The beginner will be able to manage all the foregoing, as well as those included in the next section, which consists of the class known as Anemone Pompones. They are kinds that can be specially commended for decorative purposes, as they are very easy to grow; they may be successfully treated in 24-in. sized pots, using the compost recommended for large-flowering varieties. They may be stopped once or even twice with satisfactory results. The following are among the best, viz., Rose Marguerite, rose, very large and fine; *Regulus*, cinnamon brown, a kind with a remarkably fine disc, and very even guard petals; Mr. Astic, pale yellow, one of the most perfect flowers in cultivation; *Antonius*, bright gold, rather wanting in fullness of guard petals, a fault, however, amply compensated for by its superbly quilled centre; *Astrea*, silvery rose, a very beautiful and chaste flower; *Astarte*, brassy-amber, very distinct and beautiful; *Perle*, deep rose, a very large and good flower; *Zobeide*, light rose, one of the best; *Miss Nightingale*, white guard petals, with gold centre, very fine; *Madame Montels*, paper white, with gold centre, one of the very best, and one which should be in the most select collection; *Jean Hachette*, very late, often blooming in December and January, the largest of the section, a very massive flower, recommended as being perfect; *Firefly*, rather small, but very striking, in consequence of its bright scarlet and gold centre; *Dick Turpin*, magenta and gold, and very pretty, but too small for exhibition; and *Marie Stuart*, very chaste, but wanting somewhat in fullness, otherwise the colours (bluish-lilac and pale yellow) make it very distinct. The above will be sufficient, unless a very large collection is required, although of course it does not embrace all the varieties that may be considered good. Some of the Anemone kinds have the habit of developing ray petals among the centre; if this occurs they can be easily removed with the finger and thumb.

To make the series of selections complete, I append a few flowers known as reflexed, *i.e.*, flowers showing the inside of the petals. The colours of these varieties are much more brilliant than those of the incurved; but, of course, they lack the high finish of that section. They are very useful for conservatory decoration, and much to be desired. *Chevalier Damage*, bright gold, undoubtedly the finest coloured *Chrysanthemum* in cultivation; *Dr. Sharpe*, crimson red, also very fine colour; *Julie Lagravere* and *Progne*, velvety red, both very fine; *Annie Salter*, clear yellow, when grown well a perfect gem; *Cassy*, red suffused with peach; *Christine*, bluish; *Felicity*, a good cream-coloured flower; *Orange Annie Salter*, a sport from *Annie Salter*, and one possessing all the good qualities of that desirable variety.

CULTURE OF ACHIMENES.

MANY of the present race of *Achimenes* are garden hybrids, the result of crossing the different species introduced from Jamaica and South America. *Achimenes* have many properties that commend them to the general cultivator, amongst which are the ease with which they may be grown, their long-continued blooming, and also their ability to bear when in flower a considerably lower temperature than that of a stove;

their suitability for conservatory decoration during the summer season, when the majority of plants have ceased flowering, makes them valuable for using in that way. They rest through the winter, during which they should be kept in dry material, either sand or soil, and may be put away anywhere in a dry place where the temperature does not fall below 50°; in one much lower than this they are not safe for any length of time, as, if kept too cold, they decay. Although, as I have said, they last in flower for a considerable period, still it is well to start them into growth at different times, so as to have a succession. If some be required early, say in June, a portion should be started about the end of February, and a second lot, say in a month or five weeks afterwards. Prepare some ordinary seed-pans, proportionate in size to the quantity of each variety to be grown, put in the bottom of them a few bits of crocks, and on these place the soil; that for starting the roots in should be of a light character. They will thrive in either peat or loam, mixed with leaf-mould and rotten manure, to which add sand according to the description of soil used.

As these pans are merely used for starting them into growth, the soil, as I have already said, should be of a very light character, so that they may be moved from it without injuring the young roots, a circumstance that will occur if material of an adhesive nature be employed. If peat of a fibrous description be used, add one-fifth of leaf-mould; if loam, put an equal quantity of leaf-mould; fill the pans two-thirds of their depth with the soil, then place the roots 1 inch asunder evenly upon it, and over them put 1 inch of soil, which should be in a medium condition betwixt wet and dry. Place the pans at the coolest end of a stove; and if this will afford them a night temperature of 65°, do not give any water until the roots have commenced to grow, unless the soil has obviously got too dry, or they may rot. As soon as the shoots make their appearance above ground, set the pans as near the light as possible. If there be a shelf overhead close to the glass, that is the best position in which they can be placed. Do not keep them in a dark situation, or they will become drawn and weak, a condition that spoils them. When the young shoots are about 3 in. in length they should be moved into their flowering pots, and now it must be determined what sized plants are required.

They may be placed in 7-in. or 8-in. pots, or in such as are up to 12 in. or 14 in. in diameter, according to the purpose for which they are wanted. A medium size in most cases will be the most useful; drain the pots well, add to the peat or loam, whichever they are to be grown in, a moderate quantity of rotten manure and leaf-mould and a sprinkling of sand; press it moderately firm, and fill the pots up to within 2 in. of the rim; then put in the plants about 2 in. apart, and place an inch of soil over the roots, pressing it slightly down; re-place them as before in a light situation. As the days get longer the temperature may be increased 1° in the night, and proportionately higher in the day, giving a slight shade in very bright weather, with air in the middle of the day. As growth advances, a neat stick, proportionate in length to the strength of the variety, should be put to each, to which let it be tied so as to make the whole shapely. As the soil becomes filled with roots a plentiful supply of water should be given, and the plants should be freely syringed overhead every afternoon. When the flowers

Anemone-flowered *Chrysanthemum*.

are fully formed, and before they begin to open, if intended that the plants should be moved to a cooler house when in bloom, they ought to be gradually inured to the change by placing them where they will get more air, with, if possible, a little lower temperature, without subjecting them to too great a change all at once, as, if checked, they sometimes do not open their flowers freely. When in bloom, do not let them suffer from want of water, or the flowering will be soon over. When done blooming, set them in the corner of a house where they will be kept moderately warm, and supply them regularly with water, as, if neglected, either by a deficiency of this or by being set where they are too cold, they form very poor roots for the ensuing year. Attend to them in this way until the tops gradually die down, when the roots may be either allowed to remain in the ball of dry earth by setting the pots in a place with a suitable temperature, as already recommended, or they may be shaken out and put in paper bags in a little dry sand, so as to keep the air from them.

Achimenes make excellent basket plants for suspending in conservatories or similar places. When wanted for use in this way, the baskets should be made of galvanised iron, proportionate in size to the place they are intended to occupy. They should be first lined with 2 in. of clean Moss, upon which put the same depth of crocks or broken charcoal—the latter is much the lightest—fill up with soil, as in the case of pots, and plant similarly. When necessary, the outside shoots may be tied to sticks in a horizontal position over the sides of the baskets, the inner ones being tied so as to furnish the upper surface, and make the whole shaped. Managed in this way, they are very effective. Plants for successional flowering require treating similarly in every way, except starting into growth, as already said, somewhat later. Any variety that happens to be scarce may be increased readily from cuttings made from the young shoots in lengths of two or three joints, cutting them at a joint to form the base; insert them in pots or pans filled with half peat and sand, place them in heat, keep them moist, and cover them with a propagating glass. The following are all good kinds, viz.:—*Ambroise Verschaffelt*, a fine white sort, with the centre marked with dark rays; *Aurora*, scarlet, with a yellow eye; *longiflora alba*, white, slightly marked in the centre; *longiflora major*, a very fine blue sort; *Mauve Queen*, a very fine large-flowered kind; *Rose Queen*, purple and rose, with yellow throat, very compact in habit, and a profuse bloomer; *Pink Perfection*, magenta, shaded with violet, carmine eye; *Williamsii*, vivid scarlet; *Stella*, magenta, spotted with carmine, orange eye; *Firefly*, deep carmine, spotted with crimson, eye yellow. Achimenes are not so subject to insects as many occupants of the stove, although mealy bug will live upon them, and, when once they get affected with this pest, there is not much chance of removing it in any way but with a small brush and sponge, as the nature of the plants will not permit the use of any insecticide that will kill the insects. They are also liable to the attacks of red spider, which must be guarded against by a diligent use of the syringe.

T. BAINES.

A Beautiful Greenhouse Climber.—I have just been gratified by the sight of a very lovely house of delicate bloom afforded by a plant which every one who loves a fine greenhouse climber should grow—*Clematis indivisa lobata*. It was planted out in a border, and had overrun the roof, and bore (on March 13) the most profuse crop of blossoms I have ever seen on a climbing plant. The flowers are pure white, and have a brush of delicate stamens in the centre. Outside, and at a distance, the house seemed full of *Paris Daisy* in its densest bloom, but, on entering the house a profusion of flowers was seen below as well as above the foliage. This *Clematis* is not one having large saucer-shaped blossoms, but it more than makes up for this by the purity of its flowers and a habit of rare grace. The plant to which I allude is now in flower in a cool house at Bolesworth Castle, near Broxton, in Cheshire.—Y.

Bedding Plants in Moss.—The quantity of bedding plants now required render the potting off, as formerly, of each individual plant out of the question, and thousands, more especially *Geraniums*, are never put in either pots or boxes—the cuttings being inserted about 2 in. apart in the spaces occupied by Melons and Cucumbers in pits and houses, and about this time lifted and tied up in Moss with a handful of soil, after which they are set on the beds again and

kept moist until thoroughly established, when they are hardened off under any spare lights or movable covering, and are in better condition for starting into growth than those in either pots or boxes. If lifted in autumn for preserving through the winter, the ball of Moss will be found quite perfect, and if set closely together in a cool house, with a little soil shaken amongst them, they will make excellent plants the second season.—J. G.

The Polyanthus in the Greenhouse.—There are few plants more useful and showy when grown in pots for the spring decoration of the table than the *Polyanthus*, at the same time requiring so little trouble and attention. I find the easiest and most satisfactory way of growing it for the greenhouse is to sow the seed of a good strain in gentle heat any time from the middle of March to the end of April; the earlier sowing will of course produce the strongest plants, but the result will be satisfactory from the later sowing if the plants be properly attended to. When the seedlings are sufficiently strong prick off a portion, 12 in. apart each way, in rich soil on a north border. Should the weather be very dry, an occasional soaking of water will benefit them. The best should be taken up and potted in 6-in. or 7-in. pots towards the end of October, and plunged over the rim in ashes in a cold frame for the winter. Pick off the remainder of the seedlings in thumb pots, and, when strong enough, re-pot into 4-in. or 5-in. pots, using rich soil, then plunge them in ashes, where they should remain till there is danger of hard frost, under which circumstances, like those growing in the open ground, plunge them in a cold frame. I find the advantage of growing them as suggested, that those grown altogether in pots, being smaller and dwarfier plants, are more useful for the front of shelves or stages; the others will be stronger and more robust, and throw up their blooms higher and in greater profusion. *Polyanthuses* neither require, nor will they stand much forcing. Let me recommend anyone fond of our old-fashioned border flowers to give them a trial in pots.—J. E.

Nemophila insignis for Hanging Baskets.—In no way does this *Nemophila* appear to better advantage than when grown in a wire or other basket, and suspended from the roof of a greenhouse or conservatory during the spring months. It is scarcely eligible as a summer bedding plant (although its habit and colour are all that could be desired) on account of its somewhat transient character during hot dry weather; but it is exceedingly effective as a spring flowering bedding plant, and when intended for this purpose it should be sown early in August, and the portion of plants required for indoor decoration should be potted into small pots about the end of September or early in October, and placed in a cold pit or frame. About the beginning of November they should be transferred to their flowering pots, which need not be larger than 5 or 6 in., and the soil used should consist of light turfy loam and about a fourth or fifth part of leaf-soil. The plants should then be placed upon a shelf near the glass in any ordinary greenhouse temperature. Thus treated they will generally begin to show flower about the middle of February, when they may be placed in wire baskets and have their pots neatly surrounded with green Moss and suspended from the roof of a light conservatory or other structure. If well supplied with water they will soon become very ornamental, and will continue to flower until the beginning of May or longer if desired, producing in profusion their beautiful pale blue white-eyed blooms, larger and in every way in better condition than they generally do in the open air. Other varieties of *Nemophila* may also be grown in a similar manner and with equally good results.—P. GRIEVE, *Culford Hall, Bury St. Edmunds.*

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Destroying Earth-worms in Pots.—Referring to Mr. Radclyffe's recent introduction to keep pots free from worms, a writer in "Moore's Rural," says—"We use hot water to kill earth-worms—as hot as can be endured by the hand. This kills them instantly, and we have never known it to injure the roots of the most delicate plants. The experiment is easily tried."

Forcing Irises.—"R. H. B." (see p. 246) speaks of the Persian Iris as the only one that will bear forcing. Has he tried *I. reticulata* and *I. uberosa*? I potted *I. reticulata*, *I. persica*, and *Hyacinths* and other Dutch bulbs, at the same time, and *I. reticulata* was the first to flower by a fortnight, and it produced finer flowers than those usually found on its out-of-doors. Like *I. persica*, it is very sweetly scented. *I. uberosa* also forces well, and flowers freely, but it is more singular than beautiful.—R. A. O. *Fulham.*

Propagating Alternantheras.—The most expeditious way of striking a large stock of these is to put about 2 in. of fine soil covered with sand into the bottom of ordinary cutting boxes, and insert the cuttings as thickly as possible, with a large square of glass over the top. In a house or pit, such as that devoted to Pines, or over the duct or hot-water pipes of any forcing structure, they strike root in a few days, if shaded during bright sunshine. As soon as rooted, the glass should be removed by degrees, and the plants gradually hardened off.—J. GROOM.

THE LIBRARY.

FORESTRY AND POETRY.*

THE grandeur and beauty of forest trees have attracted the admiration of poets in all ages, and some of their most striking lines have been inspired by trees, from the Cedars of Lebanon to our own giant oaks of Sherwood, Windsor, and Arden. It is well that foresters and horticulturists in general should know and appreciate the noble thoughts which poetic genius has allied with the objects of their study and culture. Such knowledge must necessarily tend to elevate the character of their pursuits, even in their own estimation, when feeling that they share the appreciation of their noble calling with the most highly-gifted minds of a long series of ages. No landscape-gardener could, for instance, read many of the exquisite lines in Goethe's "Love as a Landscape-Painter" without becoming prouder of his own work, feeling as he would that he is a maker of real landscapes, which ought, if he combine sufficiently skill and genius, to surpass the very best that can be done with pigments on canvas. It was, therefore, a happy thought, in so far as the horticulturist is concerned, to gather together in a chronologically arranged series, a selection from the poets of all ages of passages which have immediate reference to tree-grandeur, to general woodland scenery, or to ancient methods of forest, orchard, or garden culture. Something after this kind is the selection furnished in a volume entitled, "Forest and Woodland Scenery, as described in Ancient and Modern Poets," by William Menzies, &c. The selections, which are acknowledged to be made from well-known translations, if not always the very best that might have been chosen, form a very interesting series of passages bearing upon this subject, as may be seen by the following citations. Some of the most striking, if not the earliest poetic, allusions to the impressive grandeur of trees occur in Biblical literature; and the magnificence of the Cedar is, above all other trees, dwelt upon with the greatest admiration by the Hebrew poets. From the earliest time these lordly trees were chosen as emblems of greatness, beauty, and majesty; and when the wisdom of Solomon was extolled by his contemporaries, it was said that "he spake of trees, from the Cedar tree that is in Lebanon, even unto the Hyssop that springeth out of the wall;" and that his knowledge of their culture was as wide as proved by the recent researches of Ewold, who informs us that he made gardens, vineyards, and pleasant parks around Jerusalem. Our space does not admit of citing even a few of the various fine passages referring to the Cedar which occur in the Bible, but those who in reading them feel their beauty may satisfy themselves of their appropriateness and accuracy by comparison with some of the grand specimens of the trees themselves to be found in English parks and gardens, the oldest of which is in the garden of the old palace at Enfield, which is now 200 years old, and 16 ft. in circumference.

Homer, the greatest of the poets of classical antiquity, has bequeathed to us many magnificent lines, in which in a few terse but grand Greek words, he describes the majesty of the giants of the forest with unerring accuracy and force. How finely, for instance, in the Iliad, he converts into a noble simile of the meeting of Greek and Trojan in the shock of battle, the storm-wind that

Howls in the branches of the lofty Oaks.

And how accurate is his knowledge of the habit and most favourite habitat of the Poplar shown to be, when he refers to

"—some tall Poplar, grown in marshy mead,
Smooth-stemmed, with boughs up-springing toward the head."†

While the *Odyssey* contains more frequent and more extended passages, descriptive of forest and woodland scenes. His near contemporary, Hesiod, in the most ancient of known poems, which treat especially of forestry and agriculture, has combined instructions to the forester, the shepherd, and the ploughman, with a poetic grandeur of style in the treatment of the subject that rises, not unfrequently, to rivalry with the greater Homer himself.

The eminent Greek tragedians, *Æschylus* and *Sophocles*, have left us in their great dramas magnificent glimpses of what they might have done in Nature-painting had the character of their works permitted. In the "*Antigone*," of *Sophocles*, we get, probably, the origin of the well-known fable of the Heed and the Oak:

Then see'st the trees that bend before the storm
Save their last twigs, while those that that will not yield,
Perish with root and branch;

and how sweetly he describes a flowery dell in one of the *Choruses* of *Œdipus at Colonus*:

* "Forest Trees and Woodland Scenery, as described in Ancient and Modern Poets," by WILLIAM MENZIES, London: Longmans, Green, and Co., 1875.

† Lord Derby's Translation.

And there, beneath the gentle dews of Heaven,
The fair Narcissus, with its clustered bells,
Blossoms over, day by day—
Time-honoured wreath of mighty goddesses;
And the bright Crocus, with its leaf of gold.*

Theocritus, Apollonius Rhodius, and other Greek poets have left many passages descriptive of natural scenery other than those cited by the compiler of the present selection, and similar passages of great beauty might be selected from the works of other Greek poets not noticed by Mr. Menzies, who, after Apollonius Rhodius, passes at once to the Latin poets.

Among Latin poets, the first cited in chronological order is *Lucretius*, whose great poem is full of noble passages, in which he attempts to analyze the forces of Nature, and solve those problems respecting animal and vegetable life, which still remain as mysteries of our philosophy; though Mr. Menzies informs us that the puzzled *Lucretius* might have found his difficulties solved if he had been fortunate enough to read a few verses in chapters iv. and v. of *Æsdras*. The *Georgics* of *Virgil* are so full of fine descriptions of natural objects, and his descriptions of the practices of the agriculture, forestry, and the horticulture of his time are so very complete and numerous, and, notwithstanding certain superstitions, so accurate, that they should be carefully read as a whole by every educated horticulturist; while in the *Æneid* picturesque descriptions of forest scenery occur very frequently, as when *Æneas*, for instance, in his visit to Hades, saw, in "the realms of tranquil bliss," the transfigured Shades reclining in the midst of groves of fragrant Bay trees, and wandering among

Green spaces folded in with trees,
A Paradise of pinesances.

Next comes *Horace*, with his passionate love of rustic scenery, so felicitously described in a thousand graceful and fanciful passages, as when he tells us of his simple ambitions in the following charming couplet:

This used to be my wish—a bit of land,
A house and garden with a spring at hand,
And just a little wood—the gods have crown'd it
My humble vows: I prosper and abound.

A few selections, not quite the best that might have been selected are then given from *Ovid* and *Lucan*, and the compiler next passes to the Italian and German poets—*Dante*, *Ariosto*, and *Tasso* being the only Italians whose works are quoted, while in the German galaxy only *Goethe* and *Schiller* are laid under contribution. The English series of citations commences with *Chaucer*, followed by *Shakespeare* with his glorious gift of that exquisite power of seeing and appreciating Nature which has never been equalled. *Milton*, *Dryden*, and *Thompson* succeed, from whose works some choice morceaux have been obtained, while *Pope* in his "Windsor Forest" is shown descending like a trained landscape gardener, and describing like a great poet. *Gray* and his famous "Elegy," *Cowper* with his love of trees and flowers ever floating through the network of the celebrated "Task" and other poems, and *Macpherson* with the grand touches of *Naturo-painting* in "*Ossian*," are next laid under contribution; and then comes *Burns* with his appeal to his master, the Duke of Athol—

Would then my noble master please
To grant my highest wishes,
I'll shade my banks w' low ring trees
And Bonnie spreading bushes.

The volume closes with some attractive snatches germane to the subject from poets of our own time, *Wordsworth*, *Scott*, *Byron*, *Longfellow*, and *Tennyson*, among which *Byron's* couplet to the Cedar—

Dark tree, still sad when other's grief is fled,
The only constant mourner o'er the dead.

And *Tennyson's* felicitous picture in word painting—

In the midst
A Cedar spreads his dark green inyers of shade.

The general selection is very acceptable as far as it goes, in spite of numerous clerical errors, such as "phantacies" for "phantasies," &c., &c. But what shall be said of the illustrations? The most far-stretching amenity of a reviewer cannot find words of praise. As the works of amateurs, they might fairly be considered in the light of praiseworthy productions of an elegant leisure by a circle of admiring friends; but an appeal to the public is a widely different kind of ordeal. Our great landscape painters, from *Constable* to *Vicat Cole* and *Millaud*, and many others, have presented us with such noble examples of tree study that nothing which falls very far below the high standard of excellence to which the public taste is now raised can be even silently tolerated, especially in an expensively got-up volume on the poetry of trees and woodland scenery, professing to be illustrated chiefly from the magnificent forest scenery of the royal domain of *Windsor*, which contains some of the grandest

* Plumtree's Translation.

trees in Europe. Only to particularise a few, let us take first the representation of the grand tree known as "Queen Victoria's Review Oak." There is in this attempt not a single truly characteristic feature of the tree present. Neither the sturdy and massive grandeur of the trunk, nor the infinite ramifications of the great arms, nor the garled intricacies of the secondary branches are there. The peculiar kind of oaken majesty to be found in no other forest tree is not there, either in the stately grandeur of the general form, or in any of the details, while the execution is in every respect faulty, the touches representing foliage being as broad and heavy in the uppermost branchlets as in the lower portions of the tree, while the general handling of the foliage is of that conventional, flabby kind that was taught in ladies' schools when our grandmothers were little girls. In short, the style both of this and, indeed, the whole of the illustrations, is feeble and old-fashioned to an inconceivable degree in an expensively got-up volume in the present day. The weakness of treatment of the "Cedar at Maturity," at Belvedere Wood, is equally conspicuous, and seems like a painful bathos in face of the grand quotation from Ezekiel. Yet any one knowing the character of a Cedar at maturity, and having seen the reality at Oatlands, Virginia Water, or elsewhere, may imagine that the features, so feebly indicated in the present illustration, might actually be such as those so strikingly portrayed by the Hebrew prophet, if the portraiture had been placed in abler hands. How completely is the grandeur of a solitary Poplar missed by the linner in the representation of the tree at Upton. The Plane at Bagshot is a still more conspicuous failure. In the treatment of the venerable ruins of the most ancient of the Windsor Oaks, the washy poverty of handling is still more conspicuous. Any one who has seen Henshaw's magnificent portraiture (now in the Birmingham Art Gallery) of one of the grand old Oaks of the forest of Arden, a mighty ruin, treated with the firm crispness of an artist hand, could not, in a volume of so much pretension as the present one, look with common patience at the representation of "William the Conqueror's Oak," at Cranbourne, or that of the old Oak at the Prince Consort's Gate in Windsor forest. The grove of Yew trees in Belvedere wood is another sad failure. Neither in colour, appreciation of characteristic form, nor sombre grandeur and depth of effect, is the subject realised in the slightest degree; and the quotation from Wordsworth—"Beneath whose sable roof . . . ghastly shapes might meet at noontide"—renders the shortcomings of the yellowy-brown washy picture still more lamentable. The magnificent trees and groves of Windsor have yet to be described and illustrated, a task which can only be fitly executed by a pen-power as incisive as that of a Ruskin, and a pencil wielded by a hand equal to that of a Millais, a Cole, or a Graham. In conclusion it may be said of this handsome volume that it is acceptable as a whole, despite its shortcomings. It points the way to the subject as one worthy of our greatest artists, and also to a more abundant selection from the finest things that poets in all ages have said of mountain and woodland trees, in which passages from our garden poets, such as Mason and many others, should not be omitted any more than many from modern French writers, such as Delille and Lamartine, nor from the modern poets of Italy, nor even from those of Spain and Portugal both mediæval and modern, for there are as fine descriptions of natural scenery in the "Lusid" as in the "Inferno" or the "Genurusalemma."

H. N. H.

An Ancient American Elm.—A famous Elm tree, the pride of Boston Common, which is in its turn the pride of Boston, has just been blown down. This tree was one of the pet objects of the town. There have been many controversies about its age, but all the disputants admitted that it was very old. It figured upon the oldest map of the town, which was engraved in 1722, and there are those who hold that it was growing before the arrival of the first settlers in 1630. It was affectionately spoken of as "the oldest inhabitant of Boston." Sceptics declared that it was planted by a Capt. Henchman in 1670 to shelter the Ancient and Honourable Artillery Company which he commanded. This legend, however, was exploded by Dr. Warren, who printed a monograph of the Great Tree, and proved that it must have been 100 years old in 1722. 190 rings were counted in a branch broken off in 1860, which must have been considerably younger than the tree itself. It belonged to a species known as the "American or White Elm." Its first catastrophe was in the summer of 1832, when a gale partially broke off four of its larger limbs. They were, however, restored by careful surgery, bolted into their original places, and are said to have grown back into the tree again. In June, 1860, it lost a limb measuring 42 in. in circumference. Still it continued to grow. According to the latest measurement in 1860 the following were its proportions:—Girth at the ground, 24 ft.; at 3 ft. above it was 18½ ft.; at 5 ft. above, 16½ ft.

THE TOOL ROOM.

A PLACE for everything, and everything in its place, will save many hours of searching, many weary steps, and much vexation, every year. The tools should not only be in the room, but everyone in its place, where the hand may be always laid on it in a moment. For this purpose they should be hung up against the wall, and be neatly arranged. Nearly every tool can be hung on a spike or pin, or between two large nails. If hung perpendicularly, they will

occupy less room, and may be quickly taken down and replaced. Fig. 1 shows the manner in which the smaller tools may be thus arranged; and Fig. 2 exhibits the larger tools hung on the opposite wall of the same room. In order that each tool may be always in its place, the plan devised by Mr. Townsend Sharpless, of Philadelphia, is the best. Hang each tool in its position; then draw its outline accurately on the board wall with pencil or chalk; then with a brush

dipped in some dark coloured paint, make a distinct representation of the shape of the tool. These outlines will not only show where the tool should be put, but demonstrate at once if any have been left out of place. The consciousness that there is such a tell-tale in the tool-room, will stimulate any careless labourer to return everything which he takes out.—"Rural Affairs."

THE SOUTH KENSINGTON BREAKDOWN.

THE fact that certain notorious enterprises at South Kensington, which had their origin in the surplus of the Great Exhibition of 1851, are at the present moment in a condition of hopeless financial collapse, would not be in itself a matter of much consequence, if it affected only those who are immediately interested in these unfortunate projects. It happens, however, that a large sum of public money has thus been grossly misapplied, and that the Royal Commissioners, who are to a certain extent responsible for this discreditableness result, were appointed to act on behalf, not of private speculators, but of the community at large. It would seem, therefore, that the time has come when the Royal Commissioners should be called upon to render an account of the funds entrusted to them, and that the truth with regard to the various South Kensington Exhibitions should no longer be concealed with the connivance of the Government. The Duke of Edinburgh remarked the other day in reference to the Aquarium at Westminster, which has turned out to be merely a drinking-bar in disguise, that this precious institution was "a natural result" of the Prince Consort's benevolent projects; but those who have any genuine respect for the Prince's memory will probably hesitate to believe that he contemplated the results which have actually been produced, and will be disposed to think that the persons who are responsible for these results have formed a very

imperfect appreciation of the objects which he had in view. It was arranged that the profits realized by the first Great Exhibition should be applied to promote the general advancement of science and art; but it appears that the greater part of the fund has been bestowed on such projects as the Horticultural Gardens and the Albert Hall, and no one can pretend that science or art has profited by such an application of the money. The Horticultural Society has long ago abandoned even the pretence of doing anything for horticulture in its scientific aspects, and the Gardens have become a mere pleasure-ground for the use of neighbouring residents. As for the Albert Hall, it has never served, or attempted to serve, any purpose beyond that of competing in the ordinary way with the other concert-rooms and music-halls which are kept up by private enterprise; and it is difficult to see why it should be supported out of public funds. At the present moment both the Horticultural Society and the proprietors of the Albert Hall have absorbed a large part of the Royal Commissioners' resources, and are making no return. Indeed the one both in such a desperate condition that they are endeavouring to break the bargains which were originally made with their subscribers and to compel the latter to pay over again for privileges which have become a wretched mockery. It seems that the Society is at such a low ebb that its Journal has been discontinued, and it has now to depend for a "medium of communication between the Fellows" on the charity of the newspapers. Moreover, the prize list has been cut down to a merely nominal amount. The last resource of this distinguished body is now, it would appear, to stake its fortunes on a skating-rink, which must be admitted to be a very curious method of promoting science and art.

Under these circumstances, it is evident, says the "Saturday Review," that the Horticultural Society and the Albert Hall are in possession of public property on false pretences. The Horticultural Society holds ground from the Royal Commissioners valued at more than £100,000, and it is now heavily in debt to the Commissioners for unpaid rent. The financial position of the Albert Hall is at present surrounded with greater mystery; but it is clear that it is financially in a very bad way, since it has avowed its design of asking parliamentary sanction for a plan of levying a new tax on the unfortunate victims who have already purchased useless boxes and stalls at a high figure. If these enterprises had been carried out by the private speculators who are at the bottom of them in their own names, they would no doubt have been wound up long ago, and it is only by trading in a despicable manner on a respected memory, and obtaining the use of public money on empty pretences, that they have been enabled to prolong a scandalous existence. It is only just that, as far as possible, the public property which has thus been misapplied should be recovered for the use of the nation in some honest and respectable way, and that the cover of a Royal Commission should be stripped from institutions which would then be exposed in their true colours. Whatever may have been the original intention with which the South Kensington estate was taken up by the Commissioners, there can be no doubt that their management of it has practically taken the form of a mere building speculation. Whether it will prove to be for the public convenience that the natural history collections should be removed from the centre of Iowa to this remote suburb remains to be seen; but it can readily be understood that the scheme of concentrating museums and pleasure grounds on this spot is highly acceptable to the owners of house property in the neighbourhood, and this is the only class which has profited by the large expenditure which, by a gross abuse of authority, has been diverted from the true objects to which it was dedicated. It would be interesting to know what form of science or art is supposed to have been promoted by the ginnerack mansions of South Kensington. In a town which grows so rapidly as London it is always a pity that any piece of open ground should be swallowed up, and there might be reason to regret the conversion of the Horticultural Gardens into streets and squares. It is clear, however, that, whatever is to happen, the Horticultural Society has forfeited its right to the continued possession of this property, by its flagrant abandonment of the purposes for which it was pretended to be established. Some arrangement might perhaps be made between the Commissioners and the householders of the district for a lease of the ground; but in any case public money ought not to be applied to purposes of merely local convenience. The National School of Music is another offshoot of the same rank soil as that which has nourished the other Pungi. It enjoys distinguished patronage, and bears the usual delusive trade mark of science and art; but it should not be forgotten that it practically involves an attack on an older institution which, in the face of many difficulties, has done service of the highest value in the cultivation of musical taste and skill, and which an attempt is now being made to supersede, in order to provide further accommodation for the omnivorous Cole family, and a platform for the display of pushing professionals and distinguished patrons in search of a

popular reputation. There seems to be something in the atmosphere of this district which covers the institutions springing from its soil with a thick coating of parasitical incrustations. It is the great nursery ground of jobbery and humbug. From the early days of the Brompton Boilers a claptrap parade of enthusiasm for the promotion of science and art has been systematically kept up, with a view to diverting public money and patronage to this quarter for the benefit of an interested clique; and for the credit of public administration it is necessary that the abortive speculations which have resulted from this system should be cleared away. There might be no harm in such exhibitions if their character as commercial enterprises were candidly announced; but it is a scandal that such a system of mismanagement and imposture should be placed in any degree to the credit of public administration.

GARDENERS AND THE "SATURDAY REVIEW."

You have favoured us with a glimpse of what a writer in the "Saturday Review" thinks of us. From his stand-point it would appear that gardeners are the very essence of ignorance, conceit, and intolerance; men who require to be guided, on the one hand, like machines, and repressed and snubbed, on the other, as a social plague. Well, one can afford to disregard such a diatribe as that of which you have quoted only the mildest portions, but when we find editors of newspapers wholly devoted to gardening and gardeners sneering at us as a class of ignoramuses who do not know how to prune or train a tree, one week giving a portrait and autobiography of a notable member of our fraternity, and the next week publishing his name side by side with that of Dr. Kenealy in a mock committee of the Royal Horticultural Society, it is almost beyond the bounds of endurance. I have so often defended gardeners as a body from the cuffs of the latter class of writers, that I will pass them by on this occasion. I do not know where the reviewer has gained his knowledge of gardeners or his experience of their doings, but it is a pity that he does not make himself better acquainted with matters as they are in general, and not pick out exceptional cases. It cannot, I think, be disputed that I am capable of knowing as well, if not better than the "Saturday Reviewer" the position and relationship in which gardeners, as a class, stand to their employers and their gardens. Our reviewer joins lustily in the hue-and-cry against gardeners as having been the introducers of every vulgar fashion and feature that sur the fair face of Nature in garden, and represent them as being the masters of their employers, doing just as they like with their gardens—and bedding-out seems to be their unpardonable sin. Now, it so happens that I am now serving my fourth employer, and probably no gardener ever enjoyed more liberty of action in four successive situations than I have done; yet it also happens that in not one of these situations would I have considered it wise or safe to have altered one feature of the garden, or made an innovation of any sort without an order or a very distinct and unreserved sanction from my employer. And, so far as my knowledge goes of the position of gardeners in general, and perhaps it is a knowledge of them equal to that of the "Saturday Reviewer's," my experience and practice in this respect is a *fac-simile* of that of ninety-nine gardeners out of every hundred, and I shrink not from stigmatising any gardener who should attempt a revolution in the style or features of a garden, or who would attempt to be dictatorial to his employer, as foolish and blind to his own interest, to say nothing of the violation of duty and respect both for himself and his employer. With regard to the power which bedding-out—as it is vulgarly called—has gained in gardens, I can give you an illustration of how it came about in one case, and I know it to be the type of many more. In the year 1858 I took charge of Archerfield Gardens. The grounds at the old Castle of Dirleton were then a chaos of shrubs, herbaceous, and bedding plants. One command from my employer was that it was to be remodelled and managed—as it was termed—the same as the beds at the Crystal Palace. What was my duty under a command of that sort? Unhesitating obedience. And during the autumn months, in a dry and glorious climate, when only the family resided, no other style of flower gardening or class of plants could possibly in that hot, dry soil have yielded a tithe of the pleasure from August to November which bedding plants did. Now, this was just the proprietor doing with his own as he liked, and I would ask, Who has any right to interfere with or remonstrate with him for so doing? Certainly not the gardener, and as certainly not any outsider. And I am of opinion that any gardener who attempts to dictate to his employer will very soon come, and ought to come, to grief. Hyde Park, the Crystal Palace, and other parks and palaces should more properly be saddled with the sin of overdoing bedding-out than private establishments. Another delusion under which our reviewer seems to labour is that

gardeners object to their employers going into their gardens and picking flowers and fruits. Now speaking from experience, I never had an employer who once came into the garden and picked any flower or fruit beyond the most paltry thing without either telling me that he had done so, or leaving word to that effect with some one in charge. I consider it impossible for any of them to have supposed that I should have objected; nevertheless, I unhesitatingly affirm that no lady or gentleman properly so-called could, after due consideration, follow any other course than the one which I have named. Where there are more than two or three persons concerned, I hold that it is nothing but right that a gardener who is responsible for choice flowers and fruits should know who gathers them, but I do not believe that any gardener could object to any such wish or act of an employer; nevertheless, I would advise a different course. An employer may just as well allow some of his family to make free with his secretary's cash-box without liberty as to allow them to go and pick Peaches and Grapes, for which the gardener is held responsible, without a distinct arrangement and understanding. No doubt there are gardeners who do not know their duty or their interest, but it is unfair for any one to single out such and brand the whole class with ignorance and conceit. I will just say in conclusion that the "Saturday Reviewer" must be very unfortunate indeed if his make-believe gardener is one of the ninety-and-nine who is ignorant enough and conceited enough to think that if thwarting his employer and not doing all he can to meet his wishes, no matter what fashion those wishes take, he can hope to succeed. The sooner he discharges such a servant the better, and the fraternity he represents can very well afford to do without him.

DAVID THOMSON.

Drumlanrig.

The "Saturday Review" writer's description of the conceit and ignorance of modern gardeners can only apply to a very small section of them, and very likely the only one of which he has any knowledge. As has been observed, "nobody, knowing anything of gardeners as a class, would have written the unwarrantable statements against them made by the writer of the article in question." He makes an unfortunate mistake in regard to the modern gardener's training. It is well known that most gardeners of note have served an apprenticeship in gardens in which the whole routine of gardening is learned by them. They then try to get into one of the large London or country nurseries, as the best places in which to acquire a knowledge of plant-growing before they take situations for themselves. Among other charges, one seems to be not keeping the pleasure-grounds in beauty all the year round, and another is not having the kitchen-garden well stocked with the necessary crops. Gardeners are likewise said to enforce the law that none of the family are to cut flowers or to touch the fruit, for their greatest ambition is to see their names ticketed as prize-winners at flower-shows. A thing of beauty is said by Keats to be a joy for ever, but gardeners are stated to hate Wild Primroses, Hyacinths, Honeysuckles, and Foxgloves, and to devote all their attention to bedding plants, and in arranging them in rows or patches. Perhaps the gravest charges brought against them are transplanting trees or plants in the hottest time of the day, gathering fruit when it is raining, and taking possession of every green thing, thus adding insult to injury if interfered with by their employers. This is the crowning climax of the writer's charges, and it makes one really wish he had never belonged to the "grand old gardener's" craft, to hear of the ignorance and misdeeds with which modern gardeners are now charged in the "Saturday Review." However, if the writer of the article in question should ever own a charming garden, I hope his success in teaching the intelligent labourer how to manage it will be duly recorded, so as to afford an example to us retrograding practicals.

WILLIAM TILLERY.

Welbeck.

The correspondent of the "Saturday Review," who has taken gardens and gardeners in hand, evidently has a very limited knowledge of both. He summarily sets employers down as hopelessly imbecile, and as squandering their money in an aimless manner, whereas anyone conversant with "facts" knows that the writer has allowed his "imagination" to get the better of his judgment. He denounces gardeners as tyrannical and prosaic creatures, with no love or perception of the beautiful in Nature, and only seeking their own personal gratification. But we all know that those who are not naturally fond of their calling, and who do not make good use of their abilities, are seldom called upon to occupy places of trust; in fact, they cannot by any stretch of imagination be called "gardeners" at all. Some, as a matter of course, enter the profession who are totally unsuited for it, and who never acquire anything more than a superficial knowledge of their business, but gardening does not stand alone in this respect. The writer in the "Review"

speaks of hardy fruit culture as if it were a thing that might be learned, like some fashionable accomplishment, in "six easy lessons," whereas those who have devoted whole lives to gardening will admit that there is always much to be learned even by the most experienced. The writer in question seems to think that any owner of a garden could succeed with the assistance of an intelligent labourer, and some one to do the pruning, but has he any knowledge as to when the pruning should be done? Some call cutting off the fore-right shoots in summer and a good thinning in winter—pruning, whereas successful cultivators find it to be a much more complicated operation, and one which should be done at various seasons, in order to suit the requirements of individual trees, and the circumstances under which they are placed. Gardeners are charged with converting the whole of the gardens under their care into experimental grounds, whereas their interest is to consult and carry out as successfully as possible the wishes of their employers. That gardens have degenerated of late years is contrary to fact, for, although the system of bedding-out may be too formal, there is a decided improvement visible when the form of beds admits of any latitude in other directions. The plan of giving prizes for stilly-trained specimens at shows is the only reason why the practice is perpetuated, for gardeners, as a rule, do not train, or tie any plant that looks better without such attention. Doubtless, it is possible to have a charming garden without a greenhouse, but, in order to have flowers, fruits, and vegetables out of their natural seasons, glass is necessary.

J. GRÖÖN.

Henham.

I consider that the writer in the "Saturday Review" has done an injustice to every gardener in the country. On what grounds does he bring such charges against us, and why should he say that our gardens have degenerated, and our employers know nothing about flowers? "Gardeners," he says, "make no attempt to learn how to keep pleasure grounds in beauty all the year round, or the kitchen garden well stocked with the necessary crops." Twenty years' experience, both in England and in Ireland, enables me to give an emphatic denial to this statement. I defy him to find a gardener in the country who is not always pleased at being able to afford his employer an opportunity of making presents of fruits and flowers to his friends. Certainly we like to see our names on prize tickets at flower shows, but that is not our only ambition, nor is winning a prize, I apprehend, any sign of ignorance, especially a first prize. Neither do we waste our time on a few sticks of early Celery. The writer in question speaks of Azaleas the shape of haystacks, and covered with bloom, as being, according to gardeners, the perfection of art and beauty. Well, they are certainly effective, but, nevertheless, though not so strikingly showy, we can also admire a Cloth of Gold Rose, and we do not hate, but, on the contrary, admire and cultivate the different varieties of Primrose, and likewise respect the wild Hyacinths and the starchy Windflowers. He may have seen some gardeners, so called, transplanting and watering in the hottest part of the day, and gathering fruit when it was raining; but they must, I imagine, have been half-gardener and half-footman. I would advise our would-be critic to visit some good gardens, and learn something more about a class of men with whom he does not at present seem to be well acquainted before he next writes about them in such disparaging terms.

JOHN CLARKE.

Cork.

THE PAINT ROOT AND ITS CURIOUS EFFECTS ON PIGS.

THOSE who study the native plants of the Northern States, know as an exceedingly rare and local one, *Laohnautes tinctoria*; the first or generic name means woolly flower; and the second, or specific name tinctoria, has reference to its dyeing or colouring properties. In some works Red Root is given as the common name of this plant, but as this same name is, in various parts of the country, applied to at least three other plants, it is preferable to accept that by which this is known in the Southern States, where it is most abundant, and call it Paint Root. In favourable localities its stem grows from, 2 to 3 ft. in height, the leaves, about half as long as the stem, are narrow, the lower ones clasping one another like those of an Iris; the flowers are in a dense cluster at the top of the stem, and being woolly without, and of a dingy yellow colour within, cannot be called showy. While the minute structure of the flowers is of interest to the botanist, we ("American Agriculturist") will not describe them further than to say that they are six-parted, and have three stamens and a single style. The plant belongs to the Blood-wort family, (*Hæmodoraceæ*), of which we have but few examples in this country, and among familiar plants it is most closely related to the *Amaryllis* family, to which the Jonquils, Narcissi, and others of our spring garden flowers belong. The Paint Root contains an orange-coloured juice in its stems, and

especially in its fibrous roots, which are red, and are said to yield a dye similar to that of Madder, but we cannot find that they have ever been largely used for this purpose. This plant is very abundant in the Southern States, from Florida northward, in sandy swamps near the coast, and is common in the Pine barrens of New Jersey. Many years ago while with a party of botanists exploring a little known portion of Rhode Island, where within a restricted area the plants are more like those of North Carolina than those of New England, the late Prof. Bailey, of West Point, who was one of the party, shouted with surprise when this plant was met with; he said he should not have been more astonished had he met with a Palmetto growing wild in that locality, which is not far from Kingston, Rhode Island, and, so far as is known, its northern limit. We have described this plant fully, not because it is of botanical interest, but for the reason that, insignificant though it may appear, it has an important bearing upon the agriculture of many of the Southern States. Those who have travelled much in the Atlantic Southern States, from Virginia to Florida, are aware that black pigs are much more common than white ones; the reason given for this preference for black pigs has been that they do better under a hot climate than white ones, the same as negroes are better suited to such conditions than white people. While it appears that the skin of black pigs is less affected by the intense heat of the sun than that of white ones, this is by no means the only reason, or the main one, why dark-coloured pigs are more common throughout the Southern Atlantic States than the light ones. So far as this portion of the country is concerned, it turns out that the plant in question, the Paint Root, is at the bottom of the great preponderance of black over white pigs, as the white ones, if allowed free access to the Paint Root, are soon killed off, while the black ones can eat it with impunity and even fatten upon it. Darwin, in that remarkable book "Plants and Animals Under Domestication," quotes this case to show that characters of trifling value, such as that of colour, may be of importance in Natural Selection, in adapting animals or plants to a locality, as they are known to be in Artificial Selection by man. The immunity from adverse influences of certain dark-coloured fruits is pointed out by him, and that of black pigs in this case, is not the only instance in which there is a direct relation between the colour of animals and their adaptation to certain localities, and their susceptibility to certain poisons. White horses in Eastern Prussia, if they eat mildewed Vetches, soon have ulcers break out upon the skin, and even those which are spotted with white have every place upon which there are white hairs affected by troublesome sores, while horses with no white spots are not injured. In a part of Sicily there are only black sheep, as the white ones are all killed by a species of St. John's Wort (*Hypericum*), which grows there, and other instances are given. The case of the black pigs in this country is quoted by Darwin on the authority of that acute observer, the late Dr. Jeffries Wyman. Upon this point we are able to present very recent testimony from Dr. Stotesbury, one of the executive committee of the Georgia State Agricultural Society, a gentleman who takes a most lively interest in every product of his State. Dr. S. writes us that his own experience, and that of his neighbours, is, that while black pigs are unharmed by feeding on the Paint Root, white ones are invariably injured by it; the white pigs, if allowed to feed freely upon it, become lame, with every appearance of founder; ultimately their hoofs drop off, and deformed hoofs may grow out; in the meanwhile the pigs become permanently blind. If when blindness and lameness are first noticed in young pigs, they are removed to a pasture where they cannot get at the root, they soon recover; and even old ones that have become incurably blind will take on fat if given other food, and their flesh may be eaten without ill effects.

Tropical Varieties of Beans.—Some of the tropical species of Peas and Beans are exceedingly beautiful, being of an almost dazzlingly-brilliant colour. A few years ago I procured a number of varieties from Hindostan, China, and Japan, among which were some that were not only beautiful in their dried state, but the growing plants were so entirely different from our ordinary kinds that one could scarcely believe them to be Beans. A collection of from fifty to a hundred kinds of Beans is not difficult to obtain by a little perseverance, and if arranged in neat phials they form an ornament worthy of a conspicuous place in any house.—A. S. FULLER.

Fruits do not Wear Out.—Many distinguished men maintain that they do; but this I conceive to be incorrect. Harvey has placed this matter in its true light by showing that the real life of a tree is in its buds, which are annual, while the tree (trunk) itself is only the communicating link between them and the ground. Any portion of such a compound existence, grafted upon another stock of the same family, will produce a new tree like the first.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

MARCH 15TH.

Among plants exhibited on this occasion, that to which most interest was attached, was undoubtedly a specimen of *Xanthoceras sorbifolia*, shown by Messrs. Veitch & Sons; and the same exhibitors also showed magnificent collections of Orchids, Hyacinths, Tulips, and other decorative plants not for competition. Messrs. Cutbush & Son were to the fore with Hyacinths and Tulips, and Mr. J. Douglas took the principal prizes in the amateurs' class. Mr. S. Ford, of Leonardlee, and Mr. W. Paul, of Waltham Cross, furnished large collections of Apples in admirable condition.

First Class Certificates.—These were awarded to the following new and rare plants:—

Xanthoceras sorbifolia (Thibaut & Keteleer).—A beautiful free-blooming Japanese shrub, a coloured plant of which appeared in THE GARDEN last year (see p. 524, vol. vii.); it bears terminal clusters of white petalled flowers, blotched with reddish brown, prettily contrasted with tender young foliage in the early spring months. Planted out either in sheltered positions on the lawn or in shrubberies, it cannot fail to have an excellent effect; or it may be lifted and forced in heat as easily as a Lilac.

Hippeastrum Thalia (Veitch).—A large fully expanded flower, fully 9 in. across, and of a dense crimson colour. Its flowers are borne on short stout scapes.

H. Clio (Veitch).—A robust variety similar to the last, but with smaller flowers of a vivid scarlet colour.

Abutilon Darwinii tessellatum (Veitch).—An attractive form of the new A. Darwinii, to which a certificate was awarded last year, and like it bearing orange scarlet or vermilion bell-shaped flowers. Its leaves, which have a soft hairy texture, are cordate at the base and trilobed at the apex, dark green in colour and profusely blotched with golden yellow.

Phalœnopsis Veitchii (Veitch).—This is a very distinct and beautiful plant, supposed to be a natural hybrid between *P. rosea* and *P. Schilleriana*. In shape its flowers are like those of *P. rosea*, but much larger, being nearly 2 in. across, and of a delicate rosy lilac, the three-lobed lip being of a much deeper colour, with a golden crest dotted with crimson.

Odontoglossum Chestertonii (Veitch).—A New Grenadian plant in the way of O. Andersonianum, but with rounder flowers; its sepals and petals are creamy yellow in colour, heavily blotched with chocolate, and the lip is pale yellow and also blotched with the same colour. It is a distinct variety, and well worth attention.

Hyacinth Sultan (Veitch).—A robust variety, furnished with a dense spike of rich dark violet-purple flowers, of good form and substance.

Hyacinth The Shah (Veitch).—A light bronze-like purple kind, producing a dense spike of flowers, well up above the leaves.

Hyacinth The Golden Lion (Veitch).—A clear canary-yellow variety, having a dense spike of well-formed flowers.

Cyclamen Purple Gem (Goddard).—A distinct variety, compact in habit, and having flowers of a deep crimson-purple colour. It is a kind which promises to produce a very distinct and attractive strain of dark-flowered varieties.

Hyacinths.—In the class of fifty Hyacinths, single spikes, Messrs. Cutbush & Son, of Highgate, were first with a very fine group, in which were the following, viz.—*Light Blue*: Lord Palmerston, Blondin, Charles Dickens, Grand Lilas, Czar Peter, Lord Byron, and Pieneam. *Dark Blue*: Leonidas, Marie, Baron Van Tuyll, King of Blues. *White*: Baroness Von Tuyll, Snowball, Emmeline, Miss Nightingale, Alba maxima, and La Grandesse. *Rose*: Von Schiller, Princesse Charlotte, Duchess of Richmond, Vaurbaak, Prince of Orange, Lina, Macaulay, Koh-i-noor, and Duc de Malakoff. *Purple*: Incomparable, Ferock Khan, General Havelock, Lord Melville, Frinco Albert, and others. Messrs. Barr and Sugden were second with well-grown plants; but not quite so equal as those just named. Among these we remarked *Solfaterre*, a bright rosy scarlet, with a white eye; *Voltaire*, a large, pure white kind; *Pelissier*, rosy crimson; *Gigantea*, a narrow-petalled, pale rose; and *Ida*, clear canary-yellow. In the class of eighteen spikes Messrs. Cutbush were again first with very fine examples, among which we noticed *Grand Lilas*, *Light Blue*; *La Grandesse*, white; *Bird of Paradise*, yellow; *Lord Derby*, pale blue, and *General Havelock* and *Lord Melville*, both good dark purplish blues. Messrs. Osborne, of Fulham, were second in this class; and Messrs. Carter & Co., of High Holborn, third; the varieties in both cases being the same as those already enumerated. In the amateurs' class of twelve varieties Mr. J. Douglas, of Loxford Hall, Ilford, was first with plants in every way excellent. In this group the best spikes were those produced by *King of the Blues*, dark blue; *Mont Blanc*, white; *Ferock Khan*, single, dark blue; *Koh-i-noor*, rose; *Van Speyk*, double, blue; and *Fabiola*, rose-striped. Mr. J. Weir, gardener to Mrs. Hodgson, The Elms, Hampstead, was second with good examples of *Czar Peter*, light blue; *La Grandesse*, Garibaldi, Charles Dickens, Marie, Grand Lilas, and General Havelock.

Mr. J. Moorman, gardener, Coombe Bank, Kingston-on-Thames, was third.

Tulips.—In the class of twelve single Tulips Messrs. Cutbush were first with *Vermilion Brilliant*, scarlet; *Joost Van Vondel*, crimson flecked with white; *Canary Bird*, yellow; *Van der Neer*, purple and yellow; and *Pottebakker*, clear yellow. Messrs. Barr & Sugden were second with *Proserpine*, rosy purple; *Joost Van Vondel*, *Vermilion Brilliant*, *Van der Neer*, *Duchesse de Parma*, scarlet and yellow. In the amateurs' class of twelve Mr. J. Douglas was first with *Chrysolara*, clear yellow; *Vermilion Brilliant*, scarlet; *Proserpine*, *Wouvermans*, purple; *White Pottebakker*; and others. Mr. J. Weir was second with nearly similar varieties: *Roi Pepin*, white flaked with crimson, being the only exception. Messrs. Barr & Sugden staged a well-grown collection of Tulips in the miscellaneous class; and of *Crocuses* a mixed collection, consisting of variously coloured kinds, came from Messrs J. Veitch & Sons.

Miscellaneous Spring Flowers.—Of these Messrs. Veitch staged an interesting group, consisting chiefly of *Hyacinths*, among which were remarked *Argus*, blue with white eye; *Princess Mary of Cambridge*, pale blue; *Garibaldi*, crimson; *Haydn*, purple; *Von Schiller*, bright rose; *Blondin*, and *Lothair*, pale blue; *Prince Albert*, black-purple; *Miss Nightingale*, salmon-rose, and others equally good. Among white kinds, which are so useful at this season for bouquets, &c., we noted *L'Innocence*, *La Grandesse*, *Mont Blanc*, *Alba Maxima*, *Baroness Van Tuyl*, *Snowball*, and *Lord Shaftesbury*; the last producing pips or bells measuring nearly 2 in. across, and of a massive wax-like substance, somewhat like a variety exhibited a year or two ago under the name of *Anna*. *Crimson*, yellow, scarlet, and variegated Tulips were well represented; the varieties being *White Pottebakker*; *Proserpine*, red; *Queen of Violets*, violet-purple; *Fabiola*, purple flaked with white; *double yellow Tournesol*; *double Salvator Rosa*, soft rose; *double Titian*, scarlet edged with gold; and many others. Miscellaneous collections of *Hyacinths* also came from Messrs. Osborn & Sons, and from Messrs. Carter & Co., High Holborn.

Orchids.—Of these Messrs. Veitch exhibited large and attractive groups, both in the Committee-room and in the Arades. Among them we remarked a fine plant of the delicate white-flowered *Dendrobium glaucum*, bearing some seventy spikes; *Dendrobium Jamesianum*, remarkably well flowered, as were also *D. aggregatum majus* and the white form of *D. Farmeri*. A plant of the curious *Vanda cristata*, a native of the Sikkim Himalayas, bore two spikes of greenish flowers, the fleshy trilobed lip being streaked and blotched with very dark purple. Other plants consisted of well-bloomed specimens of the thick bulbed form of *Trichopilia suavis*; *Phalaenopsis Schillerianum*, *Dendrobium Wardiana*, *Lycastes*, *Odontoglossa*, and *Masdevallia*. A beautifully-flowered plant of *Dendrobium Heyneanum* came from Sir Trevor Lawrence's garden at Burford Lodge, Dorset; it has brown, leafless pseudo-bulbs, remarkably well flowered, and the specimen staged bore on one bulb four dense spikes of pure white flowers; the same exhibitor also showed an unnamed species of *Spathoglottis* bearing a slender raceme spike of drooping yellow flowers 1½ in. across. Mr. Denning, gardener to Lord Londesborough, Surbiton, sent a perfect specimen of the old *Ornithidium cocconium*, a plant which bears a profusion of brilliant coral-tinted flowers and buds among foliage of the freshest green imaginable. This *Orchid*, which is now scarce, is when well-grown one of the most distinct and beautiful of the class to which it belongs. Mr. Ollerhead, gardener to Sir Henry Peck, Bart., Wimbledon House, furnished a superb variety of *Phalaenopsis Schilleriana*, bearing well-rounded blooms fully 2 in. across, and of great substance, the colour being white, delicately suffused with rosy lilac; also a plant of the purple-flowered *Dendrobium litiflorum*, bearing forty-three flowers on two bulbs, each a yard in length. A plant of the thick-bulbed variety of *D. Wardianum* bore eighteen large flowers of wax-like substance, the petals being delicately tipped with magenta purple. Mr. Michaels, of Cholmeley Park, Highgate, sent a very fine light-coloured variety of *Oncidium Weltonii*, but unfortunately it did not arrive until after the business of the Floral Committee was concluded.

Roses.—A very fine collection of forced *Roses* came from Messrs. Veitch & Sons, both flowers and foliage being remarkably fresh and beautiful, each specimen bearing from six to twelve blooms. Among these the best varieties were *Senator Vaisse*, crimson; *La France*, peach; *M. Verdier*, delicate rose; *Jules Margottin*, *Cheshunt Hybrid*, rosy crimson; *Paul Neron*, a large open rosy flower; and *Madame Falcot*, with delicately-shaped salmon-tinted buds, and pale yellow flowers. Messrs. W. Paul & Son furnished a beautiful stand of cut blooms, among which were the *Yellow Banksian*, *alba rosea*, *Maréchal Niel*, and other select kinds.

Hardy Flowers.—Of these Mr. Parker, of Tooting, showed an interesting group in pots. Prominent among them were *Primula acutis coraculæ*, a light blue-tinted variety with a yellow eye; two or three white and blue-flowered *Hepaticas*; *Helleborus colchicus*, a purple flowered form, and *H. guttatus*, a large white variety splashed with red; *Scilla bifolia rubra*, a delicate rosy variety; *Iberis semperflorans*, pure white; and a pan of the rich purple *Iris sibirica*, bearing forty or fifty flowers; a group of *Apogoneton distachyon* in this group was also much admired. Mr. R. Dean, of Ealing, furnished two collections of hardy *Primroses*, to which first and second prizes were awarded. Among them were some fine seedling forms, of good colour and free-flowering habit. Messrs. Carter & Co. showed a new seedling *Primrose* in the way of *P. altaica*, having bluish-purple flowers; this was named *Lady Adelaide Taylor*. Mr. R. Dean contributed six new seedling hardy *Primroses*,

the colours of which were purple, lilac, maroon, and creamy-white. Mr. G. F. Wilson furnished a flowering specimen of the delicate light blue-flowered *Scilla præcox*; also a flowering plant of *Primula viscosa*, and a plant of *Claytonia caroliniana*, the latter bearing a profusion of rosy Oxalis-like flowers; this plant had been sent to Mr. Wilson by post from the Rocky Mountains, wrapped in oiled silk. A Botanical certificate was awarded it.

Miscellaneous Subjects.—In the class of thirty *Cyclamens*, Mr. G. Goddard, gardener to J. Little, Esq., Cambridge Park, was first with well-grown specimens in 32-sized pots, each bearing on an average from fifty to sixty flowers, the colours being pure white, purple, crimson, and lilac. Mr. H. B. Smith, of the Baling Dean Nursery, was second with equally fresh but much smaller plants. In the nurserymen's class of twelve specimens Mr. H. B. Smith was first with well-grown profusely-bloomed plants, while in the amateurs' class Mr. G. Goddard was first with a similar number, the specimens in this case being in large pots, and remarkably fine. Mr. James, gardener to W. F. Watson, Esq., Redlee, Isleworth, was second with smaller plants. For *Chinese Primula* Mr. R. Dean was first in the nurserymen's class with twelve well-grown plants, the colour of which were white, lilac, rose, purple, and blush. Mr. J. James was first in the amateurs' class with large and well-bloomed specimens; and Messrs. J. Dobson & Son, of Isleworth, contributed two large stands of their strain of decorative varieties. In the class of six *Cinerarias*, Mr. James was first with dwarf well-flowered plants, the flowers of which were of good form, and the colours bright and distinct. Mr. B. S. Williams showed a fine bank of *Orchids*, *Ferns*, *Amaryllids*, *Palms*, and other decorative plants, all in excellent condition; and from Messrs. Osborn came a miscellaneous group of rare and new *Palms*, *Abutilons*, *Dracænas*, and other decorative stove plants. Messrs. Rollisson showed a collection of plants, consisting of the deliciously-perfumed *Boronia megastigma*, their new *Grevillea Friesii*, and a showy group of forced varieties of the orange and rosy-flowered *Azalea mollis*. Mr. Aldous furnished *Cinerarias*, *Rhododendrons*, *Camellias*, and other decorative plants. Mr. W. Paul sent six stands of cut *Camellias*, all in fine condition. A large-flowered greenhouse *Rhododendron* named *R. Fisher Holmes* came from Messrs. Fisher Holmes & Co., of Sheffield. It has large, white, delicately-perfumed flowers, each measuring 3 or 4 in. across, and small, glossy, green leaves. It is said to be a cross between *R. Edgeworthii* and *R. Gibsoni compactum*, and is evidently a most profuse bloomer, although the specimen staged had suffered somewhat in transit. Mr. E. Bennet, Rabley, exhibited a very ornamental, semi-double variety of *Cyclamen persicum*, bearing large, rosy, crimson flowers, well elevated above the leaves; this will be a desirable variety if it can be propagated or perpetuated from seeds. Mr. Goddard, of Cambridge Park, Twickenham, showed seedling *Cyclamens*, good in habit and distinct in colour; among these one of the best was *Purple Gem*, alluded to elsewhere.

Fruit.—Mr. J. Douglas, of Loxford, sent a plant of *St. Michael's Orange*, bearing some twenty fine fruits. Several dishes of seedling Apples were staged, but none worthy of a certificate. Messrs. Hooper, Covent Garden, sent a dish of *Alpha Potatoes*, planted on the 13th of January last, and dug on the 7th of March. Two large and well-kept collections of Apples were staged in admirable condition—one by Mr. Sidney Ford, of Leonardisle, Horsham, and the other by Mr. W. Paul, of Waltham Cross. To each of these a silver medal was awarded. Among the different varieties we noted *Winter Codlin*, a large culinary fruit; *Poor Man's Profit*, *Yorkshire Greening*, *Hoary Morning*, *Minchall Crab*, *Norfolk Beefing*, *Royal Russet*, *Blenheim Orange*, *New Hawthornden*, *Winter Nonsuch*, *Holland Pippin*, *St. Leonard's Nonpareil*, *Adam's Pearmain*, *Ribston*, *Winter Pearmain*, *Golden Reinette*, *Pearson's Plate*, *Dredge's Russet*, *Alfriston*, *Mother Apple*, *Calville Malingre*, *Belle du Bois*, *Boston Russet*, *French Crab*, *Norfolk Colman*, and *Wadhurst Pippin*.

NOTES AND QUESTIONS—VARIOUS.

Catfall's Silver Ball Turnip.—I believe this to be the best white Turnip for sowing now. It is a veritable silver ball in appearance, so smooth and clear is the skin, and the flavour is excellent.—E. HOBBS, *Ramsay Abbey*.

Potatoes Quickly Raised from Seed.—Last spring I obtained from Mr. Pringle, of Vermont, some of his hybridised Potato seed, which I planted in a hot-bed in the middle of April, and transplanted the produce to the open ground on the 10th of May. One plant yielded 10½ lbs. and another 6 lbs. of large, smooth, handsome Potatoes.—J. H. FRANKS.

Celastrus scandens.—"R." (p. 256) would find this shrub in most of the nurseries where hardy shrubs are to be obtained; but I think he would scarcely associate it with them now. I had it for several years, and then discarded it, as it never flourished, and was of no special beauty, either in foliage or habit of growth.—H. N. ELLICOMBE, *Elton Vicarage*.

The Chufa.—This is the tuber of *Cyperus esculentus*. From your account of it (see p. 243), the plant and the tuber have both grown considerably since London's time, for he gives the height of the plant as 1 ft., and the "tubercles round, about the size of Peas." Is this the result of cultivation? or have you given your readers an "American" history of the *Ananás de Terre*, as the French call it?—W. T. T.

Plane trees in Germany.—Dr. Bolle, in a communication to the Botanical Society of Berlin on the species and varieties of the *Plane tree* in cultivation, states that the American *Platanus occidentalis* appears to be perfectly hardy in Germany. He also mentions that seed from the variety *foliata* of P. orientalis, in some instances showing the form of the typical form. According to the same authority *Boureaux* found considerable forests of *P. acerifolia* in Lycia, and dried specimens exist from Syria.—V.

No. 227.]

SATURDAY, MARCH 25, 1876.

[Vol. IX.]

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

WELL-GROWN CAMLLIAS.

WELL-GROWN Camellias are comparatively rare in this country, a circumstance the more remarkable inasmuch as, from the length of time the plant has been under cultivation, and its recognized decorative value, one would have thought that even the most minute detail respecting its management would have been familiar to every plant grower. This, however, does not appear to be the case. Collections here and there planted out are satisfactory; but specially good culture in pots or tubs is rarely met with. The best collection of Camellias that I ever saw in pots was at M. Chantin's place, near Paris; there several large houses were completely filled with specimens varying from 2 ft. to 6 ft. in height, and proportionately large in breadth. They were mostly pyramidal in shape, and well furnished to the rim of the pots with foliage of the very healthiest description. Camellias in this establishment were a speciality, and no pains or expense were spared to render the collection complete, both as respects variety and perfection of culture. One of the best single specimens with which I ever met was at the Paris Exhibition of 1867. It came from near Lago Maggiore, and was really a model of what a Camellia should be. It was a perfect pyramid, and, as near as I can recollect, was about 8 ft. in height, and about 5 ft. through. Larger plants I have seen, but never one so perfectly formed, and in such a high state of health. The Camellia, although one of the easiest plants to grow, dislikes forcing of any kind; and to this peculiarity I attribute in a great measure the want of success as regards the production of specimens. By forcing I mean an attempt to induce rapid growth by means of large shifts, rich composts, and stimulating manure-water. It is remarkable in what a small quantity of soil a Camellia will live, and even thrive, and the constant aim should be to secure a good head of foliage in a small pot. If this be secured at an early stage of growth, the afterwork will be comparatively easy. Overpotting, and the use of raw, heavy loam, produce a sickly yellow growth; buds may be formed on such plants—and they often are in abundance—but the plant has not vitality enough to withstand any sudden change of temperature or slight check to which it may be subjected, and the result is they all, or nearly all, drop. This often happens when the plants, after having been out-of-doors, are introduced to their winter quarters, and people are surprised at the circumstance; but, if one of the plants were turned out of their pots, and an examination of the roots made, wonderment would cease. The little fibre that can be made during the summer-time in a close, ungenial soil becomes completely ruined by the autumn rains. Those, therefore, who would wish to grow Camellias well should begin with quite small healthy plants; they will then be able to lay the foundation of good specimens. Unless this be secured, no real substantial success can be relied on, for no amount of after-care will wholly compensate for injudicious treatment or neglect during the early stages of growth. Old, neglected Camellias may be renovated; but such work needs time and patience, and requires considerable judgment and experience to achieve. A good free, healthy root-action is the main point to be secured, and, in order to obtain this, we must not be in too much haste, for, as I have already said, the Camellia will not submit to being hurried. No plant is more willing to yield good results under pains-taking culture, but it imperatively demands that its peculiarities be studied. Healthy young plants in 48-sized pots, quite large enough to begin with, may be procured, fairly rooted; they should be dwarf, furnished with several shoots, and well clothed with foliage. They should be wintered in a light house, in which good ventilation can be given; and all buds should be picked off, growth not flower being now the chief object to be aimed at. If the plants have been more than one season in the same pots, the soil will pro-

bably be well filled with fibres, and they may be advantageously shifted into a larger-sized pot; if, on the contrary, there be any paucity of roots, or they appear to be in rather an unhealthy condition, the better way will be to go over them with a sharp-pointed stick, extract as much of the old soil as possible, and fill up with a compost consisting of peat, leaf-mould, and sand, in equal proportions. This will induce the old roots to produce fresh fibre, and encourage the young rootlets to a more lively and healthy action. In this way an extra amount of vigour will be gained without the bulk of the soil being augmented; the drainage, too, should be looked to, and the plant replaced in a clean pot. If this be done as soon as the wood is ripened early in autumn, and while the roots are in active growth, much will be gained, as in the spring when making their young wood, they will be in a condition, be benefited by an occasional watering with clear soot and guano-water. Although, however, manure-water may be sometimes applied with advantage during the growing season, it must be used with judgment. A newly-shifted plant will not require any stimulus, but if the head of foliage be large and the pot well filled with roots, a pinch of guano in the water, given now and then, will be found to produce good results. No rule can, however, be laid down in this respect, practice and observation will alone enable the cultivator to treat each plant according to its individual requirements. In the employment of soot-water no mistake can be made, inasmuch as soot is the manure *par excellence* for the Camellia; there is no danger of souring the soil with it, and it may be given with benefit at all times of the year; its employment either in the form of manure to the roots or in that of outward applications to the foliage, in the way of syringing, is equally beneficial. The best and easiest method of using it is to tie some up in a bag and place it in the water-tank, in which the properties of the soot will be extracted without leaving any scum on the water. This water may then be used for syringing, and will leave no stain on the foliage. Soot-water, without stimulating rank growth, promotes the formation of firm, sturdy wood, gives plumpness to the buds and colour to the foliage, such as no other manure will produce; but these results will only be effected by its constant use and if prepared in the manner just stated. The Camellia is naturally impatient of a strong glare of light or hot sunshine; it loves and luxuriates in partial shade—filtered sunlight, so to speak, such as a shrub gets which stands upon the clearing of a wood, partly overshadowed and protected by larger neighbours. Shade in the growing season will, therefore, be necessary, combined with abundance of atmospheric moisture; a good washing with the syringe, morning and evening, and damping down the walks and stages on hot days, will supply the latter desideratum. In dull damp sunless weather, however, the syringe should not be employed, or weak, flaccid growth will be the result, which, later in the season, will affect the general appearance of the plant, and certainly impair its bushy shrub-like habit, which is the true characteristic of a well-grown Camellia. Drawn, spindly growth when the plant is young results in naked, leafless branches when old, and, in order to regain symmetry, the knife has to be used; but this will never be found necessary if sufficient air be given during the growing season. When the young wood is made and fairly ripened, the plants should be turned out into a cool sheltered spot. If they have been properly cared for during the summer, and are in all respects in a good healthy condition, they may safely be allowed to remain undisturbed for a while, and an occasional heavy shower of rain will do them no harm; in fact, a few good early autumn showers seem to fill up the foliage in a manner unattainable by the watering-pot and syringe. If any of the plants, however, should appear to be at all imperfectly rooted, they should be placed where they can be sheltered at will from heavy rains. A deep pit is the best place in which to put them; but, if that accommodation cannot be had, they should be housed early before heavy rains are to be apprehended. The time required for the formation of good large plants may be much shortened if the bloom-buds be all picked off, inasmuch as each flower allowed to expand lessens the vigour of the season's growth. I know an estate on which the owner goes annually over the *Rhododendron*

plantations and removes every bud; his object in so doing being to secure luxuriant and healthy foliage. There are not many, perhaps, who would be willing to make this sacrifice for the sake of extra verdure; but tastes differ, and flower is but transient, while foliage, such as that of the Rhododendron, is pleasing at all times of the year. Be that as it may, the effect of the removal of the bloom-buds in this instance has had a marked effect upon the development of the plants, which are models of healthy vigour. The kind of soil best suited for the Camellia has been frequently discussed, the majority of English growers pertinaciously clinging to strong loam. There must be no admixture of any kind. Others, on the contrary, advocate a mixture of fibry peat and loam, and some even recommend other ingredients; while a few, but very few indeed, are willing to admit that the loam may be nearly or quite dispensed with. Loam, no doubt, as procured in some localities, is excellent; but there are only a few samples which may be safely used in a pure state for plants which, like the Camellia, require much care as regards root-action. The indiscriminate use of loam produces, I believe, many disappointments and failures. A stiff soil requires much care in watering, and I have seen Camellias potted in a loam, so-called, which was but a few shades removed from clay. In the case of a plant standing in the open ground there is a free and natural drainage which prevents stagnation, and this may be imitated with fair success when planting-out Camellias in houses, in which, consequently, a closer and more tenacious compost may be used. In placing a plant in a pot we give it a purely artificial state of existence, and must, therefore, endeavour to neutralise, as much as possible, the ill effects attending the circumstances under which it is placed. The best soil in which to pot a plant is in that which yields the most nutrition, and, at the same time, favours the highest amount of root development with the greatest facility for preserving the same in a healthy condition. In stiff, tenacious, moisture-holding composts, these requirements do not exist, and they should, therefore, be avoided, more especially by amateurs or others who may be desirous of growing a class of plants with whose peculiarities they may be but imperfectly acquainted. Experienced cultivators alone should indulge in the use of unctuous soils and strong composts. In the case of the Camellia I should recommend a soil of a mixed and varied character and rather light than heavy. I have grown Camellias in a mixture of leaf-mould and fibry peat, intermixed with bog-earth and charcoal. This compost does not encourage rank growth, but in it the leaves acquire good substance, and a fine gloss which can hardly be obtained in a soil of which loam forms the principal ingredient. If I had a choice of soils in a thoroughly pulverised condition, I would select a compost consisting of equal parts of loam, peat, and leaf-mould, to which sufficient silver sand was added to make the whole open and porous. This mixture will promote the development of wood and foliage, and if a proper drainage be provided, and the plants are firmly potted, the watering-pot may be used with freedom. When once the Camellia has acquired a certain size and is withal vigorous and in good condition there will be no necessity for diminishing the floral display; self-denial will then reap its reward, and a glorious profusion of bloom may each season be looked for and indulged in without detriment to the health of the plants. Should, however, any one specimen show signs of ill-health, give it a rest by divesting it of bud, and that, with care in other respects, will generally be found sufficient to restore its lost vigour. Those in possession of old neglected plants may try their hands at renovating them if they should feel disposed to do so. As the source of evil will generally be found at the root, they should be shaken out of their pots, as much of the old soil as possible should be removed, and the roots washed clean. Old roots decayed at the end should be pruned back with a sharp knife; the whole should then be dressed with sand, and put back into as small a pot as the roots can be got into, using a very sandy, light soil, and ensuring perfect drainage. They should then be placed in a slight bottom-heat where plenty of air can be given, syringed on warm days, and shaded from the hot sun. The first season they will probably not make a great amount of growth, but the foundation of it will be laid, and, if the pots have become filled with young healthy fibres, they will stand the next year

any little pruning that may be considered necessary to bring them into shape, and will break away freely from the old wood. Large, naked-stemmed plants treated in this way and side-grafted upon the old wood, often make handsome specimens, inasmuch as a great many grafts may be inserted on one plant. I am acquainted with a collection of Camellias which were restored from a miserable state of decrepitude to fine health by treating them much in the manner just described. They were, however, plunged in bottom-heat in the open air, having merely sufficient protection to ensure them against bright sunshine and heavy rains. The result was that the roots were excited early into growth, whilst the tops took their own time to start; and when they did so there were plenty of new roots to support it. In the course of years the plants thus renovated became noted for their beauty; they were afterwards planted out, and were literally smothered with bloom every year, whilst as regards foliage and general growth, they were all that could be desired. With respect to the best shape for Camellias, individual tastes and fancies must, of course, be consulted. They may be grown, as is often seen, in the form of standards, or in that of bushes or pyramids; the latter I consider the most desirable for pot culture. Pyramidal Camellias are, however, not often met with, mainly perhaps because attention to training them in that way is necessary during the earlier stages of growth. If, however, the foundation of a pyramid be properly laid, there is no more difficulty in preserving that form than any other, and with a little care in training, pruning will hardly ever be found necessary. A good-shaped pyramid, densely furnished with foliage and covered with bloom, is an object worth taking some pains to secure, and one which well repays any extra care and labour that may have been bestowed upon it.

Byfleet.

JOHN CORNHILL.

The Coca Leaf.—Sir Robert Christison stated, in his introductory address, delivered to the members of the Edinburgh Botanical Society, that, with a view of testing the alleged stimulant properties of the Coca leaf, he chewed some of it during two ascents of Ben Voireich. On reaching the top he felt greatly fatigued—Sir Robert is a man advanced in years—but the Coca leaf quickly relieved him, and he made the descent easily and enjoyably. He further stated that its use has enabled him to walk thirteen miles without experiencing any of the fatigue which he would otherwise have felt. Its botanical name is *Erythroxylon Coca*, the leaves of which are used as stimulants by the Peruvian Indians.

Pavia macrostachya.—The Pavia, species of Horse Chestnut, differ from it in bearing smoother fruit and in being of a more dwarf character. *Pavia macrostachya* is altogether distinct, and possesses features belonging to no other tree or shrub that we have ever seen or read about. Broader than high, stooling from the root, and covering the ground closely, it forms a hemisphere of foliage which, when adorned with its many spikes of fragrant Hyacinth flowers, blooming in July, and enduring a long time when most other shrubs have ceased to bloom, few plants will give so much pleasure. We saw last summer, in the grounds of R. B. Parsons & Co., a specimen growing under the shade, 50 ft. in circumference, 8 ft. high. Mr. H. W. Sargent mentions one in his own grounds (1867) twelve years old, 60 ft. in circumference, 8 ft. high, bearing (as he wrote) between 300 and 400 racemes of flowers. It should be planted in extremely rich soil, and—possessing in itself every charm of clustered shrubs—is, of all plants, the best suited to stand wholly isolated.—E. S. CARMAN in "Moore's Rural."—"This is indeed a shrub of remarkable value for all who pursue what the "Saturday Review" has begun to patronise as artistic gardening. It is undoubtedly, as Mr. Carman says, one of the best possible shrubs to stand alone, but we have also seen it, affording a very charming effect as an undergrowth beneath low trees. Its fine foliage and long spikes of flowers almost make one dialike calling it a shrub, as it possesses all the amplitude of noble leafage and charm of stately blossom that belong to the finest of its race. It seems indeed a tree come down to nestle on the Grass."

The Massachusetts Horticultural Society has issued its schedule of prizes for the year 1876. Among them are 60 dollars each for the best seedling Pear, Apple, and hardy Grape, with smaller ones for the small fruits, and nearly equal premiums for new flowers and vegetables, to be awarded mostly after a trial of three years. The Whitcomb premium of 200 dollars is offered for the best seedling Potato originated since 1870, and to be awarded in 1878.

THE INDOOR GARDEN.

NEW DOUBLE WHITE EPACRIS.

(EPACRIS ONOSMEFLORA FLORE-PLENO.)

THIS is the first double-flowered Epacris which has been introduced to our gardens. It forms a vigorous little bush, a good example of which was exhibited by Mr. W. Bull at the meeting of the Royal Horticultural Society, which took place on March 1st, when it received a first-class certificate, a distinction which it well deserved, for we believe that it will be

New Double White Epacris.

largely grown as a decorative plant when plentiful enough for distribution. It has deep green ovate-acuminate leaves, and axillary flowers of the purest white, each about $\frac{1}{2}$ in. in diameter, and as double as the blooms of a white Camellia. Some doubts were expressed at the meeting in question as to the identity of this plant with *E. onosmeiflora*, a point respecting which Mr. Bull gives the following particulars:—"Before my plant was exhibited there had not, I believe, been a living plant of the double-flowered Epacris seen in this country. I have been years trying to import it, but until last year always failed to get it alive. The double Epacris alluded to in 'Seaman's Journal of Botany' is in the Kew Herbarium, a dried specimen, but no living plant of it has been seen in this

country. Obviously a dried specimen in a herbarium is a very different thing from introduced living plants. However, of my plant there is not even a dried specimen in the Kew Herbarium. There is no doubt about my Epacris being a double form of *E. onosmeiflora*, which is so totally different from *E. impressa* that there can be no mistake about it. *E. purpurascens* has been adopted by some botanists as the name of the single form of my Epacris, but that horticulturally should read '*onosmeiflora purpurascens*,' for it is merely a rosy-purple variety of the species, of which the normal type is white-flowered. When I received my Epacris, the collector wrote me in ecstasies about it, and said he had seen a plant of it only 10 in. in height, of which 7 in. were so covered with double blossoms as to hide the stem, reminding him somewhat of a well-grown Balsam." Since the plant above alluded to was exhibited by Mr. Bull, we have again seen it, and also dried specimens as sent by his collector, which were even more copiously flowered than in the case of the living plant, and from these materials the accompanying illustration has been made. Well-grown specimens of it may be expected to be very effective when thickly studded with snowy flowers, and their value is enhanced by the fact that double flowers remain in perfection longer than those on the single-flowered types from which they have originated. B.

ATACCIA CRISTATA.

THE first impression produced by an inspection of this most singular plant is one of wonder as to the uses of the various strange appendages that are attached to the flowers. One might be pardoned for coming to the conclusion that it was the result of an effort on the part of Nature to produce something in the vegetable world totally different from everything else. In form, and also in texture, we find nothing like it; there are a few others nearly allied to this *Ataccia*, but it may be taken as the best representative of its particular class. The roots are thick and coarse, proceeding from a stout short rhizome, from which issue the leaves, some five or six in number. The petioles are smooth, a few inches long; the blade of the leaf is oblong acuminate, of a dark green colour, nerves prominent; in a strong plant the leaves attain a height of 18 in. As many of your readers may not have seen the flower, a description of it may be useful. The scape rises well above the leaves; it is erect, smooth, and terminated by a large four-leaved membranaceous involucre; the two outer leaflets are opposite, the two inner are placed side by side, erect, very large, almost transparent, and, like the rest of the flower, of a deep chocolate colour. The numerous peduncles are each terminated by a single flower, forming a drooping umbel. Besides these floral peduncles there are a number of others, sterile, long, drooping, and tendril-like in shape; these still further increase the singularity of the flower, than which nothing in the whole vegetable kingdom is more calculated to interest even the most casual observer. The plant is easily grown, provided a few things essential for its existence are attended to. It is found growing indigenous in Malacca, occupying damp situations; this points to the necessity for its always being kept in a comparatively high temperature, as also to the soil never being allowed to get dry. The fact of this and many other plants luxuriating naturally in swampy ground often leads to their being subjected, under cultivation, to a course of treatment that is fatal to their well-being. It is frequently supposed that, because a plant grows in a state of Nature in soil saturated with stagnant moisture, an imitation of this is essential under pot culture; whereas with these moisture-loving subjects it is just as necessary that their pots should be well drained, and the soil in which the roots are placed of such a character as will allow the water to pass freely through it, as it is with plants that exist naturally in drier ground. Anything approaching a sour condition of the soil, or deficiency in the drainage, will quickly cause the roots of the *Ataccia* to rot; after which it is very difficult to save the plants from dying, as when reduced to this state they are slow in forming fresh roots, and the soft nature of the leaves and stem is such as to cause them to flag and shrivel up when the supply of moisture requisite for their growth is cut off. The plant is propagated by division of the side-shoots which

are thrown out from the main stem. As these are produced but sparingly, it is slow to increase. The side-shoots are generally emitted near the surface of the soil, and in a few months after their appearance push out roots from the base, independent of those that support the plant. When these have attained an inch or two in length, and are about to enter the soil (in which state they will generally be found towards midsummer) the side-growths may be taken off with these roots attached, and placed singly in 4 or 5 in. pots, according to the strength of the crowns. The pots should have an inch of crocks in the bottom. The soil ought to consist of the best fibrous peat, with a good portion of the earthy matter shaken out—four parts to one of fine broken crocks and sand in equal proportions. Secure them in the pots with two or three small sticks, and give enough water to settle the soil. They should then be placed under a propagating glass, but not kept so close as many plants would require to be, or they will be liable to rot. They should stand on a moist bottom, in a temperature of 75° in the night, and 10° higher in the day with sun-heat. They must be shaded from the sun. In the course of a month or six weeks they will be well rooted, and should be placed on a side shelf near the glass. They like plenty of light, but will not bear exposure to the sun in bright weather well. When they have got inured to the full air of the stove, if in the smallest pots recommended, they should be moved into others an inch larger, using similar soil to that in which they were first placed; admit a moderate amount of air every day through the summer, give plenty of water to the roots, and moisten the plants overhead with the syringe in the afternoons when the house is closed. About the middle of September the temperature should be lowered 5° in the night and 7° or 8° in the day, giving more air and discontinuing both shade and syringing; as the days get shorter, reduce the heat 5° more, and keep them through the winter in about this temperature. During this season they make little growth, and consequently much less water should be given; but on no account must the soil be allowed to get so dry as required by many plants at this season. When the days lengthen at the beginning of March, raise the heat 5° in the night, and 6° or 8° with sun-heat, giving a little air in the middle of the day; they should then be shifted into pots 2 in. larger, using soil in every way as before. When the weather gets warmer, shade will be necessary in the middle of the day, raising the temperature day and night to the maximum point to which they were subject the preceding summer. The strongest will most likely push up one or more flower-scapes through the course of the season, but these will be much smaller than what will be produced as the plants get stronger. Treat them in every respect as during the previous summer and autumn, reducing the temperature as the days shorten, and wintering as before. The ensuing spring, about the same time, give them pots 1 or 2 in. larger, according to the progress they have made; but they must not at any time be over-potted, as too much root-room seriously affects their growth. A 10 in. pot is large enough for a full-sized plant that has got several crowns. The strongest plants will in all probability form a second crown during the season, and go on increasing each summer; if it be thought desirable to increase the number of plants rather than grow them into larger specimens, they may be divided and treated as recommended in the first instance. But it is when they have got from three to five crowns each, that they become the most effective, as in this size they will often push up four or five flower-stems at a time; and when the plants are strong they will bloom oftener. There is no stated time for their flowering, as when vigorous they usually produce a spike of flowers from each leaf, coming in at intervals through the growing season, but they mostly appear in the spring, when active growth has fairly commenced. It is not well to syringe them overhead at the time the young scape is issuing from where it is produced—the inside of the base of each leaf-stalk—as it sometimes has the effect of causing it to damp off. As the plants go on, the lower leaves will decay and fall off, leaving a considerable length of bare stem that will show a disposition to throw out roots; if in the summer, when these appear, a little Sphagnum Moss be tied round the stem just under the leaves, the roots will quickly push into it, after which the crown may be cut off directly under the roots, placing

it in a pot proportionate in size, and treating it as advised with the smaller crowns, where it will soon get established. The stool that remains will push up several growths, as there is a dormant eye at the point where each leaf has been produced. These can be either taken off and grown singly in pots, or may be allowed to remain intact. In the spring, just as the plants are beginning to grow, they should be turned out, removing as much of the old worn-out soil as can be got away without breaking the roots; and when they have occupied pots as large as those above mentioned, they may be placed in the same with fresh soil.

The *Ataccia* is but slightly troubled with insects, its sap appearing to be of too acrid a nature to be congenial to their tastes. Thrips may sometimes, though very rarely, make their appearance on the backs of the leaves, and may easily be destroyed by syringing. Should green fly be troublesome, it is best dealt with by fumigation. T. BAINES.

PRIMULA ALTAICA.

THE frequent references to this *Primrose* recently made in these pages have induced Mr. Badgery, of Birmingham, to search for some information respecting it in earlier publications, and he finds that it was exhibited at one of the Royal Horticultural Society's meetings on the 20th of February, 1849, when it is spoken of as follows:—"Among the subjects of exhibition perhaps the greatest novelty was a scapeless *Primrose* in a pot, covered with beautiful orange-eyed purple flowers of permanent character. This was exhibited by C. J. Darbishire, Esq., Rivington, near Bolton, who found it growing on grassy land, which had recently been cleared of brushwood, in the neighbourhood of Kawak, a quarantine station on the Asiatic side of the Bosphorus, near the mouth of the Black Sea. When found it was midsummer, and the plant was out of bloom, and Mr. Darbishire considered it to be only a common yellow *Primrose* until it blossomed in the following spring. It was stated that he had found it to be perfectly hardy, standing our winters well out-of-doors; but that, as it had a disposition to bloom early if the roots were taken into the house in the latter end of the year, it formed a beautiful and useful ornament to the conservatory during a dull and dark season. It was mentioned that its rich and delicate colour is only displayed to advantage, however, under bright sunshine, and that, when grown freely, its foliage is very large and robust; that it is a profuse bloomer, and that it possesses a slight but delicious fragrance. It was stated to be not different from *P. altaica* of the Russian botanists, and it was awarded a Knighting medal." Now, assuming that this *Primrose* was the true *Primula altaica*, it is evident that the description agrees exactly with the variety which we have of late commonly known under that name, but, if it be possible to show that the authorities of the Royal Horticultural Society of 1849 were wrong, it would help to solve the difficulty if the *Primula altaica* of the Russian botanists could be either produced or exactly described. Whether that or something else, I think the modern variety has every claim to be considered as a distinct species from *Primula acaulis*, it having many distinct and divergent features. I have now in flower a purplish-red *Primrose*, of somewhat irregular form, with a well-defined lemon-coloured eye that has been sent out by a well-known firm as *Primula altaica*; but such is the uncertainty that hangs over its identity that I hesitate to accept it as such. I should think that amongst the readers of THE GARDEN there must be some able to settle this matter satisfactorily. A. D.

SWEET PEAS FOR THE GREENHOUSE.

ABOUT the beginning of March last year I filled two dozen 9 in. pots half full of common soil, which was mixed with a little rotten manure; I then placed a score of Sweet Pea seeds in each pot, and covered them over with about an inch of soil. They were then set in a cold frame and watered. By the end of a week the growth from each Pea was visible above the soil, and in another week they were 2 in. high. They were then potted into well-drained 8 in. pots, and returned to the frame. In a few days a further development was perceptible, and the additional soil was soon taken possession of; when about 4 in. high, about half a dozen branched Birch twigs 2½ ft. in height were put around each pot as stakes. To these the growths clung as they advanced; and by the time the tops of the stakes were reached, there was scarcely a twig visible—but, on the contrary, each pot was furnished with a pyramid of beautiful green leaves and abundance of flower-buds. As the flowers opened, they assumed one mass of the lovely shades found in well-selected colours of Sweet Peas. They were not only admired for their appearance in the

conservatory, but they charged the air with a delicious perfume. Quantities of bloom were cut from them for other decorations, and the great quantity of flowers which they produced was most surprising. After a long period of great beauty in the conservatory, they began to lose vigour for want of root-room, when they were turned out of the pots and planted in the corner of a border, where they made fresh growth and furnished plenty of bloom for cutting in autumn. After potting and staking, watering was all the attention they required. In the summer months they may be grown in the open air until they come into bloom. Since then I have often wondered why this lovely sweet-scented annual is not more generally grown in pots. Under favourable circumstances and with the assistance of a little warmth, I feel certain they might be had in full blossom at Christmas.—PRACTITIONER, in the "Gardener." [This is a very good idea, and easily carried out. The best way would, of course, be to sow in autumn and winter in cold frames, introducing the plants into a sunny house from time to time.]

Destructive Effects of Gas Tar on Plants.—Mr. Renny showed, at the last meeting of the Royal Horticultural Society, leaves of Pelargoniums and Fuchsias killed by having been placed in a house which had been painted over with tar. Hard-wooded plants, such as Azaleas, were not hurt, nor Chinese Primulas. Among the Pelargoniums the tricolor varieties suffered most. The Hon. and Rev. J. T. Boscowan adduced other instances of a similar character.

Is Boiler-water Injurious to Plants?—Dr. Kellogg, of San Francisco, commenting on a note on this subject published in THE GARDEN of November 27, 1875, says:—"Not long ago the locomotive ran off the track at Mastick's Station, and the boiler was emptied. The exact area where the fluid fell is marked by an exceedingly rich vegetation, rendered more conspicuous by the poverty of the surrounding sand. The effect produced in this case is quite equal to so much guano spread over the ground." This he considers a sufficient answer to the question.

Apogonon distachyon Indoors.—Allow me to inform Mr. P. Grieve (p. 280) that I was aware that this aquatic plant was thoroughly hardy, but my aim was to recommend it for cultivation in small greenhouses attached to town residences. I go a step farther, and assert that the flowers on my plant—growing as it is in a confined space—are much larger than any I have seen on plants in the open air. My small specimen, which has now three splendid flowers on it remarkable for their size, exquisite perfume, and delicate beauty, can be enjoyed without going out to face the biting northerly winds that now prevail.—QUO.

Lycopodium denticulatum Indoors and for Bouquets.—This is a good time to fill a number of pots, pans, or boxes with this very useful Club Moss for purposes of indoor decoration. Although all Lycopods like moisture, yet they will not continue to flourish long unless there is free drainage. L. denticulatum may be grown in any light sandy soil—in fact, we have large breadths of it growing under a stage without any preparation at all, and we find it exceedingly useful to pull up by handfuls as a base for short-stalked flowers, such as Violets and Stephanotis, in low flat glasses. Pieces of this Lycopod are also very useful for forming centres for bouquets, the green sprays, peeping out from amongst the flowers, relieving their brilliancy. Small bits dibbled in thickly now will soon form dense masses.—E. HOBDAV.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Glass Houses with open Laps.—I have just had a stove house erected by Mr. Rendle. My gardener says the system of glazing admits so much air that he will not be able to grow stove plants in it. If any of your readers have experience on the subject, I should be very grateful if they would let me know the result.—S. C. D.

Scilla matralensis.—I had a large specimen of this bulb from Mr. A. Roezen, Oeverveen, near Haarlem, in November, 1874. It failed to bloom in a warm greenhouse, and I moved it into a much larger pot, as I found it was pot-bound in the former one. It has grown more vigorously this season, but does not seem inclined to flower. The greenhouse is warm and dry, with a southerly aspect, and the ordinary fire-warming apparatus. Any hints on cultivation would be welcome. According to Mr. Roezen the bloom should be magnificent.—JAMES C. ROSS, *Baldon Vicarage, Oxford.*

Sempervivum Donkelaari Indoors.—A few plants of this variety, if planted in a large pot or pan early in the summer, will make an exceedingly handsome group for winter decoration in a cool house. The plants reach a height of about 9 in., and turn their heads to the light all round, so as to form a perfect and compact mass of foliage. It is one of the handsomest and most effective of the taller varieties, and makes a capital companion plant to *Sempervivum canariense*, *arborescens*, and *arborescens variegatum*; also for *Echeveria metallica* and *E. metallica glauca*.—A. D.

SEEDS AND SEED-RAISING.

SEEDS are capable of enduring extremes of temperature, which would prove fatal to the living plants of which they are the product. The length of time during which seeds of certain plants will retain their vitality is uncertain, but it must in many cases be very considerable. Plants of the Raspberry, Gooseberry, and Strawberry have been raised from seeds contained in jam made from the fruit of these plants, such seeds having necessarily endured, for some considerable time, a temperature exceeding 212°, the point at which water boils. The great length of time during which some seeds will remain in the soil in a dormant condition, although to all appearance under circumstances favourable to germination, is very remarkable. Some twenty or more years ago the central parts of some large flower-beds here were planted with the common White Petunia (*P. nictaginiflora*), and notwithstanding that every season since those beds have been occupied by various other kinds of bedding plants, no season has passed during which an abundant crop of seedling Petunias has not appeared upon them, although the Petunias have never since that time been allowed to flower in them. Similar instances have been observed in the case of Verbenas, Heliotropes, Pelargoniums, and other species of plants. Although many kinds of seeds maintain their vitality apparently undiminished for a great length of time when buried at certain depths in the earth, yet, when harvested in the usual way, a gradual diminution of vitality at once ensues, and it is generally found that the newer the seeds are, the larger is the percentage that will germinate, and this percentage will be found to diminish with each succeeding season; and, as a general rule, few kinds of seed can be depended upon for a crop after the second year. With some kinds it is even unsafe after the first. I have never known a seed of the *Perilla nankinensis* to germinate if more than a year old, and this is also the case with regard to many others; while, on the other hand, seeds of the Pelargonium will germinate even in a green and apparently unripe condition, and the plants so produced will generally be found to be more robust than those from seeds more thoroughly matured. But, as luxuriant development is, to some extent, opposed to fertility, it consequently follows that in the case of such annual plants as the Melon and the Cucumber, old seeds, or seeds not less than two years old, are to be preferred to newer ones.

The seeds of some leguminous and other plants are encased in a somewhat hard shell or covering, which generally causes them to lie for a considerable time in the soil before they germinate; but growth may in most cases be greatly accelerated by pouring hot or even boiling water upon the seeds, and allowing them to remain in it for two or three days before sowing them. Very old seeds of various kinds, which would not, under ordinary circumstances, germinate at all, may sometimes be induced to do so by the application of certain chemical substances, such as oxalic acid, newly slaked lime, &c. The ordinary conditions, however, necessary to induce seeds to germinate are, exclusion of light, and maintaining a certain amount of moisture and heat, the latter, of course, varying in accordance with the requirements of different species. The seeds of many of our most common indigenous plants or weeds will germinate in soil at a temperature but little above the freezing point (32°); and it has been even asserted recently that seeds have been found to germinate in grooves formed by blocks of ice. An earth temperature, however, varying from 50° to 60°, may be considered as that most favourable to the germination of the seeds of plants indigenous to Europe, while a bottom-heat of from 70° to 80° or upwards will be necessary to start into growth seeds of plants which are natives of tropical countries. In this country it is found that the seeds of many flowers, as well as those of some culinary plants, will not germinate until the seed has attained a certain degree of warmth, or, if they do grow, the low temperature in which the embryo plants are placed generally proves very prejudicial, if not fatal, to them. It is, therefore, never advantageous, but frequently the reverse, to sow seeds even of the common garden Beet, which is a variety of *Beta vulgaris*, and a native of the south of Europe, earlier than the first week of April. Such a course is also to be recommended in the case of the Scarlet Runner and the

several varieties of dwarf Kidney Beans, &c., while the *Tropaeolum peregrinum*, or Canary flower, a well-known decorative climbing plant, being a native of Peru, and, consequently, tender, is commonly sown under glass in a slight bottom-heat, and planted out when the season is somewhat advanced, but even then it generally sustains a considerable check. It is found to answer better to defer the sowing of the seed of this favourite climbing plant until some time during the first half of the month of April, or until the soil has become somewhat warm, and then to sow it in the open air where the plants are intended to flower. A very considerable portion of seeds of all kinds when sown in the open air during dry weather either perish altogether or germinate irregularly, and are consequently exposed for a long time to the attacks of birds and mice. It is therefore always advisable in the case of large seeds, such as those of Beans and Peas, not only to steep them in rain-water for twenty-four hours or longer before sowing them, but also to pour abundance of water into the trench or drill prepared for them, and, as soon as the seeds are sown, to cover them up immediately. In the case of smaller seeds, such as those of the different varieties of the Brassica tribe—Lettuces, Endive, &c., whenever it is necessary to sow during dry weather, the seeds should be previously steeped in water and afterwards partially dried, in order that they may be evenly sown; the soil, too, intended for their reception should be well watered before the sowing takes place. And when the seeds have been gently pressed into the moist soil, and covered with it (the covering, of course, varying in accordance with the size of the seeds), the surface should be made smooth and level, and at once covered with bast mats, or pieces of frigi domo, or any similar material which will combine the effects of excluding light, protecting the seeds from birds, and retaining to some extent the moisture in the soil; under such circumstances the seeds will generally germinate freely, and care must afterwards be taken to remove the covering soon after growth has taken place, selecting, if possible, a showery or dull day for effecting this removal. The various kinds of flower seeds sown in the open air, such as those of Mignonette, should, in order to ensure success, be treated in this manner. Very many of these, however, are usually sown under glass, and are consequently more under command than out-of-doors. It is, however, necessary to exercise care in the sowing of tender annual and other flower seeds under glass, inasmuch as many of them are so exceedingly small that they scarcely admit of any covering in the form of soil. Gloxinias, Begonias, Calceolarias, and many others belong to this class, and should be sown in well-drained pots or seed-pans, in light soil, containing a portion of silver sand, but the surface should be made perfectly smooth and level, and should be moistened through the fine rose of a watering pot. On this surface the seeds should be sown, and pressed gently down; and they should be covered with a portion of soil, more or less, according to the size of the seeds sown. Where they are very small a mere sprinkling of silver sand will be sufficient; or, this may be omitted altogether, and the surface of the pot or pan merely covered with a piece of glass, which should be shaded with whitewash, or have a piece of paper placed over it, and as soon as the seeds have fairly germinated a little air should be admitted by raising one side of the glass and gradually exposing the plants to the light; or the surface of the pots or pans containing the seeds may be covered with a thin layer of damp Moss, which must be removed as the plants develop themselves. The best structure, however, in which to sow the seeds of tender annual and other plants is a close frame or pit, as free as possible from drip, and in which there is a slight bottom-heat and an atmospheric temperature of from 60° to 65°. This should be covered with a mat or cloth so that light is nearly or altogether excluded, and as the germination of the various kinds of seeds sown will not be simultaneous, each pot or pan should be removed as soon as the young plants make their appearance, and gradually inured to the light before etiolation or blanching takes place.

If a course similar to what it has here been attempted to describe be pursued, we should probably hear fewer complaints of the worthlessness of flower and garden seeds than we sometimes do. That the necessary conditions for their healthy

germination are not always understood is proved by the following statement. A purchaser of a packet of the herbaceous or large-flowered *Calceolaria* says:—"I sowed the seeds in a flower-pot, which I placed in the warmest part of a sitting-room window, and watered it daily, and, for the sake of additional warmth, I invariably placed the pot with its contents near the fire-place at night, and yet the seeds did not grow." The herbaceous *Calceolaria* has, by the practice of a careful system of selection, arrived at a state of great perfection, and a packet of seed generally produces such a varied assemblage of finely-formed and beautiful flowers that the practice of raising them annually from seed is usually followed, and the old plants are discarded as soon as they are out of bloom. But although this plant is a native of Peru, the seeds are nevertheless, exceedingly impatient of heat, and refuse to germinate in a high temperature, and as the end of April or the early part of May is the best time at which to sow, the pot containing the seeds should be placed on the north side of a wall and covered with a hand-glass, or even if the pot be merely covered with a piece of glass, the seeds will generally germinate very freely.

P. GRIEVE.

THE VARIOUS RACES OF GARDEN FUCHSIAS.

By W. B. HEMSLEY.

THE occasion of presenting our readers with an engraving of this remarkable variety seems an appropriate one for giving a few historical notes on the introduction of different species, and the progress of hybridisers in raising new varieties and new strains. In the first place, a few words on the distribution of the fifty or sixty species of this elegant genus. With the exception of three or four, they are all natives of Central and South America, growing in the temperate regions of the mountain ranges from Mexico southward, and gradually descending until, in the extreme south, their home is near the sea-level. The remaining three or four species are only found growing wild in New Zealand. One of these, *F. excorticata*, introduced in 1824, is a tree of considerable size, occasionally attaining the extraordinary height of from 30 ft. to 40 ft., with a trunk as much as 3 ft. in diameter. The others are slender trailing shrubs, with small leaves. *F. procumbens*, of quite recent introduction, represents this section. They have alternate leaves, no petals, or only very small ones, and the flowers—in *F. procumbens* at least—are erect, a character confined, so far as I am aware, in the American species to the varieties of *F. arborescens*. The first publication of the name *Fuchsia* was by Plumier, a French botanist, in his "Nova Plantarum Americarum Genera," which appeared in 1703. But it is a noteworthy fact that nobody has succeeded in identifying the plant figured and described by him under the name of *Fuchsia triphylla* with any known species of the genus as now understood; and Burmann, who, about half a century later, published Plumier's inedited plates, does not clear up the obscurity. The plant figured has altogether the aspect of a true *Fuchsia* of the splendens type, but it is figured and described as having only four included stamens. It is quite possible that it may be a plant unknown to modern botanists. The first undoubted *Fuchsia* was figured and described by R. P. L. Feuillé, in his "Journal des Observations Botaniques, etc.," iii., p. 64, plate 47 (1725), under the name of *Thilco*, the Indian appellation of the species in question. This was found by him on a mountain slope in the extreme south of Chili, and appears to be one of the varieties of *F. macrostema* (*F. magellanica*). It is singular that his plant has a five-parted disposition, which, however, may be regarded as an accidental occurrence familiar to cultivators of *Fuchsias*.

Introduction of Living Fuchsias.

Messrs. Lee and Kennedy, of the Vineyard Nursery, Hammersmith, appear to have first cultivated *Fuchsias* for sale in this country, and indeed in Europe. It is uncertain whether the true *F. coccinea* or *F. macrostema* (*magellanica*) was introduced first; but it is now certain that both of these species were in cultivation in this country towards the end of the last century—about 1786 to 1789. It would occupy too much space to adduce proofs of this statement here, and refer all the published plates to their respective species. A few years

ago Dr. Hooker discovered the true *F. coccinea* at Oxford, and gave a plate of it in the "Botanical Magazine" (5740), pointing out its distinctive character from *F. macrostema*, commonly known as *coccinea*. I believe, however, that *F. macrostema* was introduced in 1788 and *F. coccinea* in 1789. The former is figured under the latter appellation in the "Botanical Magazine," t. 97, and the latter in Salisbury's "Paradisus," under the name of *elegans*. The next species we read of in cultivation is *F. lycioides* (rosea), in Kew Gardens, in 1796 (Andrew's "Repository," t. 120), followed by several varieties of *macrostema*, and the species *excorticata* and *arborescens* in 1824, *microphylla* in 1827, *fulgens* in 1830, *corymbiflora* in 1840, *splendens* in 1842, *macrantha* in 1845, and *seratifolia* in 1847. I may add here, that Sweet appears to have been aware of the distinctness of *coccinea* and *macrostema*, for, under pl. 216 of the second series of his "British Flower Garden," he says that the varieties of the latter are much harder than the former. There is no doubt, I think, that Salisbury is right in his statement that *F. coccinea* is a native of Brazil, as it is almost identical with the plate of *F. montana* in St. Hilaire's "Flora Brasiliensis." This would account for its early disappearance, leaving the harder Chilean species to bear its name.

Early Natural Varieties.

Hitherto I have found no record of any new varieties previous to 1820. Among the first were two or three wild varieties of *macrostema*, imported from Chili; of these *F. conica* of Lindley was introduced in 1824, and *F. discolor* of Lindley was raised in 1830 from seeds collected by Mr. Anderson (who accompanied Captain King) at Port Famine, Falkland Islands. This is described in the gardening journals of that period as the hardest of all Fuchsias, never being injured by the winters of Scotland even; it was raised by Mr. Lowe, of Clapton, and bore the name of *F. Lowei* in gardens. The first Fuchsia recorded as of hybrid origin, so far I am aware, is *F. globosa*; but it has the appearance of being a mere seminal variety. In Loudon's "Gardeners' Magazine" for 1832 I find the following passage:—"F. globosa (Hort.) is said to have been originated by some gentleman's gardener from seeds cross-impregnated between *F. conica* and *F. microphylla*." In the second volume of "Paxton's Magazine," in reference to this variety, the editor states that D. Don says it was raised by Mr. Bunney (presumably of the Kingsland Nursery) from seeds of *F. conica*. Soon after Mr. Silverlock, of Chichester, raised *globosa elegans*—a variety with longer pedicels—from *globosa*, but it was not known by what variety it was crossed. In 1838 Lowe's *Atkinsoniana*, an improved *globosa*, was sent out. The introduction of *F. fulgens*, *cordifolia*, and other species, opened a wider field for hybridisers, and new strains of varieties and improved varieties followed each other so fast that Loudon, Paxton, and other writers of the time were constantly appealing to raisers not to flood the market with varieties scarcely appreciably different from those already known. In "Loudon's Magazine" for 1839 several hybrids between *fulgens* and *grandiflora* (one of the *macrostema* set, raised by T. Colley, Hope Nurseries, Leeming, Yorkshire), are

described. Among them *majestica*, flower, including foot-stalk, $4\frac{1}{2}$ in. long, and 2 in. across; *fulgida superba*, flowers $3\frac{1}{2}$ in. long, very compact, foliage large dark green; *multiflora erecta*, a neat grower and profuse bloomer, with good foliage. Day's *racemiflora*, raised by Mr. Dick, gardener to A. Annesley, Esq., Bletchington Park, between *fulgens* (female) and *grandiflora* (male) was awarded the prize for the best seedling at the Oxford Show in 1840. The same year Poutey's *tricolor* appeared; this was remarkable for its fine colouring, the sepals being tipped with green and the petals of a rich purple. A handsome hybrid, raised by Standish, between *fulgens* and *globosa*, was figured in the "Botanical Register," 1840, t. 2, and the same nurseryman flowered *F. corymbiflora* the same season. In "Loudon's Magazine" the latter is said to be as hardy as any Fuchsia. *F. arborescens*, singular in its terminal panicles of small erect flowers, does not appear to have entered into any of the hybrids raised either then or since.

An erect-flowering Fuchsia.

Writing on the subject of hybridisation Donald Beaton says—"F. arborescens will not receive the pollen of the *macrostema* set, whilst *excorticata*, impregnated with the pollen of either *F. conica* or *globosa* will produce facsimiles of *discolor*." This last assertion would seem to be based upon some error. In 1842 Messrs. Henderson, of Pine-apple Place, obtained a Banksian medal for *F. Money-penny*, a luxuriant grower, with handsome leaves and very long spreading flowers, of a most brilliant red colour, raised by Morris Todd, of Rolvenden, Kent. The same season Messrs. Lane, of Berkhamsted, gained a similar distinction for their *F. Lanei*, a variety described as possessing the elegance of the older, without the coarseness of the modern kinds, the flowers being somewhat of the shape of the old *globosa*, but more expansive and singularly large; sepals bright crimson, petals of a light purplish hue. About this date a real advance was made by Pince (1842) with his *F. exoniensis*, a hybrid between *F. cordifolia* (female) and *F. globosa* (male), having long spreading flowers, calyx rich crimson, and corolla deep violet-purple; *F. cordifolia* not being so well known as *fulgens*, it may be observed that it approaches *F. splendens*, but it is less hairy, and has broad heart-shaped leaves. The same year, Mr. Cripps, of Tunbridge Wells, sent out *F. Venus Victrix*, raised by Mr. Gulliver, gardener to Rev. S. Marriotti, Horsmonden, a variety that has given birth to many others, and even now is regarded as a valuable one for purposes of crossing, and it is known to most young gardeners. In 1843 a list of good hybrid Fuchsias is given in "Paxton's Magazine," which include besides those mentioned—*conspicua-arborea* (Cattleugh), *Stanwelliana* (Purdie and Merrilies), *Eppsii* (Epps), *formosa-elegans*, *Frostii*, &c. Smith's (Dalston) Queen Victoria was another acquisition of this period. It was a fine variety, with pink green-tipped sepals, and crimson purple-tipped petals. In 1844, Standish raised the famous trio of varieties figured in "Paxton's Magazine," 1844, Vol. XI., plate 31, namely, *Attraction*, *President*, and *Colossus*. The first has short reflexed sepals and very large deep purple petals; and the other two have green-tipped sepals. They were the issue of *formosa-elegans* fertilised by *corym-*

biflora. Another early variety deserving of mention is the old Dominiana, supposed to be a cross between *F. scarrifolia* and *F. spectabilis*. Not to make this sketch too long, especially as I am still unable to present it in a compact and connected form, I will pass on to 1850, the date of the appearance of the first double-flowered varieties, with a violet, blue, or red corolla. The *F. duplex* and *F. multiplex* of Story were superseded by Henderson's *F. Hendersoni* in 1852, and in 1853 Turner's *F. grandis* exhibited a great improvement on its forerunners, to be in its turn supplanted by still more perfect varieties, the history of which is too recent to need recapitulation here. Coming to the varieties, single and double, with a white corolla, Mr. Story again has the merit of initiation with his Mrs. Story, Lady of the Lake, Queen Victoria, Snowdrop, &c., followed by Lucombe and Pince's Florence Nightingale, &c. That all these varieties have almost or quite disappeared in favour of superior ones is notorious. In 1850 Mr. Story sent out the first *Fuchsia* with a striped corolla, followed by Banks's *F. striata perfecta* in 1858, and Williams's *F. striata perfecta* in 1870. The latter is believed by some writers to be the same as Carl Holt, a variety of German origin. Mr. Bull's Gipsy Queen, a double-flowered striped variety, appeared in 1865, and Mr. Smith's Striped Unique in 1868. Finally there are the varieties with variegated foliage, the first of which—a very poor one by the way—was raised in Belgium. This was succeeded by several others, none of great merit until 1872, when Milner sent out his Sunray. The variety, of which an engraving is given on page 285, made its appearance in French gardens about 1868, and is said to be nearly related to *F. globosa*, from which it differs in its pale rosy colour and erect flowers.

In conclusion I may mention the introduction of some of the distinct tribes of American *Fuchsias* not already specially alluded to. First there are the miniature species, *F. microphylla* and *F. thymifolia*, both figured in Sweet's "Flower Garden" for 1835, of which some garden varieties, scarcely superior to the types, have been offered from time to time. *F. cylindracea*, a species of the same section, introduced in 1837, is quite unisexual; they are all natives of Mexico. Another South American group is distinguished by having alternate leaves, no petals, and being usually of epiphytical habit. One of these, *F. macrantha* (Bot. Mag., t. 4253), was introduced by Messrs. Veitch, in 1845, and exhibited by them in 1846. This is a very handsome plant, with large cordate leaves, and flowers 4 in. to 6 in. in length, but being of difficult cultivation it has disappeared from our gardens. I have recently described several new species of this section in the "Journal of Botany." Finally, there is the attractive little *F. procumbens* from New Zealand, with erect flowers, and a very large pulpy fruit.

Hedge Cutters.—In THE GARDEN of October 10, Mr. T. Barnes described a Dunse Switch Hook and a hook for cutting strong hedges; would you kindly let me know what English firm would supply me with these hooks, and, if possible, the price?—GERMAN. [The Dunse Switch Hooks, which are only intended for cutting one season's growth of hedges, are made at Dunse, in Scotland. Any of the principal nurserymen or seedsmen in London or in the large provincial towns, who sell garden tools, will supply them. I used to pay 7s. 6d. for one in the north of England. The stronger hook, with the bent blade for cutting hedges when the wood has got an inch or two in thickness, can be made by any intelligent smith who can temper edged tools without snipping or burning in the edge; these I used to get made in the neighbourhood in which I happened to reside. The cost was about the same as that for the Dunse implement.—T. BARNES.]

Typa as a Fibre Plant.—This marsh plant, commonly known in France as the *Massetto*, and comprising three varieties, is found to yield a fibre capable of being utilized in a valuable way for textile purposes. The plant grows in a wild state and very abundantly, in streams of water, ponds, &c., and reaches to a height of about 6 ft. Heretofore it has been employed for seating chair bottoms, for thatching, &c., in the same manner as straw. The mode of extracting the fibre from the leaves, after the latter are cut and dried, consists simply in boiling them for several hours in an alkaline solution, and afterwards dressing them in a mill or under rollers, the process being then completed by washing. A yellowish paper is made, worth about 3½d. per lb. The fibre will also prove useful, it is thought, for fabrics and for cordage, being considered equal to hemp

THE FLOWER GARDEN.

SPRING PRUNING ROSES ON THE MANETTI STOCK.

MUCH has been said and written about growing Roses on the Manetti; some prefer it as a stock to the Briar. For pruning Briar Roses grown as standards or half standards, we have certain fixed rules laid down which have been proved by experience to be successful. As regards pruning Manetti Roses, opinions differ, almost every grower appearing to have a system of his own. One thing is certain, that it is always safe to cut clean away to the base any shoots which may cross each other, dead wood, and thin weakly twigs; from neither of the above is a good Rose ever produced. Some varieties on this stock (I am speaking of Hybrid Perpetuals) are very vigorous, making shoots in one season from 9 ft. to 10 ft. high; very often these shoots do not bloom, or if they do it is late in the summer; other varieties make shoots from 2 ft. to 4 ft. The latter may be pruned to about 18 in. above the ground. The longer shoots may be pruned down to 3 ft., and any shoots on the same stool may be cut down to 2 ft. Roses on the Manetti bloom much earlier than those on the Briar; therefore they should not be finally pruned until about the first week in April. If pruned earlier, the young shoots produced in April are often cut to pieces by the frosts and easterly winds which generally prevail in the spring. When such is the case, it is better to cut back again to a firm plump bud which has not been thus injured. If the amateur who is growing for exhibition find his Roses too early, he should cut back to an eye or two below the topshoots, the effect being to delay the blooming a week or ten days. One thing it is necessary for him always to remember, that the lower he prunes his Manetti Roses the longer they will be in coming into bloom; it is plain, therefore, that a medium course is best. If one were to cut a long rod down to 6 in. it would probably produce one long rod again, which would not bloom in time for the summer exhibitions. Should a large quantity of Roses for bouquets be required, it is a good plan to pull the long rods down to a horizontal position, merely cutting off a few inches at the top; the rod must be fastened down by means of small stakes driven into the ground, to which it must be tied. This operation should take place early in April; in the middle of May it will be found that the long rod has broken at every joint; the rod should now be raised, and fastened to a stout stake. After it has done blooming, it may be cut down to within 1 ft. of the ground, when it will push out several strong shoots, which will flower in the autumn, and cause the tree to assume the bush form. Dwarf or bush Roses on the Manetti must be well manured, mulched, and watered, as recommended for standards. They will bear rougher treatment than standards, and they are not so fickle as to soil, growing and flourishing where a Briar Rose would perish; but they should not, on that account, be neglected, particularly where fine blooms are required. Supply them regularly with liquid manure throughout the growing season in the same manner as suggested for standards, and keep the foliage clean and free from grub and aphid by means of a constant use of the syringe. After the first series of blooms are exhausted, the plants must be looked over and the shoots shortened to a good eye. It will be found that this process will greatly assist them in producing their second display of flowers in the autumn, and is far better than leaving them to chance.

HENRY TAYLOR.

Geometrical Gardens and Old Houses.—We find in a contemporary the following:—"As the house is four centuries old, geometrical beds would be appropriate." We trust that all who care for natural beauty in a garden will discountenance this error. There is, of course, no true reason why the earth, and flowers, and Grass, should be converted into a carpet pattern before a house four centuries old than any other. There are many English houses four centuries old that look much more beautiful with the level Grass before them than they could be made by any amount of expense devoted to geometrical gardening. There are, indeed, not a few examples of fine old houses, the effect of which is, we think, marred by the formation of the old Dutch and other kinds of very artificial and very barbarous gardens.

Dell's Black-leaved Ornamental Beet.—This is now (March 16) very effective in the spring garden, its fresh shining foliage being of the deepest hue and very conspicuous, inasmuch as it has no rival among fine-foliated hardy plants. It contrasts admirably with early-flowering bulbs, Golden Feather *Pyrethrum*, and the ordinary early-flowering plants usually employed for furnishing spring gardens, many of which, having white or yellow flowers, are considerably improved by being contrasted with the metallic foliage of this Beet. Not the least advantage belonging to plants like this is

that they do good service both in spring and summer. For spring display this Beet should be planted deep enough to enable the roots to be entirely covered with mould, when the old foliage will continue effective until cut down by sharp frost; but it commences to grow again so early that the young leaves are in good condition for contrasting with the earliest Crocuses and other plants of that description. It also possesses the great advantage of being easily raised without the aid of a glass structure. Seed sown on a sheltered border early in April will be in good condition for transplanting in May, or if the beds or borders be unoccupied, it may be sown where it is intended to remain, and be thinned out to the required distances apart. For ribbon borders in straight lines, few plants are more effective either as regards uniformity in height or intense colouring.—J. GROOM, *Henham*.

THE SWEET WOODRUFF.

(*ASPERULA ODORATA*).

THIS little wood plant, abundant in some parts of Britain, is worthy of some attention in the garden and shrubbery, especially in localities where it does not occur wild. Many would like to cut and preserve its stems and leaves for the sake of the fragrant hay-like odour which they give off when dried; and in May the pure white small flowers, profusely dotted over the tufts of whorled leaves, look very pretty. It may be seen covering the ground with its carpet of green frosted over with white, in some of the College Gardens at Oxford, and it is one of the many plants that may be allowed to

cover the earth in a shrubbery where the barbarous practice of annually digging and rooting up the borders is not resorted to. It is sometimes used as an edging to the beds in cottage gardens, the odour filling the air. It is, however, as a wood or shrubbery plant—as a companion to the Wood Hyacinth and the Wood Anemone—that it will be most at home.

PROPAGATING ALPINE PLANTS.

BESIDES the provision made by Nature for the increase of plants by means of seeds, to which I especially alluded (see p. 240), there are of necessity other modes and processes by which this result may be attained. Being chiefly of an artificial character, these are specially applicable in the case of cultural variations, whereby choice varieties may be perpetuated in their true character. This result, as a rule, cannot be depended upon in the ordinary process of reproduction by means of seeds. Again, there are many plants, and some, too, of the most charming and interesting kind, that will not produce seeds in our variable climate, or do so in such a meagre way as to render this mode of reproduction almost valueless. A few remarks, therefore, on this subject at this season, when they can be readily turned to practical account, may be useful. First, let us deal with modes purely artificial, as they are the most important. Every one who has had any practice in gardening, whether as amateur or otherwise, knows that plants are increased by means of cuttings—that is, by removing short branches, cutting the same part below a leaf-joint, and inserting them in soil to which a considerable mixture of silver or other sharp sand has been added. At first sight the process may appear exceedingly simple, but there is something more involved in it than the mere mechanical process necessary to success, namely, the condition of the plant and the time at

which the operation is performed; on these successful results hinge much more than on the mere mechanical process. In what, then, do those favourable conditions consist? At this season, the hitherto dormant energies of all plants are by the increasing action of the sun and various other equally important vernal influences in process of stimulation into active growth. This is shown by the production of numerous young shoots, which, if left undisturbed, become flower-bearing stems during summer; and it is just at this time, or a little later on, dependent of course on the season, that these young shoots should be removed with a sharp knife and a careful hand, and placed in a pot of sandy soil, not hard pressed—as would be necessary for hard-wooded cuttings—but of loose texture, depending more on a good watering for its consolidation after the operation has been performed, and finally plunging the pots in a close frame with a gentle bottom-heat. All, then, that will be required is to keep the frame close for a few days, shading, of course, from the sun, but no more than is absolutely necessary to prevent the leaves flagging; light, with a supply of moisture in the soil below, will assist to develop the foliage in a healthy state one end of the cutting, and will speedily be followed by roots at the other. After, say a week, it will be advisable to remove the glass covering for half-an-hour in the morning, sprinkling the cutting pots with a fine-rosed can, if they are at all dry on the surface, the period of exposure being gradually extended; by this means, in the course of five or six weeks, good pots of healthy vigorous plants will be ready for removal from the frame to full exposure, with scarcely a single death amongst their occupants; and be it noted that this result can be attained in the same satisfactory manner at no other season of the year.

The number of plants, to which the foregoing remarks apply, are almost legion; in fact, wherever cuttings can be obtained. Sometimes it will be necessary to bare the crown of the plant, as in the case of Delphiniums, in order to get the fleshy shoots off with a bit of hard heel to them. No better general illustration can be given than is represented by the Dahlia, with the propagation of which every one is familiar. Apply the same general principle, and a large amount of success must follow. So much for the time; a word now as to the conditions. If healthy young plants be desired select your cuttings from a healthy stock—the more vigorous the young growth the better. With the view of obtaining these conditions earlier in the spring than Nature, in her ordinary course, will permit, it is an excellent plan, where the plants to be operated upon are grown in pots, to bring them into a warm greenhouse in February, and place them on a shelf close to the glass; by this means the stimulated vital energies of the plants will become early excited, and young plants thus obtained will form good blooming tufts during the summer and autumn. All the rarer Campanulas will, under these conditions, strike as freely as a Lobelia, and may be increased to an almost unlimited extent.

The growth of many Alpine plants is so dense that they are readily increased by division of the crowns. This process with very early-blooming plants should be deferred until after the flowering season is over, succeeded by a short period of rest, after which a fresh growth naturally follows; before this becomes too advanced the process of division should take place; this will be in the month of June or July, the young plants so manipulated requiring only the shelter of a close frame and a little shading from bright sunshine for a few days. For summer and autumn flowering plants, the present time is the best, and from these it is advisable, as the regular process of re-potting the general collection of Alpine plants will have commenced, to shake off all the old soil. Thus the operator is enabled to see exactly how to make the divisions to the greatest advantage; this is always better than thrusting a knife into the heart of the plant at random. One maxim I should like thoroughly to establish is that, except in the case of some of the mossy Saxifrages, never attempt to subject a plant of any value to the severe ordeal which this process necessarily involves after the beginning of October at the very latest. My experience is that additions made to the collection by a late autumn tour, when division must necessarily take place, are far from satisfactory, either to the donor or the receiver, and not unfrequently result in the plant being

lost to both. I have before especially excepted the mossy section of the Saxifrages; these appear to appreciate the divisional process in the autumn and in any garden subjected to the ravages of the white larvæ of the Otiorynchus. It is a wise precaution to insert portions of the various species about the month of October in small pots, so that, in the event of the old plants being attacked, you may have these to fall back upon. My advice to all who wish to maintain a collection of Alpines—and the same remark applies, to some extent, to herbaceous plants as well—is to secure yourself from losses by means of duplicates in small pots; this process may be attended with a little trouble, but the result is amply compensatory.

JAS. C. NIVEN.

Botanic Garden, Hull.

Flowers for the Woods.—Under this heading (see p. 253), a correspondent recommends, among other things, Christmas Roses and Auriculas as rabbit-proof. It may save trouble to some of your readers if you let me tell them that out of a quantity of Christmas Roses (*H. niger*) and Auriculas with which I adorned a woodland bank not one has survived the appetite of the rabbits. Most of the Lily family are rejected by them, including Daffodils, Tulips, Snowdrops, Snowflakes, Lilies, Day Lilies, Asphodels, and others, and they cannot be too extensively planted; but even in that tribe the Crocus (which is also named in the article in question) is greedily devoured. I gave—in an early number of your paper (see pp. 9 and 88, Vol. I.)—a list of all rabbit-proof trees, shrubs, and flowers then known to me, and I regret that, though keeping a watch upon the subject, I have not been able to add a single species to the list of four years ago.—SALMONICERS.

Flint Edgings.—For gravel walks or for flower-beds flints form excellent edgings. If selected of uniform size, when properly laid they have a neat appearance, and for a kitchen garden they are, perhaps, preferable to Box or any other live edging, inasmuch as they neither harbour slugs nor insects of any kind. In laying them, the sides of the walks should be levelled as if for an edging of Box. The line should be stretched upon them, and they should be beaten well down with the back of a clean spade. This will leave a well-defined mark, and to this the flints should be laid and beaten gently into the soil with a wooden mallet. The necessary portion of soil should then be thrown out and replaced by gravel, which should be spread close up to the flints, in the same way as is usually done when a live edging has been planted. Should any of the flints become displaced they may be easily put right again, and, as a matter of course, they never wear out.—P. GRIEVE, *Culford Hall.*

Christmas Roses.—In reference to the note which you have published on Hellebores (see p. 260), allow me to say that I should like to see Hellebores abachicus properly settled. The only doubt I have is that M. Boissier describes *H. abachicus* as having several leaves, while I find only one leaf to each branch of the root-stalk; but there is certainly only one leaf to each branch of the root-stalk in *H. antiquorum*, *olympicus*, and *guttatus*, while Boissier describes them as having two leaves. I suspect the character is worth nothing. *H. atrorubens* (true), *H. purpurascens*, *H. cupreus*, and *H. odoris*, I believe to be all varieties of one species; the last (*odoris*) I do not think is in cultivation in Britain. *H. antiquorum* and *olympicus* I have no doubt are but one species. *H. guttatus* is, I believe, quite distinct from *abachicus*, though I see one of your correspondents thinks them the same.—J. T. B.

—“J. T. B.” (p. 260) says that the Helleborus *niger major* is *H. altifolius*. This I have heard before, but not having Heyne's description of *H. altifolius*, I could not verify it. Can “J. T. B.” send Heyne's description and so settle the question? I cannot think it is *H. abachicus*; at least, I cannot reconcile it with Branne's description of that species. As to *H. niger angustifolius*, I feel very sure that it is the same as Sweet's *niger vernalis*—see Sweet's “British Flower Garden,” second series.—HENRY N. ELLACOMBE, *Bitton Vicarage.*

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Ostrich Feather Fern (*Strathiopteris germanica*).—For rich shady glens or shrubberies, fern, if any, ferns are finer than this. It forms noble circular crests of great elegance and beauty 3 ft. across, and fresh crowns are rapidly formed from runners at the root.—J. G.

Hepatica rubra and others.—I have a small plant of *Hepatica rubra* in flower, and find that it has the same rich red hues of colour that are seen in the single red form shown by Mr. Wilson at South Kensington on the 1st. of March. It is really a charming variety, and when abundant will make a lovely addition to our hardy spring flowers. We shall soon, I think, be able to enumerate at least a dozen distinct kinds of *Hepaticas*, as I believe that I have three distinct shades of blue, besides *H. angulosa*.—A. D.

PLATE XIII.

NEW DOUBLE POINSETTIA.

(*POINSETTIA PULCHERRIMA PLENISSIMA*.)

Drawn by H. NOEL HUMPHREYS.

THIS strikingly beautiful plant first flowered in Europe in December last, and we may safely assert that it has more than fulfilled the highest expectations entertained concerning it. Our illustration, which represents the inflorescence half its natural size, gives such an excellent idea of the colour and disposition of the bracts as to render minute description unnecessary. More than forty years have elapsed since the old *P. pulcherrima* was introduced to our gardens from Mexico, and no other plant—no, not even the gorgeous Orchids from its own habitat—have equalled it as a winter-blooming decorative plant; brilliant, however, as it is, it has certain drawbacks—it is thin in the centre, and the bracts radiate like the spokes of a wheel all in the same plane, a circumstance which gives to the inflorescence a certain amount of flat stiffness. In the new double form this fault is wholly obviated; we have a head of bracts equally large and equally brilliant, but we have a branched inflorescence consisting of a much greater number of bracts, all of which are arranged, as shown in our drawing, in the form of a rosette. As to the vigour of the plant, it is equally strong and free in its growth as the type, and we are told it is quite as easy of cultivation. The head is composed of seven or more stiff branchlets—most of which are set in a whorl round the base of a centre one, which projects several inches above the others. The whole produce no fewer than fifty or sixty bracts; they vary from 6 in. to 8 in. long, and several are 2½ in. broad. The bottom ones, being the larger, droop gracefully from their weight, and those which fill up the centre, being smaller, are less drooping, until in the centre of the head they are nearly erect, the whole forming a bouquet of the most brilliant glossy scarlet, not less than 16 in. across; it is rounded, too, fully as much as large bouquets generally are, and it lasts longer in a fresh condition than the single kind. When the striking effectiveness of this plant is seen, it cannot fail to find a place wherever winter decorative plants are in request. It is now over three years since we first directed attention to this plant (see THE GARDEN, Vol. IV., 1873, p. 143); it had then just been discovered by M. Benedicto Koezi, who found it in May in that year in a small Indian village in the Mexican State of Guercero, and dried specimens of it gathered at that time are now in the hands of Messrs. Veitch & Sons, of the Royal Exotic Nursery, Chelsea, who also hold the entire stock of living plants of this brilliant novelty. When M. Roelz first sent home the specimens referred to, he forbore to describe the plant because, as he observed, no botanist or florist would trust his description or believe that the plant was so gorgeous.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Bedding Plants.—The propagation of all bedding plants should be now pushed on as fast as possible, remembering that it is in all cases far preferable to have a surplus at planting-out time than a deficiency. Bedding Pelargoniums that were struck last autumn and wintered in stove-pots should now be potted singly in good rich soil that will push them forward before they are wanted for planting; they should have 3-in. or 4-in. pots, according to their strength, and, as soon as potted, they should be kept rather close to encourage them to grow.

Tomatoes.—A little Tomato seed should now be sown, as when the plants are large and strong at planting-out time, they will fruit much earlier and produce a correspondingly greater quantity than if young and weak when planted. Sow the seed in a shallow pan filled with two-thirds loam to one of leaf-mould and sand, covering the seeds lightly and placing them in a warm frame orinery at work; when they are large enough transplant singly into 3-in. pots, giving them more room as they require it.

Herbaceous Borders.—As soon as forked over, and the requisite manure has been worked in, Sweet Williams, Foxgloves, Carnations, Pinks, Phloxes, Pentstemons, Chelones, Delphiniums, Lychnis, Anemones, Mimulus, and others of similar character that

have been raised from seeds, cuttings, or layers, and have since occupied nursery-beds, should at once be transferred to the borders where they are desired to bloom. If their removal be delayed too long, the season's flowering is seriously injured. By those whose collection of herbaceous plants is so limited as not to include more than a few species, the White Everlasting Pea (*Lathyrus latifolius albus*) should be grown on account of its being so useful for cutting at a time when white flowers are not over-plentiful. The planting of Ranunculuses of the double Turban kinds should no longer be deferred, but if put in now they will in most situations do quite as well as if they had been planted sooner, especially in such a season as the present.

Peas and Spinach.—In localities where the land is unsuitable for sowing Peas early, and where, as suggested a few weeks back, they have been sown in strips of turf, pots, or boxes, and have been placed under a sheltered wall to harden, they should at once be planted, being careful not to break the shoots or the roots; in placing them in rows, if the ground be more than ordinarily wet, it will be well to plant them on the top of slight ridges, in all cases drawing the soil well up to the stems. As a protection from frost or winds put some small sticks to them, with a few branches of Spruce, Fir, Yew, Laurel, or any other available evergreens; failing these, some light boards, a foot high, reared up on each side and secured with a few pegs, will be found a great assistance. If in a neighbourhood where sparrows abound, at the time of planting-out attach to the sticks along the rows some white thread loose enough to wave in the wind. In some places these little marauders never touch the young tops of Peas, but, where they attack them, if some device of the above description be not adopted to scare them, they will frequently spoil a whole crop in a day or two, for, when the points of the young shoots are picked off, they seldom arrive at perfection afterwards. In planting-out Peas leave the rows sufficiently far apart (for dwarf early kinds $3\frac{1}{2}$ ft. will suffice) to admit of a row of early Spinach between, which soon immediately the Peas are planted. Peas sown in the open ground should, as soon as they are up, have a little earth drawn to their stems and be protected from birds by threads as before mentioned. Directly this is done put into the ground the requisite number of Pea-sticks, which will not only give shelter and thus admit the growth of the young plants, but will also prevent the necessity of treading over the ground between the rows afterwards, which should be sown with Spinach in the usual manner.

Cauliflower and Lettuce.—Remove at once Cauliflower and Lettuce plants from frames, hand-lights, or where they have been grown under shelter. From frames it will be necessary to transplant all the Cauliflowers; out of the plants under hand-lights allow three to remain under each light, and they will be ready in a fortnight or three weeks before those that have been moved. Elevate the hand-lights on half bricks as the plants increase in size, lifting them off every day, which will prevent their buttoning, that is, forming small useless heads prematurely. The situation selected for these Cauliflowers should be open and plentifully manured, planting them 18 in. apart in the row, and 2 ft. between. When the soil is very wet, as it is in most places at present, much injury is done by continually walking over it. This can be obviated by procuring boards of sufficient length to reach across the space to be planted, at the same time answering the purpose of a line. A small handful of the soot and lime mixture that has been before recommended for all the Cabbage family at the time of planting, will not only act as a preventive to clubbing, to which most of the family are so subject in some grounds, but it also keeps in check slugs, and is worth all its cost as a manure. The less check these plants receive in moving the better heads they will make; consequently they should be shifted with all their roots intact, and good balls of earth. In reminding amateurs about the preservation of roots in any plants they are moving, it is somewhat difficult to convey fully what is meant; it is not alone the strong roots that should receive no injury—these do not usually suffer unless subjected to the roughest treatment—it is the small delicate fibres that are so easily broken, and which are the principal agents in sustaining the plants. For a few days after planting, or whilst there is any appearance of severe weather, it is a good plan to have at hand an 8-in. or 9-in. flower-pot to shade each plant from the sun or cover up during the night as occasion may require. Some of the earliest sorts of Lettuce should also be planted out from frames and from south walls, leaving one plant to each foot of ground; those that remain near the wall will come in a fortnight earlier than the transplanted ones. For Lettuces the ground can scarcely be made too rich, as the stronger they are grown the more crisp and tender will they be, likewise standing longer before running to seed. A dressing of soot and lime round the stems of both such as are transplanted and those that remain near the wall, will much assist

them, as slugs generally take up their quarters under the shelter of such places.

Turnips.—These are often recommended to be sown so early that there is every probability of their running to seed before they have attained a size fit for use, but a little seed may now be put in. The White Dutch variety I have always found most disposed to run early to seed, but the Red American Stone will grow to a handsome size. I have for many years used no other kind; it is perfectly white inside and of excellent quality. The soil on which the early sowing is made should be rich to insure quickly-grown tender roots.

Leeks should now be sown; 3 or 4 square yards of ground will be sufficient, scattering the seeds similarly to Onions, either broadcast, or, still better, in rows, as they can be transplanted to prepared trenches when large enough. Many amateurs, who do not like the flavour of cooked Onions, are apt to suppose Leeks equally objectionable, but when thoroughly well grown and free from the disagreeable stringy character belonging to the puny, crowded plants grown on poor ground, they are so mild as to lose all the strong distasteful flavour.

Brussels Sprouts.—Of these a little seed should now be sown in a warm situation, to get them up soon. To grow this invaluable winter vegetable well a long season is required in order to give the plants time to attain their full size, in which case the produce will be above double that from the small ill-managed crops too generally met with when grown amongst other things, or alternately with Potatoes, as, on account of insufficient space, both Potatoes and Brussels Sprouts yield equally unsatisfactory results. It is far preferable to plant the Sprouts by themselves.

Peaches and Apricots.—Care must be taken that the protecting material that is over Apricot and Peach trees does not chafe the flowers and young leaves as these latter make their appearance, or it will do as much harm as good. Whatever material is employed should be so secured as not to touch them. Where branches of evergreens have been used as a shelter, they should be examined from time to time, to see that they are secure, as if the wind can easily move them, they will effect a similar injury.

Procure and sharpen ready for use the requisite quantity of Pea-sticks, sorting them into different sizes. Peas do not cling so well to old as to new sticks, but the best of those remaining from last year may be used mixed with new ones. Where any land that has been dug is of a very retentive nature, it is necessary to stir it again, as the incessant rains have made the soil in some places as sodden as if it had never been touched. A fork will be the best implement for the purpose, but in all cases it is advisable to wait until the principal portion of the superabundant moisture has had time to drain off, or the ill effects will be visible all the season. The unusually protracted winter has caused unavoidable delay in planting and sowing many things, and those who have put seeds indiscriminately into the ground will do well to examine the condition of such as have not vegetated, for any plant that has remained long in the saturated soil will be liable to rot, especially if the ground has been much trampled upon during the time of sowing.

Greenhouse Plants.

The season has arrived for re-potting many of the greenhouse plants, and a general survey of the collection should now be made for the purpose of picking out such as appear pot-bound or are likely to be benefited by being shifted into fresh soil. The process of re-potting ought to be carried out at no one time collectively, as it is always best to defer the operation to suit the nature of the different plants, and to take them in detail as growth is commencing. To do this it is requisite to make the necessary preparations, first of all obtaining pots of various sizes, which should be scrupulously clean, both inside and out, as it is of the utmost importance to the health of the plants that these should be pruned and open. Any that have been in use before should be soaked in water and well scrubbed, so as to remove any particle of dirt or slimy matter that may have collected and dried on them, in which state they become almost impervious to air, and consequently, unsuitable to the well-being of the roots of the plants that are grown in them. Before making use of the pots see that they are thoroughly dry, or the soil will adhere to the inside, and thus defeat the object sought to be obtained by scrubbing and cleansing them. Drainage is the next important matter, and here again it is imperative to observe cleanliness. If old crocks be used, they should be thoroughly sifted so as to remove all earthy matter and rubbish from among them before placing them in the pots. Those which are intended to be used for Epacris, Heaths, and other hard-wooded plants should be placed in a tub of water, and stirred round with a Birch-broom, but this only becomes necessary when they have been left out-of-doors, and have soil adhering to them. If this be done, they must be laid

out to dry before placing them in the pots. See that the latter are well drained, but in no case to excess, as the quantity of soil for the plant to grow in would by that means be considerably lessened, besides drying the ball much too quickly, thus increasing the necessity for more frequent watering, and consequently extra labour. An inch in depth is quite sufficient for a moderato-sized pot if the crocks be broken fine, and the soil prevented from running amongst them and blocking the interstices by scattering a little old Moss or Sphagnum lightly over them, placing over this a small portion of rough soil. Both this and any other used for the potting should be in a dry state, so as to admit of its being well pressed, or rammed into the pots, as occasion requires, to suit the different subjects to be treated. If the soil be too wet it binds much too closely together, and soon becomes water-logged, or otherwise in an unsuitable condition for the roots to penetrate in the requisite free manner. It used at one time to be the practice among cultivators to sift the soil for potting purposes, but this does not prevail now to any extent; and it is a matter of surprise that it ever came in vogue at all, or that it should continue, as it is detrimental in the extreme to the free growth of most plants. Before potting, see that the balls of the plants are in a healthy state as to moisture. If the soil at any time appear sour from over-watering, remove as much of it as can be done without injury to the main roots, and only give a very small shift, to be removed into a size larger later on in the season. Any that appear light in weight for the size of the pot they are in, or show from general appearances that they are likely to be dry in the middle of the ball, should be thoroughly soaked by immersing the pots in water, in which they should remain for several hours, to ensure the water penetrating and wetting the whole of the soil; for if this be not attended to before they are shifted, it is almost impossible to moisten them properly afterwards, on account of the rapid percolation of the water through the fresh soil surrounding the ball. It is a good plan to pierce the latter in several places, using for the purpose a sharp iron rod about the size of a cedar pencil. This should always be done when the balls are hard and root-bound, as is generally the case with such plants as Heaths, Epacris, and Azaleas, when they require potting. In re-potting any of the above, confine them to as small a pot as possible, avoiding any cavities between the ball and the pot. To obviate this use the potting-stick freely, ramming the soil well; with the above subjects this can scarcely be overdone, provided it is in a proper condition as to moisture, which as before observed, should be rather dry than otherwise. Epacris and Heaths of the *hymalis* type should have their branches pegged out and regulated, so as to equalise the young growth as much as possible. Place them in positions where they can have a little shade during bright sunshine, and be otherwise well attended to by way of syringing, which should be done at least once a day whenever the external air is at all dry. A pit or small close house will be found the most suitable place for them during the time they are making their growth, or, if they are to remain with the general collection, they should be placed in as favourable a position as possible to receive the requisite treatment.

Azaleas that have been forced and are now making their growth should be placed where other plants will not obstruct the light and air from their bases, otherwise the young shoots now forming will lack the necessary strength to bloom freely. Syringe them well overhead, and close the house early, so as to shut in as much of the sun-heat as possible. This will assist in making a vigorous growth, and help to keep them clear of their great enemy the thrip, that is sure to attack them if the atmosphere in which they are growing be allowed to become dry. See that they do not suffer for want of water at the roots, as that would have a like effect, and is a frequent cause of plants becoming infested either with these or other insects. Azaleas at this season require a copious supply of water, and should not for some time to come be permitted to get really dry at the roots. This applies equally to those now making their wood, as well as to others that are swelling their flower-buds, the latter of which may be occasionally assisted by an application of very weak manure-water, in cases where the plants are cramped for root-room, and likely to carry a large head of bloom. The old *A. amensis* is still one of the most useful for forcing purposes, and where an early display of these much valued plants is desired, a good stock of this kind should be kept up.

Japan Lilies.—Any of these that have been wintered in sheds, under greenhouse stages, or other out-of-the-way places, will now require immediate attention, as the young growth will soon be protruding through the soil, and, therefore, if allowed to remain long in their present position, far from the light, the shoots will become bleached and drawn. A cold damp pit or frame will be found the best place for them at this stage of their growth, and also till the young shoots require more head-room, as there they can always be kept near the glass well up to the light and have what air they

require. When treated as ordinary greenhouse plants on stages amongst others they generally become drawn and weak in the stem on account of being too far from the sun and air while making their usual rapid growth at the first start. After they are fairly through the soil give a good soaking of water if they appear at all dry at the roots, not repeating the dose till they really require it. When growth becomes more active and the pots begin to fill with roots, a greater supply of moisture will become necessary; but at this early stage the soil should only be kept slightly moist, and the longer this can be done without applying water so much the more likely are the bulbs to remain in a sound healthy state. A damp pit or frame having coal ashes or other similar material for the plants to stand on, favours a condition of this kind much better than the stage of a plant house; and in the former position plunging may be resorted to with great advantage in cultivating plants of the above character, using for the purpose half-decayed leaves or anything partaking of that nature. Japan Lilies do not readily admit of forcing, but where an early bloom is desired, a few may be placed in a warmer situation than the others, so as to bring them gently on and thus prolong the season of flowering. Choose a light airy position for this purpose, and keep them well up to the glass while the stems are soft and growth rapid, otherwise they soon become drawn. Where the re-potting of any of these has been delayed from any cause, there will now be great risk in interfering with the roots, as they are easily damaged on account of their fleshy brittle nature. The best way will be to leave the bottom portion of the ball undisturbed, and to remove as much of the top soil as can be done without injuring the bulb or breaking any roots immediately surrounding it; this can then be replaced with good rough lumps of loam and fibry peat in about equal proportions. In this the roots that are always emitted round the stem will work freely, and the plants be little the worse for not being entirely re-potted.

Statice.—These are generally treated as ordinary greenhouse plants, but to do them well they require a somewhat warmer temperature than is generally afforded to the usual occupants of the above structure. *Statice profusa*, as its name implies, is a very free blooming variety, and deserves a place in every garden. Most of the tender varieties are slow propagators, and on that account are seldom seen, except in places where large collections of plants are kept up. Although they take time, they are not at all difficult to root if the young stems be bound up in Moss or Sphagnum, containing a little peat soil and sand, forming a rough ball about 3 in. through, which must be properly supported by tying each separately to a stake, to prevent the weight of the soil and Moss weighing them down from their proper position. When bound up and supported as above, they should be placed where they can have a gentle heat, such as ainery, Peach-house, or any place of that kind affords, and where they can enjoy a natural shade, and a regular, moist atmosphere, keep them well syringed overhead, that the Moss soil may be maintained in a constantly moist state, so as to encourage the formation of roots, which the stems under these conditions soon begin to emit. The quantity of plants that may be obtained in this way is only limited to the number of young shoots available to be treated as above, for, if well attended to by way of syringing, every one is sure to form roots. When they have done this in sufficient quantity to render it safe to sever them from the parent plant, they should be cut off and potted with the Moss and soil adhering, without disturbing them in any way; if then placed in a close atmosphere for a short time they become quickly established, and soon form serviceable plants. *S. Halfordi* is likewise a very desirable variety, having much larger leaves and flowers, and altogether a more robust habit of growth. Both are valuable summer-blooming plants that last long in condition, and are well adapted for conservatory decoration. The large leaves of *S. Halfordi* soon become disfigured by thrip, an insect it is very subject to; these must be kept down by fumigation of Tobacco-paper, but the smoking should take place before any young growth commences, or the tender leaves would most likely become disfigured. A careful sponging with clear Tobacco-water will likewise remove them and any eggs that may have been deposited. *Statice* delight in a loose soil, as they require plenty of water while growing and blooming; peat and loam form a suitable mixture, or leaf-soil and the latter in the proportion of two-thirds of loam to one of either of the vegetable soils, to which should be added sufficient sand to keep the whole free and open.

Lapageria are undoubtedly the handsomest of all greenhouse climbers, and well adapted for damp shady positions that would be found unsuitable for most other plants. These delight in rough well-drained soil, with an almost unlimited supply of water while making their growth; as this is now taking place, they should at once receive a good soaking, and, if in a position where it can be

done, they ought to be syringed overhead at least once a day, and this will check both thrip and scale, to which they are subject. Cut away all shoots that have borne flowers, to make room for others just forming. Watch closely and protect any young growth protruding through the soil, as slugs are sure to seize upon the dainty morsel. Any strong shoots of these may now be layered where an increase is desired.

Stigmaphyllon ciliatum is a plant one seldom sees in greenhouses, but it is nevertheless of great value, on account of its rich canary-coloured flowers and their Orchid-like appearance, closely resembling those of an *Oncidium*. It makes a capital pillar plant, or does equally well for furnishing a trellis on walls, or any similar position. A peaty soil suits it best, and, as it is rather tender, it should have the warmest place assigned it. The forcing houses will now afford a plentiful supply of choice flowering plants to keep conservatories constantly gay, and, therefore, any that are fading should at once be removed to make room for others just coming in, that the house may be made as attractive as possible. Remove decaying blooms as they occur, that an appearance of freshness may be constantly kept up, and alter the position of plants by an occasional re-arrangement, as when seen in the same positions for any length of time they lose a portion of their interest. A few ornamental foliage plants, if judiciously placed among those in bloom, add much to their effect, and are generally more pleasing than large masses of gaudy colours alone.—J. SHEPPARD, *Woolverstone Park*.

Indoor Fruit Department.

Vines.—Muscats started as previously recommended in the early part of last month, will be pushing young wood rapidly, and at this particular stage of growth will be greatly benefited by a liberal application of tepid guano-water, which will greatly assist the bunches in acquiring their proper length. Disbud as soon as the strongest shoot is perceptible, and retain only the best bunch on each shoot until the setting process is over, when the bunches should be reduced to the number intended to ripen. Maintain a high but an agreeable temperature. As a rule we stop off heat by shutting the valves as darkness sets in, and in ordinary weather we seldom find the houses below 60° in the morning, a temperature in which the Vines luxuriate. Where early Grapes are to be gathered from pot Vines, in some cases they will be colouring. As regards watering, look to them carefully, but after this stage avoid the use of manure-water. Permit a freer circulation of air, and withhold the syringe by degrees. If red spider make its appearance, revert to hand sponging as the quickest and most effectual mode of exterminating it. In succession houses, where Vines are in good condition, and have pushed sufficiently to require tying in, that operation will require to be carefully done and by degrees. Grapes in bottles should be examined often, in order to remove faulty berries. Where they still hang on the Vines remove them at once, and well dress with syptic; otherwise they will bleed. All late Vines should now be started, that is, such as Lady Downes, Alicante, Gross Colman, and other late keeping varieties.—J. HUNTER, *Lambton Castle*.

Pot Roses.

These should now all be carefully staked and removed to a cooler house, so as to prolong their season of flowering. If grown purposely for cut bloom the buds should be carefully tied as soon as they are half open, and shaded with paper during the sunny part of day; if allowed to open fully, they soon drop after being cut. As soon as the buds commence to burst, take a piece of soft matting and tie it loosely round them—an operation which keeps the flowers in shape on the plants for one, and often two days, longer than if they were allowed to open. Forced Roses require great attention at this season as regards shading and unshading, so as to give the foliage light. Air should be given on all favourable occasions, using the syringe sparingly overhead, but keeping the house moist by damping down the paths and stages occasionally. A piece of paper is the best shade for plants in flower during the sunny part of the day, if the house is not required to be shaded all over. Finish pruning all pot Roses this month, and confine to place fresh plants under glass every week, in order to keep up a good succession till Roses come in out-of-doors. Look over all plants for the Rose maggot every morning, for if not watched one maggot will destroy all the flowers on a small plant in the space of two or three days. Alternations of heat and cold often bring on mildew, and it must be carefully watched and checked by dustings of sulphur, for, when it once gets established in a Rose-house there is no stopping it during that season's forcing, and the foliage gets destroyed. Prune all pot Roses that have not yet had that attention, and, if required, clean and top-dress the plants, and place them under glass in cold pits or in a cool-house. If required for very late flowering in pots, place them in a pit with a north aspect, so as to keep them

cooler than they otherwise would be. Water them occasionally, but sparingly, so as not to encourage growth too much, and, under such treatment Roses may be kept until late in June.—H. G.

Kitchen Garden.

Rain, snow-storms, and squally winds have been frequent in this district since my last communication, consequently work has been nearly at a standstill, and now, however fine the weather may be, it will be a hard matter to keep pace with the work requiring to be done. When the weather is unfit for outdoor operations, much may be done to advance the work in fine weather, by pointing and preparing rods, Pea-sticks, and labels; also looking over root stores, preparing seed Potatoes, &c.; all of which take up valuable time in fine weather. Walks also can be put in good order, and edgings repaired; if the walks be mossy or green, turn the gravel, and put a little fresh on the surface, well rolling it while damp, as when dry it does not bind so well. If salt be used to keep down weeds, it must be applied carefully, as it will kill Box or other growing edgings if it comes in contact with them. It is now time that all the principal seed crops were sown, Carrots and Beet—excepted, both of which, if sown too early, are liable to run to seed—the first or second week in April is sufficiently early to sow them, and, if possible, both should be grown on land that was well manured last year, or, if manured now, the ground should be deeply trenched, and the manure put at the bottom. Sow in drills, 15 in. apart. We generally have a small piece, with alternate rows of Beet and Carrots, thus combining the useful and the ornamental. Dell's Crimson Beet and Parsley alternated are also very effective. If the ground be ready, Asparagus may now be planted. Dig out a trench, a spade in width and depth, level the bottom, and on this place two-year-old seedlings at a distance of 18 in. in the row, and 2 ft. from row to row, filling in with the soil from the next trench, and so on to the end. This mode is far preferable to the beds usually raised so high above the ground-line, in which many roots perish through exposure, and in a dry season do not derive any benefit from the small amount of rain that may fall. With a fork lightly loosen the surface of established plantations, and give them a sprinkling of salt or guano, which will be all the dressing required till the autumn. Seeds of Asparagus may also now be put in; sow rather thickly to insure a crop, and thin out to 6 in. apart when 3 or 4 in. high. If not already done, plant out Shallots, Garlic, and autumn-sown Onions, also Lettuces, Cauliflowers, and Coleworts. Thin out finally the Cauliflower plants under hand-lights, and earth up those remaining; the lights should now remain quite off, unless there are indications of frost. Chicory, Salsafy, and Scorzoneria, where in request, may now be sown—the former is much in request in some places blanched for salads, and the others frequently serve as second course vegetables, when other kinds are scarce; all may be sown in drills 1 ft. asunder, and require deep, moderately rich soil. Sow a good breadth of Turnips; a cool, moist situation should be chosen for them, and, as soon as up, dust them over with wood ashes or soot, as a preventive of the fly. Radishes should be sown in quantity, according to demand, fortnightly, and will require protection from birds, either by netting or sowing with the seeds a dusting of red lead; this latter is an invaluable deterrent. Another sowing of Cauliflower and Early and Mid-summer Broccoli should now be made, and those previously sown be pricked out and grown on without hindrance of any kind, and the same remark will apply to Celery, the trenches for which, if the ground be vacant, may now be dug. Usually we grow this crop in double lines, the trenches being 2 ft. wide and 4 ft. between the trenches, on the ridges of which Lettuce and Radishes are grown and gathered before the soil is required for earthing the Celery. Should warm weather set in, the earliest Potatoes will soon be through the ground; they must therefore be watched, and the soil drawn over them in anticipation of frost. Plant main crops as soon as the soil is in a suitable condition; meantime let the seed be spread out thinly to sprout.

Forcing Vegetables.—If hot-beds be ready for Cucumbers, the plants may be at once put out, or the seeds may be sown in the hills. Till the rank gases engendered by the heating of the litter have passed away, air must be freely given. Ridge Cucumbers and Vegetable Marrows may now be sown and raised in such frames. Earth up Potatoes in frames, and as the crop is dug, utilise the space for pricking out Cauliflower and Lettuce, or for sowing French Beans, Radishes, Mustard, Cress, Basil, &c. Cover over Rhubarb and Seakale as suggested last week, and, perhaps, as the season is so late, it will be advisable to introduce another batch of Asparagus roots into the forcing pits. Tomatoes that are intended to be fruited in pots should never be allowed to get pot-bound till they are in their fruiting-pots. If wanted in fruit early, let them get pot-bound; pinch out the leading shoots, and the side laterals will soon break into flower.—W. WILDSMITH.

THE FRUIT GARDEN.

POT VINES IN SMALL GARDENS.

In many gardens with only a small glasshouse attached to the dwelling, there is seldom sufficient room to plant out Vines to any great extent, and as the holders of these often desire a few Grapes of their own cultivation, the best, easiest, and most profitable way is to grow the Vines in pots. In miscellaneous plant-houses it is difficult to rear the young Vines into a fruit-bearing state; therefore, it is generally advisable to procure ready-grown fruiting canes from some respectable nurseryman, the outlay in this way being a small consideration if future returns be taken at all into account. The principal thing to bear in mind in choosing Vines is to select varieties which are easily managed. The varieties of Black Hamburg are the safest to deal with amongst the dark fruiting kinds; white fruiting sorts may consist of Royal Muscadine, Foster's Seedling, Buckland's Sweetwater, the Duke of Buccleuch, and the Duchess of Buccleuch. The latter is small in berry compared with that of the Duke of Buccleuch, but for producing quantities of bunches there is no Grape can excel the Duchess of Buccleuch, an important advantage to those with inadequate space for the cultivation of Grapes. Before planting the Vines in their selected positions, wash every inch of the canes with soft soap and water, using a hard brush. When the roots are close to the surface do not disturb them, but remove any loose soil and replace it with a layer of moderately fresh cow manure; they are then ready for starting into growth, and should be arranged where they can receive as much sunlight and heat as possible, which are mostly to be obtained at the extreme end of the house, and sometimes against the wall of the dwelling; and as Vines do not spoil either the growth or appearance of other climbers, a cane may often be trained with advantage into any spare corner. About the beginning of April is quite early enough to start the Vines into growth; little or no fire-heat is necessary at this time, and they have the whole summer before them in which to swell and ripen their fruit. Plenty of sun-heat and abundance of light are of great assistance to the inexperienced Grape-grower. To do justice to the other inmates the Vines cannot be started quickly at first; and this is a decided advantage, as, when growth takes place in moderation, it is not so liable to become weak, straggling, and unfruitful. In fine weather the temperature should be about 55° at night; and, in colder weather, it may be 10° lower without affecting the Vines; but there is one course which must be avoided as much as possible, and that is to keep them very close and warm for a week or two, and then expose them suddenly to a much colder atmosphere. The side-shoots must have some support as soon as they are 6 in. long, and do not tie them too firmly. Pinch or stop each shoot one or two leaves beyond the bunch; and there should not be allowed to remain on each Vine more than six bunches. Do not cut any off until it can be distinctly seen which are the best formed; and thin the berries as soon as they are well established. Too many should not be cut out at first, but, at the same time, see that one berry does not interfere with the swelling of the other; in most cases at least one-half is not too many to take out. After this, give a little manure-water three times a week until the fruit begins to ripen, when nothing but clean water should be used. Guano, in a liquid state, is the best kind of manure which can be used, and it has no offensive smell. At no time must pot Vines be allowed to want-water; and, when the fruit is colouring, a free circulation of air should pass around them; but in the summer time Grapes swell and ripen well in pots with the same treatment in the way of air and heat as conservatory flowering plants, and in this way summer Grapes might be grown in every small conservatory in the country. When the Vines have produced one crop, it is very seldom they are worth fruiting again in the same pots. M.

Fruit Prospects.—These are again very promising in this district, stone fruits generally showing fine buds. Apricots were in bloom by the 1st of this month, and are now setting well with a slight protection; Peaches and Nectarines just coming into a fine

healthy bloom; Plums generally well set with buds, both on standards and walls; Apples and Pears promise well, except where exhausted by excessive crops last season. The present cold weather is of great benefit in retarding bloom, which would otherwise have been premature, and, as a natural consequence, more liable to injury from any spring frosts that might ensue.—W. Cox, *Madresfield*.

RIPENING OF LATE PEARS.

Mr. GILBERT (page 236) asks for the opinion of midland and northern district fruit-growers on late Pears. With a good collection of Pears for many years, 200 miles north of London, Baurré Rance and Bergamotte Espéren used always to ripen fairly, except after very wet, sunless summers, but if allowed to remain exposed to the air of the fruit-room, shrivelled a good deal. Ne Plus Meuris, Easter Beurré, unless after hot summers, used to ripen indifferently, until by accident I hit upon a plan that much improved them. At that time I wintered a number of my best Pears in broad, shallow boxes about 9 in. deep, as well as in ordinary drawers. One autumn, soon after the Pears were gathered, a quantity of old Peach wall blinds were heedlessly piled several feet deep upon one of the boxes filled with Easter Beurrés, and so close as to exclude the air. The box and its contents were lost sight of until the middle of February, when the Pears were found quite plump, whereas those in the drawers and other boxes were much shrivelled, and did not ripen well even when put in a warm place; and those that had been covered by the blinds having lost very little by evaporation, ripened readily in a little warmth. From that time forward I always kept these late Pears closely covered up until near the time of their being wanted, with the best results. At that distance northward, in ordinary seasons, these varieties of Pears used to be in about a similar condition at the time of gathering to what they are in the neighbourhood of London on a wet season, but even here Easter Beurré does not always ripen freely if allowed to shrivel much early in the winter. It is evident that the loss of moisture, which precedes shrivelling, prevents their ripening as they ought. A thoroughly good fruit-room, neither too damp nor too dry (a convenience not by any means so common as it ought to be), has a great deal to do with the ripening and flavour of both late Apples and Pears. T. BAINES.

A New Ladder for Fruit Gathering.—The members of the Missouri State Horticultural Society, after having carefully examined the Wright Self-adjusting Step-ladder, state that they hail with pleasure the introduction at last of an implement so long needed, viz., a step-ladder suitable for the use of fruit-growers. The Wright ladder in this respect is perfect, being strong, durable, light, and cheap, besides possessing the important and novel feature of instantly adjusting itself so as to stand firmly and level on any uneven ground or hill side, a feature of the most decided merit, and one not found in any other ladder. The above statements were heartily approved and unanimously adopted by the Society, and the president and secretary were authorized to affix their signatures thereto, as expressive of the opinion of the members in regard to it. Such a ladder is much wanted in England, and we trust it may soon be introduced.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Strawberry La Grosse Sucree.—This is an early variety not yet in general cultivation; it ripens from seven to ten days earlier than Keen's Seedling in the open air, and forces well. I have this day (March 16) picked a good dish from plants started the first week of January last.—W. Cox, *Madresfield*.

Uprire Wood v. Fertility.—In all cases it may be set down as a fact that uprيره wood is useless for fruit-bearing, or for forming fertile wood. It is dangerously deceptive as far as inexperienced pruners are concerned, as it is furnished with promising wood-buds, and many are thereby induced to rely on them, more especially in the case of Peach and Nectarine trees on open walls, and thereby lay the foundation of future failure.—JAMES GROOM, *Henham*.

Black Prince Pine-apple.—As a winter-fruiting Pine this is scarcely so well known as its merits deserve. We have from December to the present time cut a number ranging from 5 lbs. to 7½ lbs. The fruit is well grown, and is very handsome for the table, and when cut is very clean in the centre; its flavour is quite equal to that of any other winter variety.—W. Cox, *Madresfield*.

Fruit Trees on Gable Ends and Cottage Walls.—All who can would do well to help and encourage the planting of good fruit trees in these positions. I observe that the practice is pretty general in parts of Cheshire. It is desirable not only from the profit of the fruit, but also because the blossoming trees are even more effective than the early border flowers in beautifying the cottage garden in spring.—B.

Tomato Leaves and Aphides.—Everyone who trains his Tomato plants knows that his hands become covered with a strong-smelling exudation from the leaves. A French horticulturist, M. Sisroy, discovered by accident that this is poisonous to aphides, and that water in which Tomato leaves had been macerated, was quite as effective in destroying them as tobacco-water. In our climate, Tomatoes require very severe cutting away of the rich foliage to encourage the ripening of the fruit; therefore this experiment can easily be tried.—V.

A GRACEFUL AROID.

(ARISÆMA PRÆCOX.)

THE annexed illustration represents one of a curious section of Aroids, namely an *Arisæma*, many species of which well deserve culture as decorative plants, for, like Pitcher Plants and Huntsman's Cups, they are so distinct in habit, and their spathes are so singular, that they never fail to attract attention from those who pass by the more common stove and greenhouse plants. Many of the *Arisæmas* are admirably suited for pot culture in warm greenhouses or in plant stoves, and the present species, together with *A. triloba*, is one of the best. Its leaves are ternate or three-lobed, the lobes being broadly ovate and drawn out at the point into long tails, while the margins of the bright green leaflets are wavy or sinuose; the spathes are elongated, of a dull greyish-white colour striped with green, the incurved margin of the mouth being dark brown. In general appearance, indeed, they remind one of the curled or hood-like pitchers of the *Darlingtonia*. A good idea of the general appearance of plants of this kind may be gleaned from the accompanying woodcut. Like most other Aroids they luxuriate best in a rich open compost, and require a copious supply of water when making their growth. After the leaves die off, which they do after the spathes have withered, the pots in which they are growing may be packed away, like those in which *Gloxinias* are kept, until required for starting in the ensuing winter and spring. This plant has long been grown in Continental gardens under the name of *A. ringens*. B.

Spanish poor themselves say, has placed the remedy beside the disease to which it is the antidote. The bitter of Quinine cures, we know, many forms of low fever; the aromatic pungency of Ginger cures colics and flatulenc. So here we have bitter for fevers and pungent herbs for colics.

Foremost among Spanish herbs comes the Yerba (or herb) called Yerba luisa. This is a garden plant, the Lemon Verbena of our gardens. Among us the lady plucks a sprig and scents her hand with it; so does the Spanish lady; but she knows well its value, and treasures and dries for winter use every leaf of it. Its value is here well known as the finest cordial and stomachic in the world. It can be taken in two ways, either made into a decoction, with hot water and sugar, and drank cold as a tonic; or, better still, with the morning and evening cup of tea, thus: Put a sprig of Lemon Verbena—say, five or six leaves—into the tea-cup and pour the tea upon it; you will never suffer from flatulenc, never be made nervous, never have cholera, diarrhœa, or loss of appetite; besides the flavour is simply delicious. No one who has once drank their Pekœ with a sprig of Lemon Verbena will ever again drink it without it. Some remedies—nay, many—are common property, common to the regular and irregular practitioner. Such are the "Flores cordiales," of which every apothecary's shop has a store. These cordial flowers consist of the Liquorice Stick, called by the poor Palo dulce, the *Y. altea*, and the leaves and the flowers of the common scented Violet. The three are dried, mixed up together, and invariably prescribed by

Spanish practitioners for ladies suffering from a slight cold or oppression on the chest. The decoction must be taken lukewarm. Such again is the Tila, or dried buds, flowers, and fruit of the Lime or Linden tree. Marvellous is the amount of this used as tea. The decoction is taken either hot or cold, and is said to be a sovereign cure for all slight affections of the nerves. Are you low-spirited, nervous, or suffering from a sudden shock or fright?—be sure any Spanish woman passing by will bring you two farthings' worth of "Tila" from the nearest chemist's shop. Children suffer much from tape-worm, called by the peasantry "solli-

Arisæma præcox.

SPANISH HERBS.

SPANIARDS are great believers—and not merely those of the lower class—in the virtues of the native herbs of their country or immediate district. The doctor's office is constantly usurped by the herbalist, a wise man or woman, who, partly from natural talent, and partly from having received oral instruction from father or mother, and partly from long exercise of the healing art, has acquired a surprising amount of herbal knowledge. The herb doctor's house, situated in some out-of-the-way and little visited bill town, is well known to all the neighbourhood. You make your visit to it, and—if it be not the herb harvest, when the doctor is out on the hills gathering in his stock of plants to dry for the winter—you will be welcomed with Spanish courtesy, and the whole house placed "at your disposition." From the ceiling hang bundles of dried or drying herbs of all sorts, sizes, and perfumes; bulbs and roots hang in festoons, reminding one of the strings of Onions in an English peasant's cottage, from beam and rafter, and around the white-washed walls. Or, if you like to see the herb doctor doing business, you will see him sitting during market hours outside the little "plaza" of his town, his dried herbs in bundles piled beside him, and the women returning from market buying at *jd.* apiece or less, one or more of these tiny bundles, asking directions as to which will suit their case or that of some one of their children, and as to how the medicine should be made, and how strong the decoction. The herbalist very often cannot read or write; his or her knowledge is confined to the one craft, like that of the old women who deal in "simples." Yet the cures wrought by these people in cases of fever, colic, rheumatism, ague, want of appetite, and the like, are very great. The distinguishing feature of the Spanish herbs and flowers and shrubs is their intensely aromatic nature with a certain amount of bitterness.

The leading diseases among the poor are colics, wind spasms, and tertian and low fevers. Here, then, we find that Nature, as the

taria," properly "tenia." Nature offers as the remedy the leaves of the common Mint (*Y. buena*), eaten raw and on an empty stomach. The barks of trees are also much used medicinally in decoctions; the bark of the wild Pomegranate as an astringent, that of the Cedar tree as a soothing drink, besides a dozen others. But more used by regular and irregular practitioners than any other plant in decoction or tea is the "Grama." This plant is the common creeping Couch Grass (*Triticum repens*). It may be taken by the patient, in cases of fever, all the day, and is cooling and refreshing. This plant is used in such quantities that carts are laden with it. Needless is it to say that it is marvellously cheap, a remedy within the reach of all. Many drink the decoction (cold and sweetened with sugar) instead of water during the summer months. Then there is wild Rosemary (*Romero macho*), which, being the common brushwood of the hills, commands no price at all; a decoction of it is used hot, to bathe limbs in cases of rheumatism; or a few drops of its essence are put into the coarse "Aguardiente" of the country to give a fine flavour; or it may be used as a wash for the hair, although a Spanish woman's halo of glory seldom needs such stimulants. There is the "Captosera," or universal specific for colic and diarrhœa; "Jolivarda" and "Brusco," Manzanilla, or wild Camomile, good for creating appetite, and curing the pains of limbs, after fevers; "Cantahueso," a sort of large Thyme, a decoction of which will staunch a flow of blood from a stab or cut, or act as a tonic on a weak stomach; bark of wild Pomegranate, as a decoction to expel tape-worm; a beautiful species of Fern, called *Falagera*, poisonous, but useful to bathe rheumatic limbs.

PUBLIC PARKS.

By FREDERICK LAW OLMSTED.

A PARK is a space of ground used for public or private recreation, differing from a garden in its spaciousness and the broad, simple, and natural character of its scenery, and from a "wood" in the more scattered arrangement of its trees and greater expanse of its glades, and consequently of its landscapes. For the sake of completeness, recreation grounds not properly called parks will be considered under the same title. The grounds of an old English country seat are usually divided into two parts, one enclosed within the other and separated from it by some form of fence. The interior part, immediately around the dwelling, is distinguished as the pleasure ground or kept ground, the outer as the park. The park is often left open to the public, and frequently the public have certain legal rights in it, especially rights of way. The use of the park as part of a private property is to put the possibilities of disagreeable neighbourhood at a distance from the house and the more domestic grounds, to supply a pleasant place of escape from the confinement and orderliness of the more artificial parts of the establishment, and for prolonged and vigorous out-of-door exercise. The kept grounds, being used incidentally to indoor occupations, are designed in close adaptation to the plan of the house, richly decorated, and often exquisitely ordered by the constant labour of gardeners. Anciently the kept grounds were designed as a part of the same general architectural plan with the house, and were enclosed and decorated with masses of foliage clipped in imitation of cut and sculptured stone. Their lofty hedges often completely intercepted the view from the house toward the park. A recognition of the fact that the parks were much more beautiful than the kept grounds when thus fashioned, led early in the sixteenth century to the art of landscape gardening. The aim of the new art was, while still keeping the park fenced off, to manage the pleasure grounds in such a way that they would provide a harmonious and appropriate foreground to landscapes extending over the park, and to make such changes in the park itself as would improve the composition of these landscapes. The scenery of the old parks often has great beauty of a special character, which is the result of the circumstances under which the more ancient and famous of them have been formed. These were originally enclosed many centuries since for keeping deer. In choosing ground for this purpose, rich land having broad stretches of greensward pasturage, with trees more sparingly distributed than usually in the forest, was to be preferred, and this character would be increased intentionally by felling a portion of the trees, and unintentionally by the browsing of the deer; water, either flowing or still, was a necessity. In process of time the proprietors of parks established residences in them, and at length the size of their trees and the beauty of their grouping came to be matters of family pride. As the old trees decayed new were planted, with the purpose of maintaining the original character, or perhaps of carrying it nearer its ideal. Properties of this class, being associated with that which was oldest and most respectable in the land, came to be eagerly sought for, and to be formed to order as nearly as possible after the older type; and they are to be seen now in England by thousands. As a general rule, each element in their scenery is simple, natural to the soil and climate, and unobtrusive; and yet the passing observer is very strongly impressed with the manner in which views are successively opened before him through the innumerable combinations into which the individually modest elements constantly re-arrange themselves; views which often possess every quality of complete and impressive landscape compositions. It is chiefly in this character that the park has the advantage for public purposes over any other type of recreation ground, whether wilder or more artificial. Other forms of natural scenery stir the observer to warmer admiration, but it is doubtful if any, and certain that none which under ordinary circumstances man can of set purpose induce Nature to supply him, are equally soothing and refreshing, equally adapted to stimulate simple, natural, and wholesome tastes and fancies, and thus to draw the mind from absorption in the interests of an intensely artificial habit of life.

The Arrangement of Public Parks.

PRIVATE and public parks differ only in the extent of their accommodations for certain purposes, and most of the public parks in Europe are old private parks adapted to public use. When this is not the case, and a park for public use has to be formed essentially from the bare ground, its value will chiefly depend on provisions that cannot be fully matured, or have their best operation for many years after their groundwork is established. For this reason the selection of a site, the design for laying out, and the system of continuous management of a public park should be determined with great caution. The aim should be to produce the park rather than the more elaborate pleasure ground or garden style of scenery, not only for the reasons above indicated, but because a ground of this character can be consistently and suitably maintained at much less cost; because, also, it will allow the necessary conveniences for the enjoyment of it by large numbers of persons to be introduced in such a way as not to be unpleasantly conspicuous or disastrously incongruous; and because it favours such a distribution of those who visit it that few shall be seen at a time, and that the ground shall not seem overcrowded. It is a common impression that the loftier and more rugged and mountain-like the site of a public ground may be, and the more wild, picturesque, and grand scenery can be imitated in its improvement, the better it will answer its purpose. A principle of art however interposes, which M. Laine, in a discussion of the unimpresiveness of certain forms of mountain scenery, explains as follows:—"A landscape, in order to be beautiful, must have all its parts stamped with a common idea and contributing to a single sensation. If it give the lie here to what is said yonder, it destroys itself, and the spectator is in the presence of nothing but a mass of senseless objects." It is extremely difficult to provide suitably extensive and varied conveniences for the public use of a piece of ground, the elements of which are strongly picturesque, without destroying much of its original character; and the result of such attempts, unless under unusually fortunate circumstances and the guidance of unusual taste and skill, with the use of large means, is sure to be confusing and ineffective. Sites of much natural grandeur or even of bold picturesqueness are, therefore, to be selected for a park only where all necessary improvements for the convenience of a great number of visitors can be so managed that they will in some way strengthen rather than weaken the prevailing character. After these and more commonly attainable, are sites, the natural character of which would usually and significantly be termed "park-like." If the ideal of the old English park scenery be kept in view, rather than either that of a more picturesque or more artificially refined and elaborately embellished kind, it will be readily seen that in the site for a public recreation ground it is desirable that views of considerable extent should be controllable within its borders, and that in order to command them it should not be necessary that views beyond its borders be opened, the elements of which cannot be controlled, and are liable, even in the distant future, to be made inharmonious with those of the park; especially so, where such elements will have town rather than rural associations. It is generally better, therefore, that the outer parts should be the higher, the central parts the more depressed; that the surface should be tame rather than rugged, gently undulating rather than hilly. Water is desirable, and it will be best situated where it can be seen from the greatest number of widely distributed points of view. Relatively to the residences of those who are expected to benefit by it, the park will be best situated where there can be but little occasion to make thoroughfares through it. Otherwise, the less the distance and the more convenient and agreeable the intermediate roads, the better. As roads which radiate from a town are usually more important to be kept open than those which cross them, and as land near a town is relatively more needed for other uses than that more distant, it is commonly better that the breadth of the site should increase with its distance from the nearest point to the town, as in Prospect Park, Brooklyn. In the improvement of the site, attractive and suitable scenery has to be formed, and unsuitable elements of existing scenery changed or obscured; and at the same time, and on the same ground, accommodations of various kinds are to be prepared

for great numbers of people, many in carriages and on horseback, many ignorant, selfish, and wilful, of perverted tastes and lawless dispositions, each one of whom must be led as far as possible to enjoy and benefit by the scenery without preventing or seriously detracting from the enjoyment of it by all others. The most essential element of park scenery is turf in broad, unbroken fields, because in this the antithesis of the confined spaces of the town is most marked. In the climate of Great Britain turf will endure, on favourable soils, twice as much foot-wear as it will in that of Paris, or northern France, or the United States; yet in the more frequented London parks it is found necessary to surround, with strong iron hurdles, the glades on which their landscape attraction is dependent. For this and other obvious reasons, a great extent of ground must be prepared expressly for the wear of feet and wheels. In the two principal recreation grounds of Paris, the woods of Boulogne and Vincennes, though both are suburban parks and not readily used by the mass of the people, the extent of such prepared by macadamizing, paving, and otherwise, is 480 acres. In the Central Park of New York it is 100 acres, and there is a constant public demand for its enlargement, which can only be met by reducing the verdant elements of landscape, and consequently the benefit to be obtained by the use of the park. In a public park for a city, therefore, the purpose of establishing such natural beauty as soil, climate, and topography would otherwise allow to be aimed at, must be greatly sacrificed under the necessity of providing accommodations for the travel and repose of many thousands of men and horses; and, on the other hand, the extent of such accommodations must be made less than would otherwise be thought desirable, in order that the special objects of the park may be secured in a suitable degree. A plan for a park is good, indifferent, or bad, mainly according to the ingenuity, tact, and taste with which these conflicting requirements are reconciled, and to the degree in which local circumstances are skillfully turned to account if they can be made favourable, or skillfully overcome if unfavourable, for this purpose. The problem is sufficiently difficult under the simplest conditions, and it is undesirable that it should be unnecessarily complicated by a requirement to provide for various purposes which have nothing in common with that of tranquillizing rest and exercise, and to which the element of landscape beauty is not essential. Soldiers, for example, drill and manoeuvre, horses race, gymnasts and ball players exercise, on a piece of flat ground surrounded by buildings as well as in the glades of a wood. It is true that, when a suburban park is very spacious relatively to the number of people resorting to it for park recreation, a limited use of the larger turf areas for athletic exercises will injure it but little; but their frequent use for such purposes, especially if large assemblages of spectators are likely to be attracted, will be destructive of the value of the ground as a park, in the specific sense of the term. It is also to be considered that the proper rules and police arrangements for a park are different from those for a parade, ball, or gymnasium ground, or for a racecourse. Hence, when the most suitable ground near a town for these purposes adjoins that which is most suitable for a park, it is yet much better that there should be a marked division between them. Public buildings can be reconciled with the purposes of a park only in a limited degree. Ground about any building designed for an important public service should be laid out with a view, first, to convenience of communication with it; secondly, to its best exhibition as a work of architectural art. The neighbouring grounds should be shaped and planted in strict subordination to these purposes, which will involve an entirely different arrangement from that which the purpose of forming a quiet rural retreat would prescribe. A similar consideration will prevent monuments and statues from being placed profusely in a park, or at all in situations where they will be obtrusive. The same cautions apply to the introduction of botanic, zoological, and other gardens. Their main object is as different from that of a park as that of a billiard room from a library. Both one and the other may serve for recreation, and there is an advantage in being able to pass from one to the other; but the kind of recreation to be gained by one is not that of the other; the appropriate furniture of the one is not that of the

other; and their perfect combination being impracticable, the two can be much better used apart, one at a time. In the larger part of the civilised world, circumstances are as unfavourable to park-like scenery as to grand scenery in the vicinity of large towns. The climate of France is nowhere as favourable to it as that of Great Britain, and even in the north it cannot be found in perfection unless on unusually suitable soil. In the south of France, in Italy, and on all the borders of the Mediterranean, in Mexico and California, and, in short, wherever a rich close perennial turf cannot be established, parks, properly so called, ought not to be attempted. In these cases, the two natural elements of scenery to be developed in a suburban public ground of great extent are forests (or "woods") and water. While trees in woods are by no means as beautiful as trees in parks, and a forest is apt to be gloomy and to produce an oppressive sense of confinement, the mystery of this confinement, so different from that of the walls of a town, makes it interesting and recreative. In the midst of well-grown woods, public accommodations, no matter how obviously artificial, nor within reasonable limits how large they may be, detract but little from the main impression, and if fairly well designed supply a grateful relief to what might otherwise be too prolonged a mass and too nearly a monotone of colour. The introduction of long strips of clear ground, even if covered with gravel or poor herbage, giving vistas through which the light may stream in visible beams, touching the walls of foliage at the side with an infinite number of lustrous flecks, produces a most agreeable impression. Bodies of water, whether formal or naturalistic in outline, in the midst of deep dark, tall "woods," are still more effective. For the same reason statues, monuments, and gardens of highly-coloured flowers may be introduced in the midst of woods to much better advantage than in parks.

City Spaces and "Parkways."

To avoid confusion, open spaces for public use in a city may be termed "places;" and broad thoroughfares planted with trees and designed with special reference to recreation as well as for common street traffic, "parkways." The value of public gardens, places, and "parkways," in distinction from parks and "woods," is dependent less on the extent of their sylvan elements than on the degree of convenience with which they may be used; those being the most valuable, other things being equal, through which the greatest number of people may be induced to pass while following their ordinary occupations and without serious hindrance or inconvenience. Hence the most important improvement made of late in the general plan of cities has been the introduction or increase in the number and breadth of parkways which, if judiciously laid out, become principal channels or trunk lines of common traffic, to which the ordinary streets serve as feeders, so that a man wishing to go a considerable distance shall find it a saving of time and trouble to take one of them on his way. In this respect Paris has taken the lead, having formed, since 1855, over 80 miles of such trunk lines of communication, from 100 to 300 ft. in width, provided with borders of trees or shrubbery, walks and drives of a special character, seats, special lighting arrangements, and other conditions more interesting and agreeable than those of common streets. The total length of boulevards and avenues lined with trees, under the direction of the municipality, within the encinte of Paris, is 120 miles. Most of the large towns of Europe are making similar improvements, and at Washington, Chicago, Cleveland, Buffalo, Syracuse, and Brooklyn excellent examples of them exist, or are in process of formation. New York, with an area of about 42 square miles, has 7 miles of planted parkways, all of which are suburban, and as yet but partly finished. Simple places, piazzas, or plazas (the two latter being equivalent terms derived from the Italian and Spanish) have the sanitary value of making a city more airy than it would be without them. If furnished with gardens, they have the additional advantage of providing refreshment to the eye through the mind. If a piece of ground of one or two acres, in the midst of a busy town be laid out and managed with a view to providing upon it the greatest practical degree of plant beauty in trees, shrubs, flowers, and turf, and on the same general principles that a private garden for the same

purpose would be, it will be of comparatively little use; for the walks will probably be indirect, the low planting of the outer parts will obscure the general view for passers-by, and there will be frequent crowding and jostling and disturbance of quiet. Neatness, and the maintenance of orderly conduct among visitors, in such a ground, becomes also exceedingly difficult. Hence, as a rule, at least in the United States, public grounds designed with this motive soon become more forlorn than open places would be. It is much better to decorate them in such a manner as will not destroy their openness or cause inconvenience to those who have occasion to cross them. For this purpose their plans should be simple and generally formal in style, their passages should be broad and direct, and they should be provided with seats in recesses or on the borders of the broader paved or gravelled spaces, leaving ample room for free movement. Their trees should be high-stemmed and umbrageous; Conifers, except in rare instances as permanent dwarfs, should be excluded, and flowers and delicate plants little if at all used except in vases and baskets, or as fringes of architectural objects. Interest will desirably centre in a fountain.

French Parks, &c.

Every considerable town in Europe now possesses grounds which are resorted to for public recreation, and most have several of different types specially prepared and kept at public expense. In France the State has long held and managed extensive "woods and forests," remnants of the original forests which covered the country in the time of Cæsar. More than twenty such are found within a distance from Paris which makes them available for a day's pleasuring by means of railway excursion trains. They vary in extent from about 1000 acres, as at St. Cloud, to 41,000 acres, as at Fontainebleau. Each of these contains a châteaun, which at some time has been a royal residence, in connection with which there is a "park" or garden of several acres, generally containing a lake, fountains, statuary, monuments, parterres, and sometimes conservatories, aviaries, or other interesting objects. More or less historical interest also attaches to each, and in some quaint old customs are maintained, by which visitors are attracted. The forest proper is wilder, and in its depths many animals are found in a state of Nature. It is however divided by a network of broad avenues crossed by first, second, and third-class roads and walks, into spaces of five to ten acres, so that in passing through it vistas open at frequent intervals on both sides and in all directions. Some of these forests are distinguished for great rocks, trees, and picturesque scenery; some contain in their depths broad meadows and savannas, others lakes or streams with cascades; all are guarded from depredations and policed by an organised body of men trained in their duties under a military discipline. Among the more noted of these suburban resorts around Paris are those of Boulogne, Vincennes, St. Cloud, Marly, St. Germain, Rambouillet, Chantilly, and Compiègne, which together contain more than 170,000 acres. The first five are within ten miles of the city, and may be reached by rail in less than half an hour. Versailles is another resort yet more famous, and in which the woods are of less importance than the palace and gardens. The woods of Boulogne and Vincennes, being nearest the city, one at its west and the other at its east side, have since 1854 been placed under the jurisdiction of the Municipality, and fitted by extensive and important improvements, the better to serve as recreation grounds for the daily use of the citizens. The wood of Boulogne contains about 2500 acres, and the fortified line of the city forms its eastern boundary. The soil is naturally gravelly and poor, the trees are generally thickly sown, spindled, and weak, and the scenery flat and uninteresting. Several departmental roads (broad, straight, paved wagon ways) pass through it. Except in the refreshing wildness of a forest, it offered as late as 1855 but little to attract a visitor. Yet because of its close vicinity to the city it was already much frequented by the Parisians, and Napoleon III. saw in the neglect to which it had been abandoned the opportunity of making one of those sensations, to the frequent succession of which he owed so much of his popularity. The coarse, silicious soil was less costly to handle than better earth; good roads could be cheaply graded in it, and the materials of a

sufficiently firm superstructure for so porous a base were to be had on the spot by simply screening its pebbles; for the same reason scarcely any artificial drainage was necessary. There were open meadows which could be extended to the banks of the Seine. The plan of improvement was adroitly adopted to turn all these advantages to account, so that in a short time, to those who kept to certain routes, the character of the wood seemed to have been completely changed. On the immediate borders of the new roads, and on the lines of certain vistas opening from them, the surface of the ground and the foliage appear varied and picturesque, and there are certain features of scenic interest, as a cascade and grotto, the rock of which was brought from the distant forest of Fontainebleau and skilfully wrought into masses with patches of concrete imitation of stone. The greater part of the old wood remained, as far as the operations of improvement are concerned, little changed and as uninteresting as a wood might be. The approach to the improved ground from the central parts of the town is first through the Champs Élysées, afterward for a distance of 1½ mile by the new avenue Bois de Boulogne (formerly de l'Impératrice). This consists of a driveway 60 ft. wide, a bridle road on one side of it 40 ft. wide, and a walk opposite of the same width, with borders of lawn-like ground on each side, the whole space being 300 ft. in width. In the original design this avenue was expected to become the fashionable promenade of Paris; but, probably because it was not in the outset sufficiently well shaded, fashion pushed further out to the road on the south bank of a new lake in the wood 1½ mile in length, where no tolerable provision had been made for it. To meet the demand, the original drive on the lake was widened to 45 ft., and a pad or bridle path introduced by its side, 40 ft. wide. Under ordinary circumstances the greater part of the visitors to the wood concentrate on these roads and the adjoining walk. There were in the whole wood of Boulogne before 1870, when a considerable space both of the old and new planting was cleared in preparation for the defence of Paris against the Germans, 1009 acres of wooded land, 674 of unshaded turf, 75 of water surface, and 286 of drives, rides, and walks (not including the race-track). The race-ground of Longchamps, which is a part of the property, contains 195 acres, the ground leased to the Acclimatation Society for a zoological garden, 50 acres, and the leased amusement garden, the Pré Catalan, in the midst of the wood, to which a charge for admission is made, 21 acres. There are 36 miles of public drive (including the old straight forest and departmental highways), 7 miles of ride, and 15 miles of walk. The larger part of the pleasure drives are 25 to 36 ft. broad, the widest 48 ft.; the rides 12 to 17 ft.; the walks 8 to 12 ft. The wood of Vincennes, similar in other respects to that of Boulogne, contained an ancient castle which was the centre of a great military establishment, and a large plain in the midst of the wood, used as a training ground. This has been maintained, but in other respects the design for improvement has been similar to that for the wood of Boulogne, the principal difference being that the accommodations and attractions for foot visitors at Vincennes are relatively more important. The extent of the ground is 2225 acres, of which about half is wooded. There is a racecourse on the plain, and a lake of 60 acres. The public ways, not including the racecourse, take up 183 acres. There are no large parks within the fortified lines of Paris, but several beautiful small parks and gardens. The extent of the public recreation grounds within the fortified lines of the city is about 250 acres. The area of suburban grounds commonly resorted to for recreation and maintained at public expense, not including those too far away for an afternoon excursion, may be estimated at 20,000 acres. The extent of pleasure drive maintained by the Municipal Government is 87 miles, being about 3 miles of roadway to each square mile of the city, or, counting the park-ways (boulevards) shaded and with asphalt driveways, over 7 miles to the square mile. New York has less than a quarter of a mile to the square mile.

London Parks and Open Spaces.

The parks and open spaces of London are very numerous, and their total extent is larger, perhaps, than that of those belonging to any other metropolis of the first magnitude.

They are very various in area, ranging from one to several hundred acres. It has been long recognised that London owes a great deal of its physical and political health to its parks and open spaces. All the year round they act as great lungs to the mighty city, while in summer, and even to a considerable extent in winter, they are the Sunday resort of the weary workers. The open spaces of London are not confined to any quarter. The East End has Victoria Park (300 acres); Finsbury Park (115 acres), too new to be so pleasant to the eye, but still rapidly becoming what it is intended to be; and the half-dozen "downs," "fields," and "commons" that go under the general name of Hackney Downs (50 acres). It has also, lying just outside its boundaries, the two forests of Epping and Hainault, and several green breadths that may be called everybody's and yet no man's land. South London has some of the finest of the parks and open spaces. To the south-east lie Woolwich Common, Greenwich Park (17½ acres), and Greenwich Common, and nearer at hand Lewisham Common, Peckham Rye, and Southwark Park (63 acres). Directly south lie Camberwell (55 acres) and various little remnants of ancient greens and commons, while the grounds of the Crystal Palace may almost be said to answer as a park for the wide districts of Sydenham, Norwood, and Penge. South-west lie Clapham Common (10 acres), Wandsworth Common (302), and Wimbledon Common (628). Tooting Beck and Tooting Graveney Commons and Battersea Park (230 acres) also belong to this district. In the north lie Hampstead Heath (240 acres), the Greenlans, the grounds of Alexandra Park (192 acres), and Primrose Hill. In the west are found Hyde Park (about 400 acres), the Green Park, St. James's Park, Regent's Park (450 acres), Kensington Gardens (290 acres), and several small "greens," such as Shepherd's Bush. All these parks, commons, and open spaces are within the actual metropolitan district. Taking in a little wider radius, the heaths, downs, parks, and greens within easy reach of London become almost innumerable. First, beginning at the south-east and sweeping round by the south, west, north, and east, we find Chiselhurst Common; a little south-west of this Hayes Common, a great resort of cockneys in summer, where any day a score of pleasure-vans may be seen; a little further to the west Addington Common, also much frequented; still further west Mitcham Common and Banstead Downs, not to speak of those of Epsom, famous for horse races, or of the score of small spaces kept "open" by the strong hand of the law and the general consent of the people. Approaching the Thames by a north-west course, we next meet with Richmond Park (2253 acres), the largest park near London except that at Windsor (3800 acres), Hampton Court Park and Bushy Park (1842), and Kew Park and Gardens (684), the finest botanic garden in England. Crossing the river, we come next upon Ealing and Acton Greens (leaving Hounslow Heath on the left as out of our radius), Wormwood Scrubbs, and numerous little greens and commons. North of Hampstead and Alexandra Park the open spaces are fewer and smaller, and owing to a more scattered population less required. North-east lie Epping and Hainault forests, mentioned before, each of them very large and full of natural beauty. Hyde Park, the most noted of the public grounds of London, takes its name from the ancient manor of Hyde, which at one time belonged to the Abbey of Westminster, became public property in 1535, was sold by order of Parliament in 1652, and again recovered to the Crown on the Restoration in 1660. It was originally of the usual character of English private parks, a broad piece of quiet pasture ground, with numerous great trees scattered over it singly and in groups and masses. In 1730-33, a body of water was introduced (the Serpentine), but with no care to give it a natural or even a graceful outline. Roads have also been formed in the park from time to time, less with a view to public pleasure-driving than for convenient passages. What is called Rotten Row (a corruption of the French *route du roi*) was originally the passage for the king and his cavalcade between Westminster and his palace of Kensington; it is a mile long and 90 ft. wide, has a surface of loose fine gravel, and is used by the public only on horseback; it is separated from the Serpentine and "Ladies' Mile," the fashionable drive of London, by a walk and strip of turf of variable width. It divides and overpowers what might otherwise be a pleasing landscape expanse, and no

attempt has been made to mitigate the harshness of the invasion. Parts of Hyde Park have lately been made into gardens, and in these during parts of the summer there is a very brilliant display of flowers and sub-tropical plants; but the old trees are disappearing more rapidly than young ones are brought forward; the turf is not well kept, and to avoid its destruction in many parts iron hurdles are placed along the walks. It is thus gradually losing its beauty as a park, for which its streaks of fine gardening here and there offer no compensation. Regent's Park, formerly part of old Marylebone Park, was laid out in 1812. There is a drive of nearly two miles around it, and within are the Botanic and Zoological Gardens, and a lake. Victoria Park in East London was opened to the public in 1845. A fine drinking fountain, 60 ft. high and costing £5000, given by Lady Burdett-Coutts, was erected in it in 1862. St. James's Park was formed and walled in by Henry VIII., was much improved under Charles II., and was arranged as it now appears chiefly under George IV. The public property in many of the larger commons of London is so complicated by ancient manorial and local rights that its extent cannot be accurately stated. The aggregate area of the several public and crown parks that have been named, together with so much of the commons lying within the metropolitan district, as is under the Board of Works, is about 13,000 acres. There is also in the squares and gardens, most of which have been established by landlords, and are private property but of great public advantage, about 1200 acres. Liverpool and its suburb Birkenhead have six parks, five of which are recent acquisitions, and yet incompletely prepared for public use. The largest, Sefton Park, contains 387 acres. Birkenhead Park contains 120 acres, besides the leased villa grounds (60 acres) by which it is surrounded. It was undertaken as a land speculation, and, though too small in scale and too garden-like for the general popular use of a large community, is very pleasing, and is one of the most instructive to study in Europe, having been laid out and the trees planted under the direction of the late Sir Jos. Paxton, more than thirty years ago. The corporation of Leeds has lately purchased a noble park of 800 acres, containing a fine stream of water and a lake, formed by the previous owner, of 33 acres. Its scenery is diversified, and it commands fine distant rural views. These advantages and its exemption from injury by factory smoke compensate for the necessity the citizens will be under of reaching it by rail, its distance from the town being four miles. Birmingham, Manchester, Bradford, and other manufacturing towns of England have acquired parks by the subscription of citizens or by joint-stock companies. At Halifax a park has been formed and given to the town by a benevolent citizen. Derby is provided in the same way with an arboretum. The city of Lincoln is forming an arboretum on land purchased for this purpose. Most of the small towns of England have some place of recreation, as for instance, the old city walls and the river banks above the town at Chester, the common and the old castle grounds at Hereford, and the cathedral greens at Salisbury and Winchester. These consist in each case either of a long broad walk, pleasantly bordered and leading to fine views, or a few acres of smooth turf with shaded borders. Most villages in England have a private park near them, which people are allowed to use. When this is not the case, even a hamlet almost invariably has at least a bit of cricket-ground or common, where, on benches under a patriarchal oak or elm, the old people meet to gossip and watch the sports of youth. Phoenix Park at Dublin (1752 acres) is a fine upland meadow, fringed and dotted with trees, but badly laid out and badly kept, being much larger than the city requires or can afford to take suitable care of.

Continental Parks and Gardens.

The old towns of the Continent have generally provided themselves with recreation-grounds by out-growing their ancient borders of wall and moat, and glacis, razing the wall, filling part of the moat, and so, with more or less skillful management of the materials, making the groundwork of a garden in the natural style. This is done admirably at Frankfort, Leipsic, and Vienna. Elsewhere simple broad walks bordered with trees have been laid out upon the levelled parts. The principal promenade of Vienna is the Prater, th

chief feature of which is a straight carriage-road over a mile long, with a walk on one side and a riding pad on the other. It contains near the town a great number of coffee-houses and playhouses; but, as it is five miles long, considerable portions are thoroughly secluded and rural. Before the recent improvements of the Bois de Boulogne, it was the most frequented large recreation-ground in the world. There are numerous other public grounds at Vienna, both urban and suburban. The English garden at Munich was laid out under the direction of Count Rumford by the Baron von Skell. It has serious defects, but its scenery in the English style has been considered more agreeable than that of any other public park on the Continent; it is about four miles long and half a mile wide. The Thiergarten at Berlin contains over 200 acres of perfectly flat land, chiefly a close wood, laid out in straight roads, walks, and riding pads; its scenery is uninteresting. The Prussian royal gardens of Sans Souci, Charlottenburg, and Heilgensee are all extensive grounds, the two former in mixed, the latter in natural style. Public grounds worthy of a traveller's attention exist at Cologne, Dresden, Düsseldorf, Stuttgart, Hanover, Brunswick, Baden, Cassel, Darmstadt, Gotha, Weimar, Würzburg, Schwetzingen, Pöplitz, Prague, and Hamburg. Coffee or beer-houses are important adjuncts of German public gardens. The refreshments furnished are plain and wholesome, and the prices moderate. Many families habitually resort to these for their evening meal, especially when, as is usually the case, there is the additional attraction of excellent music furnished by the Government. The gardens of Antwerp, the Hague, and Warsaw, and the "city grove" of Pesth, are also remarkable. The famous summer gardens of St. Petersburg are not extensive, being but half a mile long by a quarter of a mile wide, and formal in style. They contain fine trees, are rich in statuary (boxed up in winter), and are the most carefully-kept public gardens in the world, as shown in the exceeding freshness and vigour of the plants and flowers and in the deep vivid green of the turf. The more fashionable promenade of St. Petersburg is in the gardens of Katharinenhof, where, on the 1st of May, an annual procession of private carriages of almost endless length is headed by that of the Emperor. A remarkable garden is that of Tzarsoyke Selo, in which is the residence of the Imperial family, about two hours' ride from St. Petersburg. Besides the palace, it contains temples, banqueting-houses, and theatres, a complete village in the Chinese style, a Turkish mosque, a hermitage, and numerous monuments of military and other achievements. But beyond this museum of incongruous objects there is a park in which there is natural and very beautiful scenery both open and wooded, and much of it is simple. The keeping of the ground employs 600 men. Stockholm has a great variety of delightful water-side rural walks; but the chief object of pride with its people is the Djurgard or deer park, which is a large tract of undulating ground about three miles in circumference, containing grand masses of rock and some fine old trees. The Haga park, also at Stockholm, is picturesque, and has the peculiarity of natural water communications between its different parts and the city, so that it is much visited in boats. The environs of Copenhagen contain many grounds of public resort, but the notable promenade of the city is the Royal deer park (Dyrhave). In all the Italian cities the chief public rural resorts are gardens attached to the villas of ancient noble families. The Cascine of Florence is an old pasture of the dairy of the former grand dukes on the banks of the Arno, passing through which are broad straight carriage-drives. It contains little that is attractive, but commands delightful views. At a space whence several roads radiate a band of music usually performs at intervals during the promenade hours. The Municipality is now preparing promenades and recreation-grounds, which promise to be of remarkable interest. The fashionable promenade of Rome has been on the Pincian Hill, which has few attractions except in its magnificent distant views. Since Rome was made the capital of the new kingdom of Italy, large public grounds in other quarters have been projected, and in great part formed by the Municipality. At Naples the fashionable promenade is the Riviera di Chiaja, a public street. It is divided into a ride, a drive, and a walk, and is nearly a mile in length with a breadth of 200 ft. A part of it is separated from the shore of the Bay of Naples by the Villa Reale, planted in the garden

style. Most towns of Spanish or Portuguese origin are provided with a promenade of formal avenues, to which, generally at dusk, custom brings the ladies in open carriages and the gentlemen on foot or on horseback.

American Parks.

Until some years after the middle of the present century no city in North America had begun to make provision for a park. To a certain extent cemeteries were made to serve the purpose. In 1849 Mr. A. J. Downing began in the "Horticulturist" a series of papers which were widely copied, and did much to create a demand on this subject. At length a large tract of land was provided in New York, upon which in 1858 the preparation of the present central park was begun. The topography of the ground was in all important respects the reverse of that which would have been chosen with an intelligent understanding of the desiderata of a park. The difficulties presented could only have been tolerably overcome by an enormous outlay. The popularity of the parts of the park first prepared, however, was so great that the necessary means for improvements on a large scale were readily granted. The magnitude of the operations (nearly 4000 men being at one time employed on the works), the rapidity of the changes wrought, and the novelty of the scenes presented, soon gave the enterprise great celebrity; and the rapid rise in the taxable value of the land near it more than met the interest on its cost. An efficient management of its public use was maintained, and though frequented by great crowds of people it was found, contrary to general expectation, that a degree of good order and of social amenity prevailed, nowhere surpassed and rarely equalled in the public places of Europe. Philadelphia, Brooklyn, Albany, Providence, Baltimore, Buffalo, Chicago, St. Louis, Cincinnati, Montreal, and San Francisco have since each acquired land for one or more parks of considerable extent, the average being over 500 acres. As in the case of New York, the selection of ground has often been made more with reference to other considerations than to that of fitness for the intended use. Some are as yet only held for future use, while in others provisions essentially temporary and which will be in the way of substantial improvement, are made; none are so far complete and well fitted as fairly to illustrate the ends which a park should be designed to serve. The central park of New York is $2\frac{1}{2}$ miles long and half a mile wide, but this space is practically divided by the reservoirs of the city water works, which are elevated above its general level and occupy 142 acres. Deducting besides this certain other spaces occupied for special public purposes, the area of the park proper is 683 acres; of this, 55 acres are in meadow-like ground, 54 in smaller glades of turf, 400 of rocky and wooded surface, 43 in six pieces of water (the largest being 20 acres), 15 in riding ways, 52 in carriage ways, and 39 in walks. There are $5\frac{1}{2}$ miles of rides, $9\frac{1}{2}$ miles of drives, and 28 miles of walks. Omitting a few by-roads, the average breadth of the drives is 50 ft., and of the walks 13 ft. There are eight bridges (over water) and thirty-eight tunnels and subway arches, fifteen of which are concealed from view by plantations carried over them, and all of which are expedients for reconciling within narrow limits the large amount of foot, horse, and wheel room required with sylvan and pastoral landscapes. On the east side, near the middle of the parallelogram containing the park and reservoirs, ground is reserved for a great museum of art; and beyond its boundary on the west side another plot is held for a museum of natural history. The first block of each is now building. There are carriage and foot entrances at the two southern corners, and between them on the south end, at the termini of street railroads, there are two foot entrances; and fourteen other entrances are in use or provided for. From the S.E. or Fifth Avenue approach, which is most used, the visitor is led by a nearly direct course to a slightly elevated point in the interior of the park; northwardly from which, at great cost in reducing the original rocky knolls, broad green surfaces have been prepared, and views of a tranquil landscape character obtained of considerable extent. At the most distant visible point a small tower of grey stone has been built to attract the eye, and the perspective effect is aided by the character and disposition of the foliage, and especially by an avenue of Elms leading toward

it. At the end of this avenue, termed the Mall, the ground falls rapidly to the arm of a lake, and here a structure called the Terrace has been introduced, which, though mainly below the general plane of the landscape and unobtrusive, supplies a considerable shelter and place of reunion. It is designed to be richly decorated with sculptured works. On the opposite side of the water is a rocky and wooded slope threaded by numerous paths, called the Ramble. These with the green playground reserved for the scholars of the public schools, two irregular bodies of water, and several rocky knolls (on one of which is the Kinderburg, a place for little children), form the chief features of the south park. Those of the north are a central meadow divided by a rocky spur, the high wooded ground beyond it with a steep rocky face on the north, and an intermediate glen with a chain of waters. The number of visits to the park sometimes exceeds 100,000 in a day, and is about 10,000,000 a year. Prospect Park, Brooklyn, N. Y., contains, with the adjoining parade ground, 550 acres. There is included in it a considerable amount of old wood, and for this reason, and because of the better soil, climate, and early horticultural management, it has a finer rural and more mature character than the New York Park, though its construction was begun eight years later. It has about 6 miles of drives, 4 miles of ride, and 20 miles of walks. Its artificial water covers a space of 50 acres, and is supplied from a well by a steam pump. It commands a fine view over the ocean. There are thirty-three smaller public grounds in New York and Brooklyn, all but three of which are improved and in use, the total pleasure ground space of the two cities being 1600 acres. Fairmount Park, Philadelphia, is a body of land 2740 acres in extent, having a great variety of surface, all of it of considerable natural beauty. The heights command fine distant prospects; it bears many noble trees, and at the part most remote from the city there is a glen through which dashes a charmingly picturesque stream. It is divided by the Schuylkill river and crossed by a common highway, and in two directions by railroads, the cuttings and embankments of which unfortunately completely break the naturally most quiet scenes. These, with other structures, some of which have been recently erected and are designed to be permanent, greatly disturb its natural beauty. The object of the city in acquiring the ground was to control it against such occupations as would peril its water supply, and its permanent disposition is not fully determined. Appropriations have been already made for two large reservoirs, for pumping works and for a zoological garden. No measure has yet been taken looking to the permanent preservation or special preparation of any considerable part distinctly as a park; but drives, rides, and walks have been formed, mainly temporary, by which all parts are traversed or laid open to view. Several houses which were originally private villas are used as refectories; the river is well adapted to pleasure-boating; the spaces are so large that few restrictions on the movements of visitors are necessary; and in spite of the defects to which allusion has been made, the ground offers better and larger opportunities for popular rural recreation than are possessed in a single property by any other city in the world. Druid Hill Park, in Baltimore (600 acres), is a very beautiful old wood, acquired by the city in 1860, the original private improvements of which have been enlarged and extended for public use. Buffalo is forming the most complete system of recreation-grounds of any city in the United States. It will consist of an inland suburban park of 300 acres, of very quiet rural character, with an ample approach from the centre of the city, and park-ways 200 ft. wide extending from it in opposite directions, one to a promenade overlooking Lake Erie, the other to a parade-ground and a garden on the opposite side of the town. There is a fine natural growth of trees in the main park, a lake of 46 acres has been formed, and several miles of fair macadamized roads and walks constructed, together with various suitable buildings. The work was commenced in 1871, and has been advanced very steadily and economically. The aggregate area of ground occupied, including the park-ways, is 530 acres. Chicago is situated in a region most unfavourable to parks, and should she ever have any that are deserving the name, it will be because of a persistent wisdom of administration and a scientific skill as well as art in the

constant management of those which she is setting about, such as has been nowhere else applied to a similar purpose. The grounds appropriated are flat, poor in soil, and devoid of desirable natural growth, or, except two which look upon Lake Michigan, of any natural features of interest. In one it is proposed to transform a series of marshes, partly overflowed by high water of the lake, into lagoons, the quiet water-surface of which is designed to take the place ordinarily given to lawns in sylvan landscapes; this, if the idea be consistently carried out, will be unique and interesting. The Chicago Park system contains nearly 1900 acres of land, in six parks, of an average extent of 250 acres each, three in one chain, and all, with one exception, connected by park-ways. About twenty miles of park-way, from 200 to 250 ft. wide, has been laid out (in the city and suburbs), nearly half of which is already provided with good macadamized or concrete roads and well planted. St. Louis now controls 2100 acres of lands held for recreation-grounds, of which about 100 are in city grounds, the greater part improved and in use, and the remainder suitable for parks proper, the smallest field being of 180 acres, and the largest of 1350. Of the latter, one only, Tower Grove Park, containing 277 acres, is yet at all adapted to use. A park-way 120 ft. wide and 12 miles long is under construction. Cincinnati has a little over 400 acres of public recreation-ground, 207 being in Eden Park, which lies on undulating ground commanding fine distant views, and 168 in Burnett Wood, which has a similar surface with a fine growth of indigenous trees. There will be about three miles of pleasure road in each. Cincinnati possesses in Spring Grove Cemetery the best example in the world probably of landscape gardening applied to a burial place; and her parks are likely to be improved with the same taste and skill. San Francisco holds 1100 acres of land for recreation-grounds, of which over 1000 acres are in one body, called the Golden Gate Park. This borders on the ocean, and is very bleak and partly covered with drift sand; no trees grow upon it except in an extremely dwarfed and distorted form, and turf can only be maintained by profuse artificial watering; but wherever shelter, fertility, and sufficient root moisture can be secured, a low, southern, almost sub-tropical vegetation may be maintained throughout the year, of striking luxuriance and beauty. Experiments in arresting the sand and forming a screen of foliage on the shore have been made with promising success. If steadily, boldly, and generously pursued, with a cautious humouring of the design to the unique natural conditions, and skilful adaptation of available means, a pleasure-ground not at all park-like, but strikingly original and highly attractive, may be expected. Nearly seven miles of the ground have already been formed into a carriage road, which is much used. A park-way stretching three miles along the shore is provided for, the reservation for it ranging from 200 to 400 ft. in breadth.—"Appleton's Cyclopædia."

The "Picturesque and Beautiful."—In the excellent "Transactions" of the Massachusetts Horticultural Society just received, we find, among many interesting articles, a long paper on "Landscape Gardening," the effect of which is greatly marred by a discussion on the old and vain definition of the "beautiful" and the "picturesque" &c. There are certain things in books which mainly serve as a clog to progress or healthy discussion, and the feeble and incomprehensible drivel about the "picturesque," the "beautiful," and the "gardensque," is certainly as mischievous as anything we know of. The object of landscape-gardening artists or essayists is or ought to be to make our gardens beautiful, varied, and natural; and it is sad to see a number of people wasting time in defining the indefinable and separating the inseparable. Writers on this subject should go straight to the point, not dallying with terms, and tell us (if they can) how to make our gardens more natural and satisfying at all seasons—how to drive the long-lived and stupid geometry out of them, as having no more legitimate place therein than in a picture—how, in fact, to arrange the garden that it may be attractive to all men of taste or feeling, as well as to the professional horticulturist.

Royal Horticultural Society.—A circular has been forwarded to the Fellows of the Society stating that the Council, being desirous of extending a knowledge of practical horticulture, contemplate the foundation of lectures and demonstrations on the subject. Their intention is to have lectures delivered by properly-qualified instructors, in the Society's Hall, at South Kensington, and to give practical instruction in the garden at Chiswick.

NOTES OF THE WEEK.

— **CAMELLIA** COUNT NESSELEODE is in great beauty now, and serves to show the great improvements that have lately been made in different varieties of this noble plant. It has flowers of a delicate rose colour, with a distinct white line margining each petal. There is a good plant of it in the Camellia house in the Royal Exotic Nursery, Chelsea.

— **THE** new *Phalopsis Mannii* is now in flower in Mr. Heriot's collection at Cholmondeley Park, Highgate. It has yellow flowers about 2 in. in diameter, the sepals and petals being conspicuously blotched and spotted with rich brown. The lip is very singular, the lateral lobes being erect, white, streaked with purple, while the central lobe is lunate and fringed. This species is far prettier than its allies *P. fuscata* and *P. cornucervi*.

— **THE** first annual report of the Chicago Botanical Garden has been published, giving an account of the progress of this undertaking. The Garden is located in the South Park, Chicago, where 23 acres have been laid out in beds for the temporary reception of hardy plants. A plan has been prepared for the permanent arrangement of the entire ground.

— **FROM** a Parliamentary Return lately issued we glean the following details relating to the quantity of land cultivated as orchards market gardens, nurseries, and woods in Great Britain. The grand total in acres is as follows:—Orchards, 154,584; market gardens, 39,957; nursery grounds, 12,042; woods and coppices, 2,187,078.

— **A** FINE plant of the rare *Dendrobium Wardianum* is now in bloom in Messrs. Veitch's collection at Chelsea. It is one of the best coloured varieties we have yet seen, the magenta tips to the ivory-like sepals and petals, as well as the large crimson blotches of the lip, being very rich and distinct. The rare *Cattleya Veitchii* is also showing flower, and is expected to open in a few days.

— **IN** Missouri last year, after the locusts had eaten down the "Blue Grass" so closely that the greater part of it died, cultivators were agreeably surprised to find its place taken by a plentiful growth of an annual Grass (*Vilfa vaginifolia*) heretofore unknown to them. The seeds of the new Grass had been supplied by a moderate number of plants, year after year, in sufficient quantity to secure a good crop, had they not been choked and kept down by the greater vigour of other and stronger plants.

— **MOUNDS** of earth are now being raised on the south side of the Serpentine in Hyde Park. They are set up in spaces between the fine old Beech and Elm trees in such positions that, with the aid of the latter, they will, when they are planted, form a screen between the Serpentine and Rotten Row. From a landscape-gardening point of view, this is to be regretted, as the gentle slope to the water was better than the kidney-shaped mounds. These, like many others too often seen in gardens now-a-days, are not formed so as to harmonise with the surrounding ground: their slopes are too abrupt, there are no gentle gradations.

— **IN** the planting of street trees—a practice happily becoming more common—there are many mistakes being made. One of the most usual errors is planting trees too large for the positions in which they are placed. Thus, on the well-managed Pembroke property, to the south of Dublin, many Wych Elms are planted, and, though young, they are too large for the streets, and they have recently been lopped in the most barbarous and ignorant manner. It is easy to adapt the tree to the width of the thoroughfare. The common *Acacia* is a very good tree for streets that are not very wide, and there are various others, medium-sized and pyramid trees, that ought, for ordinary streets and roads, to be preferred to the giants of the forest.

— **THE** Commissioners of 1851, says the "Pall Mall Gazette," are never weary of doing kindnesses to that interesting mendicant the Royal Horticultural Society. The Council have apparently shrunk from the work of going round in person to solicit subscriptions, and a species of begging-letter has been prepared and lithographed, and entrusted for distribution to a professional canvasser. That the Council should prefer doing this unpleasant part of their business by deputy is natural enough; the curious part of the transaction is that the canvasser is a servant of the Commissioners of 1851. These tender-hearted landlords first let trust property at a nominal rent to certain residents in South Kensington, then excuse them from paying this nominal rent, and finally, when it becomes impossible to do this any longer, lend one of their clerks to their defaulting tenants to solicit aid in the neighbourhood towards making up the rent. Everybody must be pleased with this arrangement, with the exception of the pabry interests—science, art, and so forth—which used to dream that they were to be benefited by the surplus proceeds of the Exhibition of 1851.

— **A** MR. SPITZ has found in working a stone-quarry near La Prairie, in Adams Co., Ill., both stalks and ears of Indian Corn, of full size and perfect in appearance, in a petrified condition and imbedded in a stratum of sandstone, 4 ft. in thickness. This is said to be good evidence that this plant was extensively cultivated in America before the appearance of the white man.

— **THE** Strawberry Colonel Cheney is very highly spoken of in America, and is said to be good for all soils and all parts of the country. Some say it beats the long-famed Wilson, hitherto one of the best of American Strawberries.

— **LAST** year's vintage in France has now been ascertained in round numbers to have been 84,000,000 hectolitres; taken at 1s. a gallon, there is a result of astonishing millions, showing how the German demand of "money or your life" was paid off.

— **AN** Order of the American Centennial Exhibition managers fixes the date for the exhibition of various products of the garden thus:—Pomological products and vegetables, May 10; Strawberries, June 7 to 15; early summer vegetables, June 20 to 24; Raspberries, July 3 to 8; southern pomological, July 18 to 22; Melons, August 22 to 26; Peaches, September 4 to 9; northern pomological, September 11 to 16; autumn vegetables, September 19 to 23; Potatoes and feeding roots, October 2 to 7; Nuts, October 25 to November 10. These will be exhibited in a building erected for that purpose. This list comprises only the most important.

The Architectural Gateway a Mistake.—Is not this generally speaking, a pretentious mistake? not certainly in an old keep or castle, where there is a reason for its existence, and where it is part and parcel of architecture that has a use and a meaning; but the modern architectural gateway, a mile or two from the house or perhaps any other structure bigger than the lodge, and flanked by low hedges or a wooden fence is, like a boat on a highway, a little out of place. It is, in fact, one of the minor humbugs of architecture, and I should like to caution landscape gardeners against encouraging the fashion. Better, many times, use a simple railed gate.—V.

Children Poisoned by Water Hemlock.—Several children have been poisoned at Stockton-on-Tees, and two have died. It appears that a man named Kinderl found some roots which he thought were Parsnips. These he put into his pocket. By some means, not yet explained, portions of the roots were eaten by several children, who became ill, showing symptoms of poisoning. On the one hand, it is stated that the children must have taken the roots from Kinderl's pocket, while on the other it is asserted that he gave them the poisonous herb, which is said to be Water Hemlock. Kinderl is in custody.

NOTES AND QUESTIONS—VARIOUS.

Distilling the Odours of Flowers.—Will any of your readers kindly tell me through THE GARDEN, how to distil the fragrant essence of Roses, Violets, and other flowers? I should like to know if there is any machine that could be used for the purpose on a small scale.—F. W. G.

An Orchard Country.—It is estimated that within a radius of two miles at La Salle, Niagara County, N.Y., there are 52,000 fruit trees growing. Of these, 37,400 are Apple, 42,400 Peach, 1300 Quince, 3000 Pear, and 500 Crab Apple trees.

The Coca Leaf.—I should be glad if you could inform me where the leaves of the *Erythroxylon Coca* could be procured, as I wish to make some experiments with them.—EDWIN W. GERR. [Coca leaf may be obtained from Hooper & Co., 24, Russell Street, Covent Garden, W.C., at the rate of 1s. an ounce.]

The Nettle as a Vegetable.—London speaks very highly of the Nettle, either as a pot-herb for soups or for dishes like Spinach, and gives a plan for blanching it in the same manner as other plants. He says:—"We have known the Nettle forced by being planted close to the due in a vinery, so as to produce excellent Nettle-Kale and Nettle-Spinach in the last week of January."

Myosotis dissitifolia in Pots.—Owing to the tendency this plant has to acquire green-fly or to damp off, if potted early it is advisable to lift it into pots as just as the flower-buds are visible, and if then placed in a cool airy house it will be a mass of flowers. For indoor use 48-sized pots are best, but for a conservatory a fine effect is obtained from large plants in 24-sized pots.—A. D.

Frost v. Apricot Blossoms.—We have had severe weather for March. On the 19th we had 9° of frost, with snow and hail; on the 20th, 8°, and a clear day; on the 21st 8° and snow. Apricots are in full bloom; ours are protected with Frigi Domo, and are all safe; on trees not protected all expanded blossoms are destroyed.—DAVID LUXBURG, Stegford.

Cut Roses at South Kensington.—In your issue of Saturday last credit is given for the exhibition of one box of Roses to the firm of W. Paul & Son. Will you kindly correct this and oblige us.—PATRICK SON, Cheshunt.

Ben Davis Apple.—Will any of your readers kindly tell me if this Apple is cultivated in this country; and if so, what is its character?—J. W.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

BILLBERGIAS.

AMONG these South American Bromeliaceous plants, are some splendid flowering subjects, which in general habit partake somewhat of the character of the Pine-apple; and, as in the Pine, their flower-spikes, are emitted from the centre of the plants, but they differ considerably in the forms which they assume, some being quite erect—as in the case of the Thyrs-like *Billbergia* (*B. thyrsoidea*), the flowers opening almost on a level with the intense crimson bracts from which they spring, forming a dense head of splendidly-coloured inflorescence. In others, like the Morel *Billbergia* (*B. Moreliana*), the flower-spikes are loose and open in character, and droop elegantly from the centre. Others, again, like *B. polystachya* (the many-spiked *Billbergia*), have erect spikes, but somewhat branched. All the *Billbergias* are easily grown, being sufficiently similar in their requirements generally to succeed under the same treatment. After they have flowered, they throw up suckers from the base; these should not be taken off too soon, as, although they will root when removed in a small state, they nevertheless make much quicker progress upon the plant which has produced them, until they get to a moderate size, say one-fourth or fifth of that of the parent plant. When taken off at that stage they root quickly, and sustain little or no check. They will throw out roots at any time of the year, but it is generally the best to take them off early in the spring, say about the beginning of March, as in that case they have plenty of time to get established before autumn; they should be slipped off from the stools that have produced them just at the point from which they spring, and any that are near the soil will most likely have some roots attached to them, in which case they may at once be placed in pots just large enough to hold them. Others, that have not made any roots, should have a few of the bottom leaves stripped off and put in pots, one-fourth filled with drainage; the soil in which they are grown should be good turfy loam, to which as much sand has been added as will keep it porous; insert the suckers well up to the leaves, pressing the soil down firmly, and do not give any water for some days, or it will make the soil too wet; place them in a house or pit in which there is a night temperature of 60°, and 6° or 8° higher in the day; if they can be accommodated with a bottom-heat of 80° they will root quicker than they otherwise would do, but do not confine them in a propagating-frame or under glasses, as is done in the case of cuttings, for, if too humid, they are liable to rot. In the course of a month or so they will have made roots, when the temperature may be from 70° to 75° at night and 10° higher by day, air being given when required. By midsummer they should be in a fit condition for shifting into pots a size larger than those they are in, but none of the family should be over-potted, as they do not like more soil than the roots can fully occupy. Let them have a light situation, but during summer they will require a thin shade in sunny weather. Supply them regularly with water as it is required, and syringe them overhead in the afternoons during the season of active growth; continue this treatment until the beginning of September, when they will not need further shading, and syringing may also be discontinued. The temperature may now be reduced 5° day and night, and by the middle of October it may be allowed to fall to 60° at night, a point at which it may be kept throughout the winter, during which they will want less water but should never be allowed to get too dry. In spring, as the days lengthen, raise the temperature a few degrees; by the beginning of May the roots will be in an active condition, and the plants should be moved into pots a size larger than those they are in, using the soil in a similar state; if a few bits of crocks or charcoal be added it will ensure the roots keeping healthy, as they dislike anything of a sodden impervious character. As the season advances increase the temperature to the same height as it was during the previous summer, and

give air as before, shading when requisite. This season the plants will, if all goes on well, make strong growth, and some of them may need a second shift in July, *i.e.*, if the pots are well filled with roots, but, unless that is the case, do not move them. To such as evidently require more room give pots 2 in. larger than those they were in, after which encourage them to make all the growth possible by giving them plenty of heat and light, as the stronger the plants the finer will the flowers be. In autumn again reduce the temperature, and treat them through the winter as during the preceding one. They will not require re-potting in spring, but in everything else they should be managed as already recommended, and they will throw up their bloom-spikes during the spring and summer. When in flower, move them to the coolest end of the stove, or to an intermediate house, if such is available, in which a drier atmosphere is maintained. Thus situated, the flowers will last longer than they otherwise would do. After blooming, they should be kept in the stove, and treated in every way as hitherto; for upon the attention which they get will depend their ability to produce suckers quickly, and in such condition as will grow up to a flowering size in the least time. After the first suckers are removed, the old plants, if well cared for, will throw up more, which may either be taken off and rooted singly, as already described, or they may, if large specimens be wanted, be allowed to remain on the old plant. These, if shifted into larger pots, and grown on, will make flowering crowns in one season. The following are a few of the best kinds which will form an acceptable addition to any collection of stove plants, as even when not in flower, they have a distinct and handsome appearance. *B. Moreliana* is not only one of the best of *Billbergias*, but also one of the most beautiful of the whole Bromeliaceous Order; it is a native of Brazil. Its leaves, which grow to a considerable length, have a lively green ground colour, banded with white; its flower-spike being drooping and very graceful. *B. Saundersii* is a stout-growing species, with strap-shaped leaves, 10 or 12 in. in length, spined on the margin, the under surface being of a purplish colour, and covered with light-coloured blotches; the flowers are produced in half-drooping racemes about 12 in. in length, furnished with long crimson bracts; the calyx is crimson; the corolla deep blue, and the anthers orange. It has been recently introduced from Bahia. *B. thyrsoidea* has bright green leaves, with small spines on their edges, blunt at the point, and slightly reflexed; bracts, rich crimson, forming an oblong, obtuse cone; flowers, similar in colour to the bracts, close and erect. *B. polystachya* has leaves furnished with strong spines and an erect spike. The bracts are small and reddish crimson, the flowers purple. It comes from Brazil. The Iris-leaved *Billbergia*, *B. iridifolia*, is a handsome species, with blue and yellow flowers. This and the preceding come from Rio Janeiro. *Billbergias* suffer little from red spider, thrips, or aphides, inasmuch as the hard texture of their leaves does not suit their tastes; but scale, both white and brown, thrive upon them, and must be removed by means of the sponge. Mealy bug will also live on them, and should be removed by laying the plants on their sides and syringing them with sufficient force to dislodge the insects. T. BAINES.

The Size of Wire for Garden Walls.—I shall be obliged if you would kindly give your opinion as to the use of No. 14 galvanised wire for wiring walls on which Peaches and Nectarines are to be trained. There appears to exist in the minds of some a difference of opinion as to its being strong enough for the purpose, especially in the case of old trees.—M. H. [For strong old trees a size or two larger would be better, but as trees on walls are frequently not of this character the size named is usually sufficient. In French gardens, where this wire is much used, erect rods cross the horizontal wires, and on these upright rods, held in position by the wires, the erect branches of the trees are frequently trained. It is well to bear in mind that training young trees on the wires is very different from forcing old branches to assume a new position on slender wire.]

Fruit Prospects.—I am happy to be able to report that our prospects for a fruit crop are still favourable. The thermometer fell on two occasions last week to 24°, but Peaches and Apricots, are, I think, quite safe under Brittain's netting, and similar protective contrivances. But what a month of storm and wind it has been! Living beside the Fens is, as regards exposure, worse than the sea-side.—E. HONOUR, *The Gardener, Lunsey Abbey.*

VEGETABLES AND FRUIT IN CONSTANTINOPLE.

The cultivation of vegetables and fruit in Constantinople, like every other species of culture in the unhappy country of which it is the capital, is carried out on the most primitive and unscientific principles. The system of horticulture pursued by the natives (under which head I include the whole of the heterogeneous mass of races constituting the Ottoman Empire) is convenient and inexpensive, inasmuch as it consists in little more than allowing things to grow in their own way. Melons, Egg-plants, Grapes, Figs, Cauliflowers, and one or two other useful fruits and vegetables which in that favoured climate almost grow of their own accord, are all super-excellent; but those members of the fruit or vegetable kingdom that require a degree of attention and experience, such as Peaches, Plums, Carrots, or Potatoes, in fact, anything that cannot be left to shift for itself during the best part of the year, yield a result that may be readily guessed at.

The causes of this apparent apathy on the part of the market-gardeners of Constantinople and its neighbourhood are not far to seek. The City of the Sultan has long since earned the well-merited reputation of being the head-quarters of extremes and anomalies of every description; it can hardly be wondered at, therefore, that the "Gate of Felicity," as the Osmanlis affectionately term their capital, should frequently be the victim of meteorological irregularities of no common order. These eccentricities on the part of the "Clerk of the weather" can readily be accounted for if we consider the geographical situation of Constantinople. A reference to Keith Johnston will show us that Constantinople is nearly on the same parallel of latitude as Naples, Barcelona, and Oporto; but far away on the northern side of these cities, as for instance at Mentone and Nice, we find the Olive, the Orange, the Lemon, the Prickly Pear, the Palm, and half-a-dozen other semi-tropical plants increasing and multiplying, while, with the exception of the Melon and the Pomegranate, there is but little difference in kind, at any rate, between the vegetable productions of Constantinople and those of Fulham or Charenton. Another glance at the map of Europe will reveal the cause of this apparent anomaly, and show the reason why Constantinople does not act up to its latitude. If we draw a straight line from the centre of Stamboul to the North Pole, we shall hardly meet with a chain of hills 1000 ft. high along the whole of the 49°. Consequently the wintry northern blasts, sweep down upon the Bosphorus and its neighbourhood with almost polar severity; and were it not for the warming effect of the Black Sea and the slight amount of shelter afforded on the north by the low hills which form the tail of the Little Balkan range, Constantinople, during the first three or four months of the year, would be a very good imitation of Moscow or St. Petersburg. If we take the mean winter temperature as determined by Professor Berghaus, of Berlin, and MM. Coumbar, Ritter, and Lyne, of Constantinople, we shall find it lower than that of the south-west of Ireland and Cornwall, and closely approximating to those of London and Paris. The mean of the whole year approaches that of the centre of France, while the summer mean is higher still, placing Constantinople on a level with central Italy and Spain. Autumn and spring can hardly be said to exist as seasons, for summer is no sooner ended than winter begins, and the change from winter to summer is effected with all the celerity of a transformation scene in a pantomime. An instance of these sudden changes will suffice. One Wednesday towards the end of last April I crossed the wooden bridge from Stamboul to Galata, and although I was well great-coated and comforted, the northern blast which was blowing in my face was so keen that my cheek-bones ached with the cold. On the Sunday evening after I sat out on the open terrace on the top of a friend's house, drinking tea and chatting in the balmy moonlit air until nearly midnight. Added to all this, the winter, though short, is late, and the summer is long, hot, and dry, it frequently happening that not an inch of rain falls for six months. Your readers will, therefore, readily understand that the difficulty of growing ordinary European fruits and vegetables is by no means slight. In addition to this, the supply of water, whether from natural or artificial sources, is of the meagrest description. Night dews during the summer are unknown, and the soil being very porous

and light, the effects of the few showers that do fall are transitory. With the exception of the few plants I have mentioned, all the others require the greatest amount of care and attention. With plenty of warmth and protection during the winter, and water and shading in summer, as good Peaches and Apricots can be grown, and are grown, in Constantinople, as in England or France, but, except among rich amateurs, all this care and attention are wanting. The gardeners attached to the English, French and Russian Embassies, the palaces of the Sultan, the ministers, and others have abundantly proved that the fickle climate of Constantinople may be conquered by perseverance and experience, but, in addition to these two important qualifications on the part of the horticulturist and his assistants, a third is wanted on the part of the proprietor—a well-filled purse. This being the case, it may seem strange that no capitalist has yet been found to carry on market-gardening and fruit-growing on the same scale as in England and France, but the mystery is easily solved, and is to be sought for in the single word "cheapness." A native of the Sultan's dominions, be he Turk, Greek, or Armenian, cares but little about the quality of a product so long as it is cheap or even apparently so. Offer him hard unripe Peaches, or half-rotten Tomatoes, say at 1d. per pound, and he buys readily enough after the customary amount of higgling; but improve the quality tenfold, and ask him double the price, he either offers you half or turns on his heel, with the idea that you take him for a fool or a Frank—terms of equal signification in his eyes. Hence there is no stimulus for the fruit-grower or the market-gardener to produce good fruit or vegetables at a heavy outlay for labour and plant. If by letting his Peaches, Plums, and Pears grow at their own sweet wills, he can sell them ten days before they are ripe at what he calls a good profit, why should he be expected to spend money, time, and labour in producing fruit which he could not sell at all?

The above is no imaginary example, but is the result of a conversation I had last year with an intelligent Greek farmer, who, having read in a French gardening book that the proper way of growing Peaches was to prune the trees carefully, and train them against the wall, forthwith adopted this principle, instead of allowing his Peach trees to grow like Holly bushes. The first year his Peaches were burnt up; the second he shaded them during the hottest season, and produced excellent results, as far as the fruit was concerned, which had only one fault—it was unsaleable because it was too dear; the third year, therefore, he threw down his walls, and went on growing Peaches in the old way. After what I have said, it is scarcely necessary to remark that hot-house produce would never find a sale in the market, and that such things as forced vegetables or fruits are utterly unknown, any tendency in this direction manifesting itself in an overweening desire to burn fruit into cash at the earliest possible moment, the consequence being that a really ripe Peach or Plum is a rare commodity. But it is time to speak of matters of detail.

The growing of vegetables, fruits, and flowers in and around Constantinople is carried on principally by Bulgarians and Albanians, these two closely-allied sections of the Slavonian race having apparently constituted themselves the tillers of the soil throughout Turkey in Europe and the northern parts of Asia Minor. A Bulgarian or Albanian who has served his easy apprenticeship to gardening, either in town or in the provinces, generally manages to save a few pounds by the time he is one or two-and-twenty, for both are thrifty, sober, and plodding specimens of the human race. He forthwith rents a piece of ground, possibly from his former master, and commences business for himself in a small way. If he be poor, he rents a cheap plot in some hot and dry situation in the centre of a valley exposed to the sun, or on the side of a hill having a southerly aspect, in order to grow Melons, Egg-plants, Tomatoes, and other produce which cost a mere nothing in money or attention for their culture, and which always command a ready sale. If, however, his pockets be more warmly lined, he hires a plot in some of the numerous alluvial valleys with which the neighbourhood of Constantinople abounds, with a share in the neighbouring well, and builds himself a shanty about as large as a good-sized dog-kennel. He then sets to work to grow Lettuces, salads of various kinds, Artichokes, Cauliflowers,

Onions, and possibly Apples, Pears, Peaches, and Cherries, all of which require coolness and moisture. As soon as his crops have nearly come to maturity they are bought at a low rate by some usurious Greek, Armenian, or Jew, who has possibly advanced him the money for his few tools and seeds at an exorbitant rate of interest, and who again sells, of course at a large profit, to the costermonger or greengrocer. This system, however, is falling into disuse near the capital, and the custom of letting and sub-letting is slowly disappearing. Although but little general improvement seems to be taking place in the system of cultivation for the reasons stated above, large holders growing and selling their own produce are on the increase. For instance, a Turkish friend of mine, a staff officer, inherited a portion of an alluvial valley not far from the Black Sea entrance to the Bosphorus. It struck him that, as it already produced a fine crop of Grass, it might grow other things of a more useful nature, and, as there were no cattle or sheep in the neighbourhood that could graze upon it, might be turned into a market garden. Being, like most Osmanlis, of a cautious nature, he began by clearing a few rods and sowing Lettuces and Cabbages, which succeeded so well that he at once sank a well and commenced operations as a market gardener. Being, like many of the modern Turks, a firm believer in everything French, he sent to Paris for all the best works on vegetable and fruit culture, and set to work in good earnest, and on proper principles. The common produce he disposes of at a good profit in the neighbourhood, and the more choicely cultivated fruit and vegetables to the numerous rich Beys and Pashas with whom he comes in contact in his official position, such traffic not being at all looked on as *infra dig.* on the part of a Turkish officer bearing the rank of staff-major. The first vegetables that claim our attention are those belonging to the Melon, Vegetable Marrow, and Egg-plant classes. These are numerous in variety and excellent in quality; and with Grapes, Olives, and baked or boiled Maize, form the staple food of the lower classes for at least nine months out of the twelve. They mostly possess the valuable qualification of growing almost anywhere, and of producing a good crop with a minimum of attention. I have tasted excellent Water Melons which had sprung up quite spontaneously on a heap of brick rubbish, the remains of a fallen wall.

The Melon trade of Constantinople is a peculiar one. About the beginning of August every scrap of waste ground in the more populous parts of the capital is let by the Municipality to the Melon sellers, and the erection of wooden shanties of the most fragile description immediately commences, which serve for store, shop, kitchen, parlour, and all. If the buyer wish to consume his purchase on the premises, he is accommodated with a stool, and when he has finished his Melon he can order a small cup of black coffee and the customary glass of water from the nearest café. The Melon seller is generally a picturesquely clad Greek or Armenian from the shores of the Sea of Marmora, who undertakes to sell the produce of his particular district, which is shipped to him from time to time while the season lasts. On the other hand, many Melon vendors dispose of their own produce, or simply buy in the open market. Immense quantities are also disposed of by the native costermongers whose name is literally legion, Constantinople being the paradise of street-sellers of all descriptions. The Water Melons seem to be of only one variety. They are generally "round like an Orange and a little flattened at the poles," and of an even fresh green tint, but sometimes streaked or speckled with lighter or darker markings. They vary in dimensions from those of a racket ball to those of a large football. The flesh is of a reddish-purple hue in the centre, shading off to greenish-white at the circumference, with dark purple or black pips. They are generally eaten without any condiment, but a dash of pepper is a good preservative against after-consequences. In rich Turkish houses they are cut in slices and frozen in an ice-pail, and, as may be imagined, form a most refreshing morsel in the hot weather. The sweet Melons are most various in size, shape, colour, and flavour. The finest are undoubtedly those grown at Cassaba, near Smyrna, which are, of course, correspondingly dear, and being dear are scarce.

Vegetable Marrows, too, vary in size and shape from a small variety of about the dimensions of Inspector Bucket's

fat forefinger to the Ohio species, which often grow to the length of 6 ft. or 7 ft., and 2 in. or 3 in. thick. When peeled, cut into lengths 1 in. or 2 in. long, and stuffed with force-meat, boiled, and served with white "sauce piquante," they form a delicious dish. The seeds are hard and indigestible even when young, and are always scooped out and thrown away. Our own varieties of Vegetable Marrows are good and cheap.

There are two kinds of Egg-plants—one the ordinary Aubergine of the South of France, which is used in enormous quantities for stews and as an ingredient in meat stuffing, of which there are fifty different kinds; and another, somewhat resembling a stonemason's mallet, which is apparently much relished when fried in slices. These two varieties of the Egg-plant are confused by the Turks under the common name of "patlijan," a corruption of the Persian word "badinjan," which means the "soul of wind," an epithet conveying an exact idea of the effects which these vegetables have on those who are not accustomed to them. Next comes the Tomato, which was introduced from Southern Europe some three centuries ago under the name of "frank patlijan," or Frank Egg-plant. It also is used in enormous quantities, being one of the cheapest of cheap vegetables. Last summer being unusually hot and dry, Tomatoes were very plentiful, and were selling in the streets of Stamboul at 10 paras (less than a halfpenny) per oke, *i.e.*, 283 lbs. There is also an immense consumption of Artichokes, which truly merit the name of "delicious Thistle" bestowed on them by old Evelyn. They are generally boiled and eaten cold, with oil and vinegar, and are a great Lenten dish with the Greeks and Armenians. During the spring, and indeed all through the summer, Cos and other kinds of Lettuces are most abundant; but to any one accustomed to London or Paris salads, they taste flabby and leathery. Cabbages and Cauliflowers are excellent, particularly the latter. Carrots, Turnips, Radishes, and Parsnips are all small and woody. Onions and Leeks are super-excellent, especially the former, which are peculiarly delicate in flavour. The "bamia" (*Hibiscus esculentus*), or Gombo, as it is called in the West Indies, is largely cultivated. It resembles in size and shape a five-sided tenpenny nail, and is largely used as an ingredient in soups and stews. Owing to its gelatinous nature, it is not much relished by Europeans. It is also plucked young, when about half-an-inch long, and dried for winter use. Peas and Beans are fairly good. A species of Pea, which is gathered young and stewed in the pod with meat is 'excellent in flavour. Cultivated Asparagus is almost entirely unknown. The wild plant is found in the neighbourhood of the city, and is gathered and sold in the streets, as Groundsel and Chickweed are in London. It makes an excellent foundation for vegetable soup. The Chick-pea is also largely eaten by the lower classes, both boiled and parched. When gathered young and boiled, it closely resembles our Marrowfat, and is much superior to the ordinary Pea as grown by the Constantinople market-gardeners; but as only one or two Peas are contained in a pod, it is troublesome to shell.

Of fruits, the chief is undoubtedly the Châouss Grape, of whose excellence every traveller has spoken in terms of well-merited praise. The Châouss or Sergeant Grape is grown along the shores of the Gulf of Nicomedia, and from the beginning of September to January and February is eaten in enormous quantities by both gentle and simple. It is a white Muscat oval Grape, and, when in perfection, is universally allowed to be unsurpassed by the Grapes of any other country in Europe. The Sultanieh or Sultan's Grape, which, when dried, forms what we miscall Sultana Raisins, is brought in large quantities from Smyrna. It is a most delicious little Grape, and, from the thinness of its skin and the absence of stones, is more easily eaten by those who have not acquired the Turkish habit of swallowing skin, stones, and all. Figs, of which there are several varieties, Quinces, which are much used in cookery, Oranges, Lemons, and Pomegranates are all good and cheap, but our usual western fruits, such as Pears, Apples, Peaches, Plums, Apricots, Currants, Gooseberries, Cherries, Raspberries, Strawberries, Walnuts, Filberts, &c., are all far below mediocrity. The black Mulberry is good and abundant, but the white species, which the natives seem to prefer to the black, approaches in flavour to a lump of sweetened

blotting-paper. A kind of Morello Cherry, called by the natives "vishnah," although unfit for eating, is largely used for making a preserve, which, dissolved in water, forms ordinary sherbet, the common drink of the sober Mussulman lower orders at all seasons of the year. C. W. QUIN.

FRÖBEL'S BEGONIA OCTOPETALA.

THE extremely unfavourable impression which this plant made not only on myself, but also on everyone whom I have heard mention or allude to it since it was re-introduced in 1873, and the great apparent inferiority of the reality to the beautifully-coloured plate issued by the Zurich firm (which undoubtedly promoted the sale of the plant), and which was said to be an exact and faithful reproduction of the description of the flowers sent home with the tubers by M. Roelz, but which our experience hitherto seems to prove greatly flatters them by giving a deep crimson under petal, when the reality is a dingy greenish tint; the individual blooms, appear also much larger and of a purer white than they really are, resembling, as they do, only an inferior form of *Anemone japonica* Honorine Jobert—all these facts make me think that a large number of your readers who take an interest in these plants may like to hear what M. Fröbel says concerning this at present unappreciated novelty, which apparently has not yet been seen at anything like its best by British cultivators. In the first place, he asserts that this variety is naturally very late in starting into growth, usually showing no signs of commencing to grow till the end of June or beginning of July, and that it is most injurious to the tubers to attempt in any way to force them into premature growth by any form of artificial heat. That the flowers do not appear till the month of October, and that they are rarely fully developed before November, a season when nearly all other varieties of tuberous Begonias have finished their five months' season of bloom and are going to rest again for the winter. All blooms of *Begonia octopetala* produced before the end of October or beginning of November are, according to M. Fröbel, poor and inferior in quality and substance. He concludes by stating that it is his firm conviction that the horticultural public will be delighted with *Begonia octopetala* when they understand that it is practically a winter-blooming species, its proper and natural period of growth being between the months of July and January, and that during the remaining months of the year it is absolutely necessary to allow the tubers to remain in complete repose. He also says that when put into the open air it dislikes the full glare of the sun, and should be so placed that only the morning sun shall shine upon it. M. Fröbel also now sends me another variety, which I had not hitherto heard of, under the name of *B. octopetala rosea*; it may turn out that this is the variety from the description of which the plate published with *B. octopetala* was prepared, and that, through some misconception or mistake the tubers of the wholly white variety were distributed instead of those of which the plate was a representation. When both the varieties flower I shall be able to let your readers know whether this supposition proves correct or not. M. Fröbel also informs me that he has already obtained some most interesting and curious hybrids between *B. octopetala* and the fine glaucous hairy-foliaged *B. Fröbeli*, of which he invites inspection from any lover of flowers visiting Zurich in the course of August or September next. W. E. G.

Honeysuckles in the Dwelling-house.—Some years ago, as I was passing through a room only used occasionally, I perceived an odour of fresh flowers that surprised me, as none were ever kept there; but, being in haste, it soon passed from my mind. Not long after, being in the room, I noticed the same perfume again, and this time I proceeded to investigate the matter. On raising the curtain of the east window, I found that a branch of Honeysuckle had found its way between the two sashes at one corner while growing in the summer, and had extended itself quite across the window; and on the branch inside there were three or four clusters of well-developed flowers, with the usual accompaniment of leaves, while on the main bush, outside, there was not as yet a leaf to be seen. The flowers inside were just as beautiful and fragrant as if they had waited until their natural time of blooming. Since then I have tried the experiment purposely, and always with the same result.—M. A.

Davallia Moorei for Rooms.—Mr. Herbst informs us that *Davallia Moorei* is one of the very best plants he has met with for thriving in rooms. He also praises the common *Osmunda* for house culture. It is probable there are a great number of Ferns that would thrive in rooms. We do not mean in Wardian or other cases of that kind, but exposed to the dry air of a living room; gas and violent draughts of cold air, however, destructive to these and all other plants in dwelling houses.

NOTES OF THE WEEK.

THE new *Victoria Mignonette* is now grown in pots for the London market by Mr. Herbst, of Richmond. It is remarkable for its rigid erect habit and flowers, large and even showy compared with the elder form.

WADSON'S WHITE is the name of a Pink of singularly white and beautiful character which is now sent to Covent Garden in small quantities by Mr. Lee, of Arundel.

THE rich effect afforded by bunches of Violets, plunged in masses of double or single Daffodils, that one may occasionally see in the barrows early in the morning at this season in Covent Garden is very striking. It is suggestive, also, of the effects that might be obtained by design while dealing with like materials either in a cut or growing state.

MR. ROBSON, of Linton Park, considers that the presence of certain plants indicates a soil suited for the *Rhododendron*, and he mentions that the Foxglove, Heath, Brake, Gorse, Broom, and Scotch Fir grow naturally on soil suited for that shrub. Mr. Robson's opinions are worthy of great respect in such matters, but we think this test will not in all cases hold good. We have seen *Rhododendrons* perish miserably in soils on which several of the above subjects grew wild in abundance.

THE sprouts from various races of the Cabbage tribe in cultivation seem now to be of even greater value than the heads. What with Broccoli Sprouts, and sprouts and tops of various kinds, the London market is now never without abundance of a variety of the most delicate greens in winter and spring. No plant has done more to improve the food supply of the world than the cliff-dwelling *Brassica oleracea*.

THAT there is hardly any limit to the modification and improvement that may be effected in flowers, would seem to be proved by some strains of the *Cineraria* now in flower round London. Their richness and purity of colour are astonishing, even when seen side by side with the showiest blossoms we possess. Many of their flowers look as attractive by artificial light as in the daytime. A very fine and varied strain is now in flower at Messrs. F. & A. Smith's Nurseries at Dulwich.

THE many choice and very expensive evergreen plants in Leicester Square now look as if they had been caught in a prairie fire, which had been swiftly extinguished by a water-spout. No neglected deciduous trees seem half so miserable. It is sad to observe the way in which myriads of evergreens are yearly planted in London by men who must know that it is worse than useless to plant them. There is, after all, some work to be done in the horticultural tree by the knife of the "Saturday Reviewer," if he only knew the worthless and cankered branches.

WHATEVER may be the virtue of the Cocoa-leaf in S. America to increase the powers of endurance in prolonged muscular exertion, it seems, according to the "Lancet," to have lost much of its marvellous virtue when used in this country. A popular rumour attributed Weston's success in walking to its effect; but it appears that he not only owes none of his power to its influence, but found that, on the whole, it rather lessened than increased his strength. It acted as an opiate, and forced him to sleep. A previous trial in America had the same result. The Cocoa-leaf was tried extensively some years ago by Dr. Buzzard in epilepsy and other forms of nervous disease, but with no striking results. Some patients while taking it described its effect as resembling that produced by wine or spirit; but there was no objective result to encourage its continued administration.

CROCUS TRUSCUS (Parlatore), which has only hitherto been known to science by Professor Parlatore's description in "*Flora Italiana*," vol. iii., p. 223, and three or four specimens in the Florence herbarium, gathered by Professor Parlatore in the spring of 1858, was re-discovered by Mr. George Maw, of Benthall, and Mr. S. Sommier, of Florence, early in the present month. It grows in tolerable abundance in Oak woods, at the Salita del Filetto, near the road, about 7 miles from Massa Marittima, on the road to Pomerance, in the Tuscan Maremma, and not as indicated by Professor Parlatore between Follonica and Massa. There appears also some error in Professor Parlatore's record of the date (April 9), 1858, as in the second week of March, when gathered by Messrs. Maw and Sommier, the plant was nearly out of flower, and most of the specimens had well-matured seed. It was also observed in a field near a little farmhouse, known as Poggio di Venti, between Massa and the original station, and was said by the country people to be not unfrequent in the Tuscan Maremma. The flower closely resembles that of *Crocus suaveolens*, but the twines of the corolla are strongly reticulated, though not quite so coarse in the fibre as the twines of *C. reticulatus*.

THE FLOWER GARDEN.

A NEW SNOWDROP.

(*GALANTHUS ELWESII*.)

We recently saw this fine form of Snowdrop in flower in Mr. Barr's bulb grounds at 'ooting, from whence flowers were obtained from which our engraving was prepared. It is, perhaps, the finest of all our Snowdrops, its nearest ally undoubtedly being *G. Imperator*, but in that variety the green

Galanthus Elwesii.

blotches at the bases of the three inner segments of the perianth are wanting. It may be at once distinguished from the common Snowdrop by its larger size, and from *G. plicatus* by its more glaucous unplaited leaves, but it seems very questionable to us whether all the Snowdrops are not forms of the same species, seeing that there is but little structural difference among them, the main points of distinction being size of flower, and a slight difference in the depth or arrangement of the green blotches of the inner segments. As a garden plant this Snowdrop will be most welcome when

more plentiful, not only for planting in patches among the herbage, on outlying portions of the lawn, or wherever the less conspicuous common form is usually to be found, but also for use in bouquets and for decoration. The bold and finely-moulded outer segments are of crystalline whiteness, and the flowers of it which we obtained for sketching kept perfectly fresh for more than a week in a glass of water. Nothing could look prettier than they did, their snowy segments contrasted with Violets and a few sprays of Maiden-hair Fern.

B.

SCILLAS IN THE WILD GARDEN AND IN BORDERS.

Amongst early flowering bulbs there are few more cheerful or useful than the different species and varieties of the Scillas; and they may be grown as well or better amongst short herbage as in the flower garden proper. There appears to be some confusion in the nomenclature of these bulbs, and probably the same species often go under more names than one; but many of the varieties are so alike, if not allied, that until the genus is taken in hand by some competent authority, this is probably unavoidable. We will begin with *Scilla amona*; it is scarcely so hardy as some of the others, at all events, in heavy soil; its flowers, which appear about the end of April, are of a dull blue, with a darker line of the same colour running through the middle of each petal, growing in spikes to the height of 9 in. or so; it requires a light well-drained soil, and a position somewhat sheltered. Next comes *S. bifolia*, flowering in March with spikes of a fine blue; it has been found growing apparently wild in this country, but is probably not a true native, having escaped from cultivation; the leaves are, as a rule, two in number, of a pale green. There is a white variety equally good, and the two colours should be mixed together in planting; also a rose-coloured one (*S. bifolia rubra*), but the last I have found difficult to obtain, the rose colour often turning out to be blue or white. This species is useful for forcing. *S. campanulata* is a strong-growing and handsome kind, and very valuable for planting in shrubby borders or wild gardens, where it will not fail to bloom plentifully and constantly every year about May; the flowers are bell-shaped and pendent, arranged in pyramidal clusters. There are several varieties, blue, white, and rose-coloured, and all are equally free in growth and desirable. *S. campanulata major* is larger and finer than the type, but is otherwise identical. *S. amethystina* is more usually known as *Hyacinthus amethystinus*, and is a very pretty bulb for the mixed border; the flowers are pendent, in loose clusters, of a beautiful blue; the leaves (which are longer than the flower-stem) are very narrow, and the plant is about 9 in. in height. *S. nutans* is the common Bluebell, which should be abundantly naturalised wherever it does not occur wild. Many persons, probably, are not aware that there is both a white and also a pink form, which should always be associated with the old kind. Of quite a different appearance is *S. peruviana*, with its large head of glistening blue flowers, in a perfectly regular, closely packed pyramidal cluster. Each flower is immensely set off by white stamens, making a most pleasing contrast; the leaves are of a shining green, broad, and longer than the flower-stem, and the bulb is larger and pear-shaped. Whatever other species may be omitted from a collection, this should never be absent. It comes from the south of Europe, but is perfectly hardy in this country, and increases rapidly. There is also a white variety, which, though inferior, may be grown in a large collection. Last, but not least, is that most charming little spring bulb, *S. sibirica*, from the Caucasus, Asia Minor, and adjoining countries; its flowers, which appear before the leaves, are pendent in a loose cluster, and are of the most intense and brilliant porcelain blue. It is a most valuable plant for edgings to beds of spring flowers, or for planting in tufts in the borders, and may also be introduced where the turf is dwarf without misgivings as to its success; and, as it blooms in the bleak month of March, it is doubly valuable. It is better to separate the bulbs every third year, as they increase rather freely if in a good sandy loam. *Scilla præcox* I take to be identical with *S. sibirica*, or at most a trifling variety of it. While on the subject of Scillas, I will mention a plant of the same family (the Asphodel), namely, *Puschkinia*

Scilloides, which may be associated with them. It is a pretty bulbous spring-flowering subject, about 4 in. high. The flowers are cup-shaped and whitish, with a blue stripe, and shaded with the same colour in each petal, arranged in a terminal corymb of about six blooms. The stamens are curiously united together. Plant it in the choicest border, in sandy loam, until the supply is plentiful, and increase by separating the bulbs every third year.

OXON.

LAUREL BANKS IN PLEASURE GROUNDS.

Few shrubs are more effective than the common Laurel, its bright green foliage rendering it attractive at all seasons, and the facility with which it may be trained into any required form, more especially into dense evergreen banks, has caused it to be planted abundantly in pleasure grounds, sometimes even to the exclusion of equally effective subjects. In speaking of Laurel banks I refer to such as are planted on level ground and trained in a flat fashion, a form which has, however, some disadvantages, inasmuch as it is not only badly adapted for showing off the individual beauty of the plants, but the erect-growing branches deprive those at the base of their proper amount of sap. A Laurel bank, as usually seen, consists of one or more rows of plants trained so as to form a flat face or surface, more or less upright, and generally from 4 ft. to 7 ft. in height; the more erect the form of training the sooner the bottom branches begin to decay, and gaps more or less extensive to occur, thus disarranging the whole effect, as upon the perfectly furnished character of such banks from base to summit rests their beauty, and it is no easy matter to fill up gaps effectively under such circumstances. No shrub or tree is more benefited by judicious pruning than the Laurel, for if kept thinned out so that the young growths at the base of the plants get the benefit of light and air, there is scarcely any limit to its longevity. But when trained to a flat face, all the growth is made at the extremity of the branches, which forms so dense a shade that the lateral growths necessary for filling up vacancies perish from want of air and ventilation; consequently there is no reserve or undergrowth to fall back upon when gaps occur, and the only remedy consists in cutting the whole down to the ground and starting afresh. This is one only of the many instances that might be cited of the folly of introducing what are termed permanent features, or rather those intended as such, into gardens and pleasure grounds, that may suddenly fail or become an eyesore. Alterations in such cases mean a serious blemish for years which might be avoided if a more unfettered system of planting were adopted. The Laurel, as I have stated, is of so tractable a nature as regards cutting that it may be kept for an indefinite period pruned to within a foot of the ground, and on undulating surfaces it forms one of the most pleasing of evergreens for ground work. My impression is that shrubberies might be greatly enhanced as regards effect by the employment of leaves and flowers as varied as possible in character, and by a somewhat more liberal use of flowering deciduous shrubs than we now employ. To indicate their individual beauty effectively, neither rows nor patches are needed, but a judicious blending, so that there may be individual effects and yet a harmonious whole. In order to form such a combination, a thorough knowledge of each particular shrub used is necessary, and also the space which they are likely ultimately to occupy. The Laburnum, Guelder Rose, Lilac, and Syringa are all improved when associated with the bright and cheerful shining foliage of the Laurel, and in no shape more than in that of a spreading bank. Isolation is not nearly so good as combination; in short, variety is always pleasing, and in garden scenery should be specially studied.

Henham.

J. GROOM.

Pelargonium Happy Thought.—A short time ago reference was made to the origin of this Pelargonium. From what I can learn it was raised in this neighbourhood by a Mr. Lynes, The Hamlet, Leek Wootton, Warwick, who is a jobbing gardener and an expert budder and grafter. It was not a seedling, but a sport from the old Pelargonium magenta. It was circulated about, though never sent out by any particular firm as a plant of any merit, though it well

deserved to be. It is quite distinct from other Pelargoniums in cultivation. It is an excellent bedder, and no doubt we shall hear more about it when it is better known.—R. GREENFIELD, Warwick.

ROSES FROM CUTTINGS.

MR. W. TAYLOR makes a good defence of these in the "Journal of Horticulture." Roses, he says, are grown for other purposes besides exhibiting, and for all such other purposes I have no hesitation in saying that where there is a good natural Rose soil, *i.e.*, a clayey loam such as the hedgerow Briar delights in, that Roses on their own roots are decidedly the best. They do not produce a large flower or two and then bid us good-bye, but go on increasing in size and beauty year after year, and produce blooms by the hundred, filling the air with their fragrance. Last November I planted 250 plants which had been put in as cuttings exactly two years before. They are planted 3 ft. apart every way on a border of very stiff soil, and I expect them nearly to cover the ground this coming summer, and that without any tying or pegging. These were selected from some 400 or more struck at the same time. I have older plants in great numbers which made growths last summer from 6 to 8 ft. in length, and although the season was a cold one the wood is tolerably ripe; and what is a special advantage this year, there are dormant buds to prune to, which on standards are rather too scarce. My pot Roses for forcing are mostly on their own roots, and those which are not so are decidedly inferior to the others. I cannot have the newer kinds this way, but for my purpose old varieties, if they be good, will do just as well. During the London season I have to supply abundance of flowers for the dinner-table. A table for twenty or more people twice a-week has to be covered, excepting a few inches at the edge, with flowers of one, or at most two colours, and Roses, of course, are preferable to anything else. On one occasion last year I sent 900 blooms of Gloire de Dijon; on another as much Stephanotis as would fill two bushel baskets, and sufficient pink Roses to make an outside line; at another time it would be crimson Roses, and so on. I say nothing about the taste of such arrangements, I have simply to obey orders. Now it is plain that such a demand could not be satisfied with a few hundred standards. No; the point to aim at is to have Rose bushes as big as our Rhododendrons, which, I am happy to say, I am in a fair way of doing. Why not use more Roses in shrubberies and by woodland walks? Have them on their own roots, and do not prune too much. Nearly all the Perpetuals are as hardy as the common Briar—if they are not coddled up. They would not, perhaps, be prettier than the single Briar in like positions, but their flowering season is longer, and they are mostly sweeter. Rose cuttings of the Perpetual class should not be put in under glass, but more in the way of Gooseberry cuttings in November, and the wood must be ripe. Teas strike best from half-ripe wood in July and August under hand-lights against a north wall.

Gladioli in Trenches.—I prepare these as follows:—I commence by opening trenches, the same as for Celery, about 15 in. deep, 12 in. wide, and 2 ft. apart. I then put 5 or 6 in. of well-rotted manure from an old hot-bed in the bottom of the trenches; with 2 in. of earth, and 2 in. of sea-sand. I then place the bulbs about 15 in. apart on the sand, and cover them with 2 in. more of the same material, filling up with the earth taken out of the trenches. Formerly, the bulbs used to be destroyed by a kind of maggot, and many were badly diseased; but since I have used plenty of fresh sea-sand, I have not seen a diseased bulb or a maggot amongst them. In autumn, when the stalks have turned yellow, I choose a dry day to take them up, and lay them out thinly on the floor of a loft over the potting-shed, where they remain until planting-time comes round again. I have just finished planting nearly 300 bulbs in this manner.—JOHN CLARKE, Cork.

SWEET IS THE ROSE.

Sweet is the Rose, but grows upon a tree;
Sweet is the Juniper, but sharp his bough;
Sweet is the Eglantine, but pricketh near;
Sweet is the Firbloom, but his branches rough;
Sweet is the Cypress, but his rind is tough;
Sweet is the Nut, but bitter is his pill;
Sweet is the Broom flower, but yet sour enough;
And sweet is Moly, but his root is ill;
So every sweet, with sour is tempered still,
That maketh it be coveted the more;
For easy things that may be got at will,
Most sorts of men do set but little store,
Why then should I account of little pain,
That endless pleasure shall unto me gain?

EDMUND SPENSER.

THE KITCHEN GARDEN.

CROPPING THE KITCHEN GARDEN.

In the kitchen garden March begins the gardener's year, for upon the work, well or ill executed in this month, depends much of the success, or even the actual forthcoming, of many crops throughout the coming season. As the questions of arrangement of space for the various crops and the general first sowing of seeds will be now forcing themselves upon the mind of every gardener, a few remarks relating thereto may not be inopportune. First, then, we may consider the succession of crops, which should always be the key to a general systematic plan for the year, and then recapitulate what seeds may now be sown, and in what manner, at the same time premising that these remarks will only apply to private gardens. In proposing rules for crops in succession the nature of the soil must be taken into consideration; light friable soils, which are amenable to the spade at any season, are altogether more manageable than chalky soils or heavy clays; in the latter case general digging in spring or summer is a positive evil. Take, for instance, some ground which has been under Strawberries for three years; if the land be of a friable texture, there will be time for the general crop of Celery being planted in it; if the soil be a heavy clay Celery would not succeed in it, but a late crop of Broccoli might be planted in it after clearing the surface and without any digging, with every prospect of a good crop, preparing it afterwards for Celery in spring. Celery is a most useful crop to start with, because the land must necessarily be well stirred and manured; the Onion crop may follow the Celery, distributing the remains of the decayed manure from the trenches on the surface; when the Onions are removed in early autumn spring Cabbages may be planted out; ground that has been occupied by Carrots, Parsnips, or Beet, after manuring, will be in condition to receive Brussels Sprouts, which should always be planted early, and about 3 ft. apart each way; this land, if heavy, after having been well-manured in autumn and ridged for the winter, would by this time have become mellow and suitable for Peas. Peas may also succeed Celery, to be again followed by Broccoli, Winter Turnips, or Spinach. On clayey soils Turnips may follow Strawberries by simply clearing them off and spreading some leaf-mould on the hard surface, drawing lines and sowing the seeds: Turnips do well in the autumn if sown on a hard surface with the requisite moisture; ground from which Asparagus or Seakale has been removed for forcing, is in good condition for early Cauliflowers, the annual top-dressing given to the land for the former being highly beneficial to their growth; Strawberries will thrive well in such soil with little preparation except trenching. After early Potatoes have been dug, plant late Broccoli, Savoys, Turnips, and Winter Spinach, the latter requiring a dry open situation. Carrots, Parsnips, Salsify, and more especially Beet, should always have the ground prepared for them by trenching without adding any fresh manure. Parsnips grow large and succulent when the soil is moist and cool underneath, and will succeed well in ground that has been well manured for Broccoli or Cabbages. Shallots, Garlic, underground Onions, pickling Onions, and Tripolis may succeed Lettuce, Endive, or Turnips on borders; Winter Lettuce, Endive, and Parsley, after early Potatoes, Cauliflower, and Shallots. French Beans, as a rule, require the ground to be specially prepared and reserved for them on a warm, sheltered aspect. Runner Beans should be sown in single rows, as divisional or boundary lines, to give them room and plenty of air. The tops of Celery ridges suit Lettuces exceedingly well, as they thrive better on a dry position, if the soil be deep, than most vegetables; indeed, the finest Cos varieties require considerable warmth to bring them to perfection. We may mention that, taken altogether, Brown Cos is the best and hardiest for our climate, and the Paris Green Cos is the variety in the greatest perfection at midsummer.

With regard to the time and the mode of sowing, there are various sorts of main crop seeds which cannot be sown too early; among these are Brussels Sprouts, of which a sufficient quantity should be raised at once, sowing in a frame if possible, if not, in some warm sheltered situation, and transplant as soon as three good leaves appear. We have sown in autumn,

in order to have strong plants early in the north, also sowing a pinch of seed at each place intended for transplantation, afterwards thinning to one, for the stronger the plants become, the more abundant will the crop be in winter. Onions should also be sown directly the soil is in condition; though the Onion crop requires all the summer-heat of our climate to mature, yet the seed germinates and grows under a very low temperature. Sow in lines 1 ft. apart; if the soil be light, it should be well trodden, and dry manure from a pigeon or poultry-house forms a most excellent dressing. Parsley should also be sown early, as the seeds take a comparatively long period to germinate, and does best while the soil is cool; one small bed will supply a large quantity of plants for transplanting into lines. Early Mazagan Broad Beans sown in January are now 6 in. high; Broad Beans should have abundance of room, for without a free circulation of air and plenty of light, many of the blossoms will be abortive. Early Cauliflowers should be sown at once to succeed the spring planting in boxes, and placed in a little heat near the glass; put a little seed under hand-lights in the open ground, also a bed in the open border. A sowing of early white Stone Turnip should be made in very rich friable soil; although a large proportion of them may run to seed (this being their natural seeding season), an effort should be made to have them as early as possible. Early Horn Carrots should be sown on a little heat in a frame, and a few beds in the open air of the same variety; the main sowing should be deferred until the second week in April, or even later, in rows 15 in. apart. On heavy soils the seed should be covered with sifted wood, ashes, and fine soil. Commence to sow Beet about the third week in April. Up to the present date, early and second early Peas will only have been sown, but from the middle of March onwards the more desirable Marrow sorts should only be sown—no variety we have yet seen equals Veitch's Perfection and No Plus Ultra; these should be sown 6 ft. apart between the rows in thoroughly mellow and rich soil, well mulching and watering afterwards. The above are a few of the useful kitchen garden seeds, which require immediate attention; later crops will be discussed at a future time.

W. D. C.

House Sewage in the Garden.—"E. A. H." presents his compliments to the Editor of THE GARDEN, and would be much obliged to any reader who would favour him with information respecting the application of house sewage to garden purposes. Is it suitable for Strawberries, Currants, Gooseberries, and standard fruit-trees, as well as vegetables? In the former case, should it be applied after the fruit has set or at any other special period? And in treating vegetables, should the soil be saturated prior to sowing or after the plant has become established? Will it promote rapidity and luxuriance of growth in the case of evergreens and other garden shrubs?

Celery and Celery Trenches.—I observe that Mr. Thomson (p. 255) asks for any information on this subject, and perhaps the following lesson I learnt from experience may be of some service:—One year I had a lot of fresh and rank manure, and, by way of experiment, put it 1 ft. deep under some Ringleader Peas, which had been sown on a very poor, dry, sandy soil; as soon as the Peas were off, I dug the rows up, and planted them with Cole's Defiance Red Celery, which produced some of the best flavoured Celery I ever tasted, far superior to that grown in the usual manner, besides which the plants did not give the least indication of running. Of course, water was supplied liberally. I do not mean to say that such treatment would be suitable in all soils, but it is simply my experience in the instance mentioned above. I have tried the plan on heavy soil, but with varying results. For light soils I have found Sandringham and Leicester Red very useful, as they are not too tall, and, as a rule, Celeries of a dwarf kind are the best.—W. J. MAY.

Different Kinds of Asparagus.—Evidence in favour of the distinctness of certain kinds of Asparagus seems to be accumulating. There is, I believe, no reason to suppose the plant to be less liable to variation than many others. Will any of the readers of THE GARDEN kindly state their experience of *Comnover's Colossal*?—W. T.

How to Have Globe Artichokes in Succession.—This is a good time to divide and transplant portions of these, as when left undisturbed there is sure to be an over-abundant supply during the middle of summer and a corresponding scarcity later in the season; but by transplanting a portion each year, not only will the plants so treated be greatly invigorated, but the supply of heads will be materially prolonged, as the transplanted ones will come into bearing after the established roots have ceased, and will prolong the supply to a late date.—J. GAOON, *Zenham*.

THE INDOOR GARDEN.

CERATOZAMIAS.

CYCADS present one of the types of vegetation essentially characteristic of some warm or hot and dry regions, but they may be said to represent now more the remains of a prominent feature of a former flora than as belonging to the present epoch. From the occurrence of abundant petrified trunks and leaves, we know that at some very remote period they formed no inconsiderable proportion of the vegetation of this country; now they are associated with fleshy Cacti in Mexico, with Mesembryanthemums, Stapelias, and other succulent plants in South Africa, and with rigid-leaved Proteaceæ, Leguminosæ, and Myrtaceæ in Australia; and outliers of this singular family of plants are found in the mixed vegetation of Japan, India, and some parts of tropical America. The genus *Ceratozamia* is, so far as at present known, peculiar to Mexico, and, like nearly all the members of its family, the species have thick, leathery, and almost woody pinnate leaves. But the horned scales of both the male and female cones furnish

unaided. *Ceratozamia*s, and, indeed, most Cycads, will flourish in a warm greenhouse where the atmosphere is not overcharged with moisture; but they nearly all succeed better in a tropical house, and the higher the temperature the greater the degree of humidity they will bear without injury. A constant dripping of water on the leaves speedily causes decay. The soil usually recommended for this class of plants is a sound loam mixed with a good proportion of sharp sand. They are of very slow growth, and some years must pass before they attain such a trunk as is shown in the accompanying engraving; but they usually stock out at the base, and from their offsets, as well as from seed, they are propagated.

Description of the Species.

C. mexicana ("Annales des Sciences Naturelles," troisième série, vol. 5, t. 1).—Trunk, thick and short, covered with the remains of the petioles of fallen leaves; leaves of a rich dark green, pinnate, borne on long prickly petioles, which are shaggy when young, in vigorous plants often 5 to 6 ft. long; petiole nearly round; leaflets very numerous, 6 in. to more than 1 ft. in length, lanceolate, tapering at the base to about $\frac{1}{2}$ in. in breadth, and upwards into a sharp

Ceratozamia mexicana (about one-twentieth natural size).

the most striking distinctive character of the genus. The first species, and the one upon which the genus was founded by Brongniart ("Annales des Sciences Naturelles," troisième série, vol. 7, t. 1) was introduced by Giesbreght into continental Europe previous to 1846, but the exact date of its appearance in British gardens is unknown to me. Indeed, although *C. mexicana* and *C. Kusteriana* annually produce their cones in this country, none of the species have, I believe, been figured in any of our magazines. Besides the two species named, Miguel, who has devoted much time to the elucidation of the family, has described four or five others, simply from the leaves alone, and therefore some doubts exist as to their belonging to the genus. It is unnecessary to say anything further here respecting the botanical character of the genus beyond the facts that the male and female cones are produced on separate plants, and the seeds are borne two together on the underside of each scale of the female cone, much in the same way as in many of the Conifers. To ensure the fertilisation of the ovules or young seeds, the pollen should be conveyed to the female cones; but the pollen is produced in such superabundance that if male and female plants are flowering at the same time in the same house, and the climatal conditions are favourable, it is almost certain that some of it will reach the ovules

point, traversed longitudinally by numerous contiguous nearly transparent veins, margins closely recurved. Female cone, 9 in. to 12 in. long, by 4 in. to 6 in. in diameter, the scales very prominently two-horned. Male cone narrower and longer, borne on a hairy stalk, scales furnished with two teeth rather than horns. The accompanying figure of this plant is reduced to about one-twentieth of the natural size, and the cones to about one-half. Mexico, introduced by Giesbreght before 1846.

C. Kusteriana ("Gartendora," 1857, t. 185, fig. 17, and t. 186, fig. 25).—Trunk, short, thick, clothed with the persistent bases of the petioles, glabrous; young growing leaves, hairy, ultimately glabrous; petiole, nearly terete, unarmed, traversed longitudinally, as well as the rachis, on the upper side, by two furrows; mature leaves of luxuriant plants, 4 ft. or more in length, with about forty pairs of leaflets; leaflets, nearly opposite, crowded, 6 to 9 in. long, with a long tapering point; male cones, longer and narrower than in the preceding species, erect, shortly stalked, tapering at both ends; scales, furnished with two divergent horns, the upper ones sterile, the lower fertile. Mexico, introduced by Karwinsky. This species is easily distinguished from the foregoing by its unarmed petioles and its smaller opaque leaflets tapering from just above the base upwards to the point.

C. Migueliana.—Leaves, with about five (?) pairs of leaflets, when young, hairy and hoary; petiole, long, nearly cylindrical, very sparse

Female Cone.

Male Cone.

Fruit of *Ceratozamia mexicana*.

ingly beset with prickles near the base; leaflets opposite, or nearly so, wedge-shaped at the base, obliquely obovate, abruptly acuminate, margin thick and revolute, on the lower side towards the tip wary and often furnished with one large tooth. The dimensions of the leaf are approximately $3\frac{1}{2}$ ft. long, on a petiole of 18 in., and the leaflets are 8 to 9 in. long by $2\frac{1}{2}$ to 3 in. broad. This description is borrowed from De Candolle's "Prodrum." The five pairs of leaflets should, doubtless, be fifty. This species is said to differ sufficiently from *C. latifolia* in the length and breadth of its leaflets. Its native country is uncertain, and fruiting specimens alone can determine whether it is correctly referred to this genus. This last remark applies to all the following species:—

C. latifolia.—Petiole, glabrous, cylindrical, more or less prickly; leaflets lanceolate, all except the lowermost nearly equal-sided, 4 to 5 in. long by $\frac{3}{4}$ to $1\frac{1}{2}$ in. broad.

C. longifolia.—Petiole, thickly studded with prickles; leaflets, numerous, narrow, and somewhat obliquely lanceolate; leaves, about $3\frac{1}{2}$ ft. long; leaflets, 15 in. or 16 in. or a little more in length by an inch or more in breadth. *C. intermedia* is regarded as a small variety of this species.

C. robusta.—Petiole, stout, prickly; leaflets, lanceolate, nearly equal-sided, very falcate before they are fully grown—perhaps merely a variety of *C. mexicana*, with a more persistent tomentum on the petioles; leaves, 4 to 5 ft. long, stout petiole, and rachis prickly; leaflets in about thirty nearly opposite pairs, 6 in. to 10 in. long by 1 in. or less broad.

A comparison of these descriptions would lead one to suppose that the plants described under the last names barely rank as distinct names, much less as species.

C. brevifrons is the same as *C. mexicana*, *C. boliviana* is *Zamia boliviana*, and *C. muricata* is *Z. muricata*. W. B. H.

STOVE PLANTS IN WINTER:

COMMON ERRORS IN THEIR CULTURE.

THE temperature that stove plants will bear and require, if they are to be made the most of by giving them as long a season for growth and flowering as is consistent with their health and well-being, is a subject upon which very different views are held. The injunction, a thousand and one times given, not to raise the temperature of the stove until the days get long, and to keep a low night temperature, has been well-nigh repeated until it has become an article of faith in gardening practice, and the individual who suggests anything opposed to this is looked upon as an innovator of unsound practice, that will quickly exhaust the plants. Yet those who hold such views very likely have never given a thought as to the night temperature that many of our stove plants are subject to in their native countries, even during the coolest season, neither considered the short season of rest they there undergo. On this latter point some allowance must be made for the shorter days we have in this part of the world in winter; yet I am convinced by repeated trials over a long period that the reason so many fail, or only partially succeed, with many of the best stove plants, is on account of the much too low temperature they are kept in during the winter, still further aggravated by their being kept dormant for much too long a period. The teaching that stove plants should not be excited into growth until the sun has got much power is so plausible, that many take it for granted and act accordingly, without ever attempting to prove it one way or the other by practice. It must be borne in mind I am not speaking of plants that only require, and which do the best in, an intermediate temperature, but of plants from the hottest parts of the world; and of these I say that by far the greater number are rested too long in winter, and during that time kept in too low a temperature. But when plants are started early, whilst the days are short, they must be grown in thoroughly good light houses, with the larger specimens that occupy the centre of the house elevated so as to all but touch the roof glass. The all-importance of light in the fullest measure we can give it, for flowering plants that are subject to a high temperature, has not yet been fully realised by many growers, possibly through the necessity for shading many of them from the direct rays of the sun when it is powerful. But we must not forget that it is a very different thing to simply shade a

plant from the burning influence of the sun, and to place it continuously where it will not receive sufficient light—a condition inseparable from plants when they are plunged in bottom-heat in the centre bed of a stove in houses of the ordinary construction; or when placed, as too often seen during the growing season, in a position where effective arrangement was more considered than their well-being. This is ever the case when placed so as to be below the eye. The same effects are inevitable when roof climbers are grown over the general occupants of the stove. Where the plants are of necessity subject to any of the above adverse conditions as to light, then of course it is better not to excite them too early by subjecting them to a temperature that will force them into rapid growth before the days are long. To the fact of flowering stove plants not being grown to produce fruit, and their existing in some sort of condition when they do not receive the full volume of light they so much need, may be attributed the apparent too general forgetfulness of their wants in this matter. What sort of success might the individual expect who, when starting his Vines in November for an early crop, kept them with their heads 4 ft. or 5 ft. away from the glass, with the evil still further aggravated by some kind of climbing plants grown at intervals above them, in the way common with stove plants? Yet flowering subjects require the greatest possible amount of light we can give them, just as do the Vines under the conditions I have named. When this is fully realised, we shall hear less of the advice to treat stove plants in a way that forces them into an unnaturally protracted rest, extending over four or five months of the year, and from the effects of which it takes them half the growing season to recover. For stove plants 65° in the night and 70° in the day, during the shortest days of winter, is the temperature most suitable to their requirements; and five weeks at the end of the year and five at the commencement—ten in all—is quite as long as it is either necessary or advisable to keep them at rest. As soon as we get fairly into February the heat may be increased two or three degrees, gradually rising it still higher as the days lengthen. During the time of the lowest temperature all deciduous plants, or such as are nearly so, should have the soil kept dry, without being in a condition absolutely devoid of moisture, or such as would cause the bark to shrivel. This completes the ripening process, and induces the cessation from growth also requisite. Plants so managed have their buds plump and round, ready to burst into strong, sturdy growth as soon as water is freely given; whereas those that are forced to rest by being chilled in an unnaturally low temperature are not in a condition to start freely. With many plants that are so rested it turns out to be their last rest, the life being starved out of them. The dry condition of the soil during the dormant season so necessary for deciduous plants, of which the *Allamandas* and *Bougainvilleas* are examples, must not be attempted with such as are evergreen, as for instance, the *Xorass* and *Gardenias*. These are very often injured by not receiving enough water at the roots in the winter, as also by keeping the atmosphere much too dry—a condition that is mischievous even to the deciduous plants, and totally unnecessary for them when their roots are kept dry enough.

The conclusions I have arrived at from this subject are based on experience. Numbers of the best and finest stove plants I ever grew were subject for nearly a score of years to a temperature, through the winter, of never less than 65° to 70° , except on the occasion of severe frost, and as near the higher figure as it was possible to keep them. Some plants were never during that time quite at rest, simply alternating betwixt active growth in the summer and slower growth in the winter. Yet the treatment they were thus long subjected to did not produce the slightest symptoms of wearing out; on the contrary, the oldest plants were as strong and vigorous as they were the first season they were grown. *Ixora coccinea* (the king of stove plants) I have cut freely back the first week in September, and have had the same plant in the middle of May bearing a hundred heads of flower, over a score of which were from $6\frac{1}{2}$ to 7 in. in diameter, measuring a wire passed through the centre of the flowers; many of the shoots were over 5 ft. in length, proportionately strong, with leaves almost as big as a common Laurel. Such growth as this was not produced by

starving the plants through the winter in a low temperature, but the opposite; they were never plunged in bottom-heat, but always kept elevated within an inch or two of the glass in a good house, where they got every ray of light possible, lowering them gradually as the shoots extended.

T. BAINES.

Imantophyllum miniatum as a House Plant.—The dark green, leathery foliage, and bright orange-coloured flowers of this plant, thrown up in large trusses, render it a very conspicuous and valuable plant for indoor decoration. I lately saw a plant in a 1-ft. pot with several immense heads of bloom upon it—one of which was fully 18 in. across, at the least. It had, when I saw it, been for some time in the front hall of the mansion, and was still in perfection, and much admired by visitors. The plant is common now, and the deep orange-coloured variety is the best.—J. S.

New Guinea Plants.—Under the title of "Papuan Plants," Dr. Mueller, of Melbourne, has published a first instalment of notes on New Guinea plants, collected by J. Reedy, who was sent thither by Sir W. Macarthur. Almost nothing new is here recorded, and certainly nothing that might not have been expected to occur; but Dr. Beccari, whose magnificent Bornean collections have enriched so many herbaria, is (according to the "Academy") collecting in New Guinea, and will doubtless add much to our knowledge of the flora of that interesting region.

Creepers for a Conservatory.—I have just erected a conservatory about 40 ft. by 20 ft., and am anxious to plant some creepers in it; they will require to grow some 8 ft. or 9 ft. before they reach the first iron brackets. It is intended to plant under the stages, and good borders are made. It would be desirable to have some ever-greens among them; would the following be a wise collection to try:—*Abutilon striatum*, *Bignonia grandiflora*, *Cobaea scandens variegata*, *Lapageria rosea*, *Passiflora* (two or three sorts), *Taesonia*, *Van Volxemi*, *Plumbago capensis*, *Cissus discolor*, *Hoya*, *Solanum jasminoides*, *Thunbergia laurifolia*, and some varieties of *Clematis*?—*Non*. [We should omit the *Abutilon*, *Cissus*, *Hoya*, and *Thunbergia*. *Clematis indivisa lobata* is the loveliest spring flowering greenhouse climber we have ever seen. *Fuchsias* are very beautifully treated as climbers].

Hardiness of the Camellia.—Like many other Japanese plants, the Camellia withstands our winters in the open, and considerable misconception exists as to its hardiness. We have four large plants of it here growing out-of-doors; one is a fine example of *C. variegata*, which last year produced 960 blossoms. We commenced cutting flowers from it on the 4th of October, and it continued blooming up to the 5th of May, and now (March 9) there are upwards of 200 blooms on it ready for cutting. The other is the old Double White, also a fine specimen, which produces some magnificent flowers. One planted in a border, exposed to all weathers and never protected, flowers abundantly. These Camellias have been exposed on several occasions to a temperature as low as zero, and yet are uninjured. When Camellias are planted out of doors, it is essentially necessary for them to have thoroughly good drainage.—E. M. DAVIES.

Agapanthus umbellatus as a Greenhouse and Indoor Plant.—This plant is amongst the most useful and most easily cultivated greenhouse plants we possess. It may be grown as a large or small specimen, and is exceedingly desirable for rooms, and very showy. The *Agapanthus* (African Lily) is a handsome greenhouse perennial, and a sure bloomer, and throws its large heads of delicate blue lily-like flowers well above the foliage. In the south of England and Ireland it is often grown as a hardy plant, but even where this is the case, well-grown specimens in pots will be found useful. A good plant in a 12-in. pot, with six or eight heads of bloom upon it, is one of the handsomest subjects for a single vase that can be employed, and we always think it looks best in a room. It should be grown in a cool greenhouse, and in a good light. We have recently potted our plants in good strong loam, sand, and leaf-mould, ramming the soil middling firm. They will have room and light and air, and when they come into flower during the summer they should be used exclusively for single vase work in the windows, passages, or front halls; for, being very hardy, the plant stands dry and draughty situations better than many others.—J. S.

Sash-lines for Forcing-houses.—The necessary amount of moisture in the atmosphere of forcing-houses soon rots ordinarily made sash-lines. The best that I have yet met with are those made of White Manila, which is not only as strong as wire rope but resists the effects of damp better than almost any kind of material used for the purpose.—J. GROOM, *Yentham*.

LANDSCAPE GARDENING.

MR. F. L. OLMPSTED, the well-known designer of the Central Park, New York, has an article on this subject in the new edition of Appleton's "Cyclopædia," from which we give the following extract:—

There are those who will question the propriety of regarding the production of the poetic beauty of natural landscape as the end of landscape gardening, on the ground that the very term "natural beauty" means beauty not of man's design, and that the best result of all man's labour will be but a poor counterfeit, in which it is vain to look for the poetry of Nature. Much has been written to this effect: with what truth to the nature of man it will be well cautiously to consider. It is to be remembered, with reference to landscape effect, that Nature acts both happily and unhappily. A man may take measures to secure the happy action and to guard against the unhappy action in this respect with no more effrontery than with respect to the production of food, or protection from lightning, storm, frost, or malaria. He need not wait for the slow and uncertain process by which, in Nature, a certain position would be adapted for a certain tree. He may make the soil fertile at once. He need not take the chance that a certain thick growth of saplings will be so thinned by the operation of what are called natural causes that a few of them may yet have a chance to become vigorous, long-lived, umbrageous trees, knowing how much more valuable a very few of these will be in the situation, with the adjoining turf holding green under their canopy, than the thousands that for long years may otherwise occupy it, struggling with one another and barring out the light which is the life of all beneath them, he may make sure of what is best with axe and bill-hook. The ultimate result is not less natural or beautiful when he has done so than it would have been if, at the same time, the same trees had been eaten out by worms or taken away, as trees sometimes are, by an epidemic disease. On the other hand, there are several considerations, neglect of which is apt to cause too much to be asked of landscape gardening, and sometimes perhaps too much to be professed and attempted. The common comparison of the work of a landscape gardener with that of a landscape painter, for example, easily becomes a very unjust one. The artist in landscape gardening can never have, like the landscape painter, a clean canvas to work upon. Always there will be conditions of local topography, soil, and climate by which his operations must be limited. He cannot, whenever it suits him, introduce the ocean or a snow-capped mountain into his background. He cannot illuminate his picture with constant sunshine nor soften it by a perpetual Indian summer. Commonly, he is allowed only to modify the elements of scenery, or perhaps to bring about unity and distinctness of expression and suggestion in a locality where elements of beautiful landscape already abound, but are partly obscured or seen in awkward, confusing, and contradicting associations. This is especially likely to be the case in undulating and partially wooded localities, such as are often chosen for rural homes. Again, the artist in landscape gardening cannot determine precisely the form and colour of the details of his work, because each species of plant will grow up with features which cannot be exactly foreknown in its seed or sapling condition. Thus, he can see his designed and imaginary landscape only as one may see an existing and tangible landscape with half-closed eyes, its finer details not being wholly lost, yet nowhere perfectly definable. Still, again, it is to be remembered that works in landscape gardening have, as a general rule, to be seen from many points of view. The trees which form the background, still oftener those which form the middle distance, of one view must be in the foreground of another. Thus, the working out of one motive must be limited by the necessities of the working out of others on the same ground, and to a greater or less degree of the same materials. Finally, the conditions of health and convenience in connection with a dwelling are incompatible with various forms of captivating landscape beauty. A house may be placed in a lovely situation, therefore, and the end of long and costly labours of improvement about it prove comparatively dull, formal, and uninteresting. What is lost is a part of the price of health and convenience of dwelling. The landscape gardener may have made the best of the case under the conditions prescribed to him. It has been said that landscapes of a particular type associate naturally and agreeably with certain events. It is to be added that the merit of landscape gardening consists largely in the degree in which their designer has been inspired by a spirit congenial to elements of locality and occasion, which are not, strictly speaking, gardening elements. The grounds for an ordinary modest home, for instance, may desirably be designed to give the house, gardens, and offices an aspect of retirement and seclusion, as if those had nestled cozily down together among the trees in escape from the outside world. The grounds of a great public building—a monument of architecture—will, on the other hand, be desirably as large in scale, as open, simple, and broad in spaces of turf and masses of foliage, as con-

venience of approach will allow, and every tree arranged in subordination to, and support of, the building. The grounds of a church and of an inn, of a cottage and of an arsenal, of a burying-place and of a place of amusement, will thus differ, in each case correspondingly to their primary purpose. Realising this, it will be recognised that the choice of the site, of the elevation, aspect, entrances, and outlooks of a building for no purpose can be judiciously determined except in connection with a study of the leading features of a plan, of its approaches, and grounds. Also, that in the designing of roads, walks, lakes, and bridges, of the methods of dealing with various natural circumstances, as standing wood, rocks, and water; in a determination of what is possible and desirable in respect to drainage, water supply, distant prospects to be opened or shut out, the avoidance of malaria and other evils—all these and many other duties are necessarily intimately associated with those of gardening (or the cultivation of plants) with a view to landscape effects.

RUSH CARPETS.

BEFORE the era of carpets, it was customary to strew Rushes, hay and leaves, sometimes mingled with sweet smelling Herbs, over the floors of the rooms; which ordinarily were allowed to remain several days or weeks, and become the receptacle of the *débris* of meals, and dust, and dirt, from which arose an unwholesome effluvia. It was thought to be a piece of unnecessary luxury on the part of Wolsey, when he wisely caused the Rushes of Hampton Court to be changed every day. We have frequent allusions to them in the writings of the period. Froissart says, "The Count de St. Foix went to his chamber, which he found ready with boughs newly cut for perfume." Sir Thomas More (1483) describes Elizabeth, the widowed Queen of Edward IV., when in the sanctuary at Westminster, as "sitting alone amongst the Rushes in her grief and distress." Bradshaw in St. Werburg (1500) writes:—

"All Herbes and flowres fragrant, fayre and swete
Were strewed in halls, and layed under theyre fete."

The last monarch whose presence-chamber was so covered was Queen Elizabeth. Shakespeare, in "Romeo and Juliet," act i., scene 4, writes:—

Let wantons, light of heart,
Tickle the senseless Rushes with their feet."

And in "Katherine and Petruchio," act iv., scene 1, it is asked—

"Are the Rushes strewed?"

There was a person called a Rush-strewer attached to many houses.

The Formation of Coal.—Mr. E. A. Wunsch, in his annual address to the Geological Society of Glasgow, referring to the evidence showing the immense time required to produce a seam of coal, drew attention strongly to the conditions which he had examined in the Isle of Arran. There he "found numerous cylinders of trees completely flattened of course, lying across each other at various angles, with their bark, compressed into less thickness than common pasteboard, and the carbonaceous matters reduced to graphite, so that from 3 in. to 4 in. in thickness of this impure coal contained probably twenty generations of trees overlying each other. Now if we allow thirty years only for the life of each tree, we have 600 years for the formation of 4 in. of impure coal, or 1800 years for the formation of 1 ft. of coal."

The Cause of Landslips.—The fall of hill masses is a phenomenon not uncommon in Switzerland. The nature of such catastrophes is investigated in a small work recently published by Dr. Britzer. He distinguishes in every such fall three regions—the place of origin; the cause of the rushing mass, and the region of deposition. Most of the phenomena are due to the softening of impermeable marl, clay, or clayey rocks, in whose layers the water stagnates. The mass is gradually loosened and loses its hold. Fissures first arise, as certain pieces of the surface break away before others. When the last attachments are sundered the mass slides down (like a ship from the stocks) on the slippery underlayer, or tumbles over, breaking into pieces. There are frequently, however, falls of greatly inclined masses, without any softened layer being present. The masses have been saturated with water, which has increased their weight, and they glide down over their solid, rocky foundation, simply in consequence of dissolution and increased weight. Further causes are earthquakes and loosening of the rocks through frost. The phenomena still, however, present many problems to the geologist.

Raffia—In many of our seed stores Raffia is introduced in competition with Linden bark for young plants. It is not quite so low in price, but is sometimes thought to go further. It is according to the "Gardeners' Monthly," simply the split leaves of a Palm of Madagascar—*Sargus Raffia*.

PLATE XIV.

THE BEAKED PHALÆNOPSIS.

(PHALÆNOPSIS PHALÆNOPSIS.)

By F. W. BURBIDGE.

The different species belonging to this genus have long been considered to be among the most beautiful of all Orchids; and, as no collection of the warmer-growing kinds is complete without them, a few remarks on their culture may prove useful. These beautiful plants, with one or two exceptions, come from the hottest and most humid portions of the earth's surface—viz., Java, Borneo, Sumatra, and other islands of the Malay Archipelago; while a few are found on the Continent of India itself, their principal habitats being Moulmein, Rangoon, and the Eastern Himalaya; one or two are also natives of the Philippine Isles. In cultivation, they require the warm humid temperature of a plant-stove, or East Indian house; for, of all Orchids, these are the least likely to adapt themselves to what is generally termed "cool treatment." P. Schilleriana, however, perhaps the hardiest of the whole group, grows moderately well in a warm Cattleya-house, or cool plant-stove, where the temperature does not descend below 50° during winter. But it is best to grow all the species together in a warm corner, where the winter temperature is regular, and never below 60°. When well grown, few other Orchids rival these in graceful beauty; they are not only profuse bloomers, but their delicate white or rosy-tinted flowers last in perfection for many successive weeks; indeed, it is nothing uncommon for P. amabilis and P. grandiflora to be in flower for six or eight months out of the twelve, while it is a rarity to find P. rosea except in bloom. Mr. Robert Warner has had over 1000 Phalænopsis flowers fully expanded at the same time in his collection at Chelmsford. Young plants, with only one or two leaves, frequently throw up flower-spikes, and, if allowed to flower, they often seriously injure themselves in so doing. It is best in practice to pinch off all flower-spikes as soon as they appear, until the plant has become thoroughly well established, for nothing tends so much to weaken their constitutional vigour as early flowering. Phalænopsis may be propagated by dividing plants that break from the base, and some plants do so very freely, especially if the leading growth becomes checked or injured in any way, while not unfrequently some of the species produce young plants adventitiously on their old flower-stems. P. amabilis, P. grandiflora, P. Schilleriana, but more especially P. Luddemanniana, frequently throw off young plants in the way just named. When these plants commence to emit roots, they can be fixed on small flat blocks or rafts of Teak or Acacia-wood, and left on the parent plants until established firmly in their new quarters, after which they can be severed from the plant and treated as separate individuals. During the summer months, a little fresh living Sphagnum Moss placed around the fleshy roots of plants on blocks is beneficial, as it preserves them from extremes of moisture and exposure to the sun. Small plants do best on blocks suspended in a close warm corner of the house, and near the light. As they increase in size, they can be partially plunged in well-drained pots, taking care, however, not to hamper the roots with too great a bulk of finely-divided compost, which is apt to settle down among the drainage and become sodden, in which case the roots embedded will speedily rot. In Orchid-houses, which are naturally dry, the roots of nearly all Epiphytal Orchids seem quite willing to enjoy the shade and moisture afforded by rough lumps of fibrous peat and fresh Sphagnum; but only supply them with a genial temperature, saturated pretty regularly with the soft vivifying humidity in which they luxuriate so vigorously in their native habitats, and the roots will soon creep out into the light and air, wrap themselves round pots, blocks, or anything that comes in their way, or even bind themselves together in bundles. If Phalænopsis are grown in pots—and we know that noble specimens are so grown—the compost used should consist of the best fibrous peat obtainable, carefully broken into lumps the size of pigeons' eggs, or larger, and mixed with an equal quantity of crocks and fresh living Sphagnum. The pots themselves should be thoroughly clean, and may be filled four-fifths of their heights with fresh crocks well washed, placing

THE BEAKED PHALENOPSIS. (P. LOWII)

a layer of small ones on the top, and a layer of good tough Moss above that, to prevent the smaller particles of the compost from washing down and choking the drainage below. Elevate the collar of the plant well above the rim of the pot, and gently embed the lower roots into the above compost, placing a layer of freshly-picked Moss over the whole, so as to form a rounded cone with the plant at its apex. Plants potted in this manner rarely fail to grow well, as the air has free access to the roots; and, unless this is the case, they soon go wrong, while it is almost impossible for them to be injured by any undue excess of water, as there is every facility for any superfluity of moisture to escape. The secret of Orchid-growing is genial humidity in the atmosphere, small pots well drained, fresh living Sphagnum on the surface of the compost, and an abundant supply of tepid water, and a regular temperature when making their growth. One of the best grown private collection of Phalaenopsids we have yet seen is that of Mr. Michaels, Cholmeley Park, Highgate, who grows them in a small lean-to house, of which our engraving represents a section. A week or two ago we here saw fifty or more plants of *P. amabilis*, *P. grandiflora*,

and *P. Schilleriana* in great beauty, the gorgeous wreaths of broad-petalled flowers hanging gracefully on every side. Mr. F. Newman, who cultivates Mr. Michaels' plants, thus describes his mode of treatment for Phalaenopsids:—"In March the house is kept comparatively dry and cool, but I give the plants sufficient moisture at the roots to enable them to sustain their burden of flowers. The average temperature by night is 58°; day temperature, if fine, 65°; if cold and frosty, 62°; but, as the season for growing advances, I increase the heat and moisture, and in the summer months (June, July, and August) the average temperature of the house by day is 85°, sometimes 90°, falling at night to 75°, keeping the plants saturated with an abundance of atmospheric moisture, or feeding by precipitation, never allowing the house to become dry. A little weak manure-water several times during the growing season will be found highly beneficial. When the house is closed for the night I occasionally sprinkle the paths with water impregnated with cow or fowl manure, being very careful not to give an over-dose, and I invariably find such treatment a great preventive in keeping down insects. Most of the plants (nearly 100 in all) are grown in baskets made of Teak-wood, with a few cracks and some good fresh Sphagnum.

Last year the glass was painted over with a light green colour, in addition to which I used a thin blind when the sun was bright." Some of the finest specimens of Phalaenopsis in this country are grown in pots. A superb example of *P. Schilleriana* in the collection of Mr. Milne, Yewfield House, Arbroath, is growing in a great tub, and bears nearly 200 flowers on a single spike! Mr. Rawson, of Mill Hill House, Halifax, has some remarkable specimens of *P. amabilis* and *P. grandiflora* with ten or twelve fine leaves each, and these are grown in common square wooden baskets, suspended near the roof of an ordinary span-roof plant-stove. On one plant of *P. grandiflora* I saw eighteen flowers on the tip of a branched spike all open at the same time, and these were nearly 4 in. across, and of good substance. It is seldom one sees nine fully-expanded flowers on each side of the tip end of a single spike, as above described; although we occasionally come across a plant bearing fifty or sixty flowers open at once on several great branched spikes. Mr. Turner, of Leicester, grows his noble plants of Phalaenopsis on semicircular rafts made of Teak, and surfaced with fresh Sphagnum only; and when I saw them, some months ago, they were perfect in health and vigour. Messrs. Veitch & Sons, of Chelsea, have a noble plant of *P. Schilleriana* growing on a Teak-wood raft, partially plunged in a pot of fresh open compost, as above described. This specimen has ten or more fine speckled leaves in that state of fresh vigorous health so pleasing to the true plant-grower, and it is now bearing a noble spike of nearly a hundred flowers. I mention these diverse methods of treatment in order to show that there are several ways of growing Phalaenopsis in perfection. They grow best, as a rule, in a warm sheltered corner, not far from the glass; and the beginner who would be successful should try them in different positions in his house until he is perfectly satisfied as to the position in which they thrive best. Fortunately, some species of Phalaenopsis have been imported in quantity and in excellent condition; their price is, therefore, now moderate. Imported plants generally come on long blocks, and, occasionally, a part of the branch on which they grew in their native habitats is lopped off and nailed to the side of the case with the plant *in situ*. If these plants arrive during dull weather or in the autumn, it is best not to disturb them until the following spring, when they may be removed, and either placed on other blocks or potted as above recommended. When well-bloomed the plants are very ornamental from a decorative point of view or for exhibition purposes; while their waxy flowers are invaluable for cutting, either for bouquets, vase decoration, dinner-table ornaments, or for arrangement along with fresh green Ferns or other foliage in ladies' hair, especially as they last in perfection for a considerable time after being cut. The following descriptive list comprises all the species at present introduced to our gardens:

P. amabilis.—This is generally known as "the Queen of Orchids;" it has dark green foliage tinted with purple beneath, and its branched flower-spikes are borne very freely, its individual blooms lasting a month, or even longer, in perfection. The flowers vary from 2½ to 3½ in. across, and are of pearly whiteness, except the lateral or side lobes of the lip, which are streaked with rosy-crimson. Good specimens of this plant have from eight to fourteen leaves, and bear spikes from 2 to 4 ft. long. When well grown it is one of the best of Phalaenopsids, and its snowy blossoms are useful for cutting. Blume, who was one of the first to figure and draw attention to this noble plant, speaks of a variety having purplish backs to the petals; and Mr. W. Bull recently exhibited a fine form of it under the name of *P. erubescens*, the flowers of which are large and of good shape and substance, while the central lobe of the lip is conspicuously varied with brown on a yellow ground. *P. casta*, recently imported by Mr. Low, is a form with indications of grey marbling on the dark green leaves, and the flowers are delicately flushed with rosy lilac. It is a native of Manila. This plant is the *P. aphrodite* of Professor Reichenbach, who points out that the *P. grandiflora* of Lindley is identical with the *P. amabilis* of Blume. Good figures of the typical plants may be seen in the "Botanical Register," vol. 2, t. 34, and in the "Botanical Magazine," t. 4287.

P. amethystina (*P. Wightii*).—This pretty little plant is rather rare in collections, and is not so showy as some of the other species; still it is well worth growing, and lasts a long time in bloom. It has deep green oblong foliage, with wavy margins, and bears short-branched spikes, which vary from 3 to 12 in. in length. The flowers are little more than ½ in. across, the sepals and petals being white, dotted with rosy-purple at the base. The lip is of a deep amethyst.

purple tint, tipped with white, and having two slender horns at its base. It is a native of the Sunda Isles, and has flowered with Dr. Ainsworth, Mr. C. Stead, and Mr. Day, of Tottenham. This is a very variable plant, and two or three of its forms are described as species by Reichenbach. P. Hebe, figured in the "Xenia Orchidacea" is a small form, the emarginate central lobe of the lip of which is terminated by two rounded lobes, instead of sharp points. P. Wightii is another form which differs but slightly from the type, and one which has creamy-white flowers. P. deliciosa of the last-named author also appears to be a form of this pretty little plant. In October of last year I saw four or five examples of this neat-habited plant flowering in the Chelsea Nursery, and the different forms of it vary much in colour, the violet colouring of the lip in some individuals being very brilliant. When closely examined it is a little gem, its pearly-white, rose-dotted sepals and petals contrasting well with the violet or amethystine-tinted lip. Like P. rosea, this species has rarely more than three or four flowers expanded at the same time, but as each spike bears from thirty to fifty flowers, it follows that the plant remains in flower several weeks, or even months, together. It well deserves a place in all collections in which modest but beautiful species are appreciated.

P. grandiflora.—This is now one of the commonest of all the species, and may be bought for shillings where guineas were formerly demanded for it. It is one of the best and most profuse flowering of Phalaenopsis, and grows well either on a block or in a pot near the light. There are numerous varieties of it in cultivation, all more or less distinct, the Bornean plants being for the most part the best. The sepals and petals, like those of P. amabilis, are pure white, the lateral lobes of the lip being tinted with golden-yellow; and, in the best forms, the tails at the tip of the lip are yellow, spotted with crimson. The best variety is known as P. grandiflora aurea, or Ruckerli, and has the side lobes of the lip deeply stained with golden-yellow, while the petals are very broad and more rounded than is generally the case. The varieties of this grand Orchid not only vary in the size of their flowers, but also in the length and breadth of their light green foliage. Mr. Williams, of Holloway, has a fine plant of it with ten or twelve large leaves borne on a stem nearly 6 in. high, and this is now producing two very strong spikes. Mr. C. Stead, of Balldon, near Leeds, has a fine plant of the narrow-leaved variety, with fourteen or fifteen leaves 10 to 15 in. long, and only 2 to 2½ in. broad. This is a Bornean plant, and flowers very freely, bearing large flowers of good substance. Native of Borneo and Java. I saw a fine form of this plant in Mr. Heriot's collection the other day, and Mr. Bull once showed me a singular little variety, the flowers of which were certainly not larger than a shilling, although in every way perfectly developed. P. grandiflora fuscata is a rare form in which the central lobe of the lip is suffused or veined with dark brown at the base on a golden-yellow ground, apparently analogous to that variety of P. amabilis previously alluded to as P. erubescens. One of the earliest and best figures of this plant is that in Blaine's "Rumphia," t. 194-199.

P. intermedia (P. Lobbii).—This plant is very beautiful, having white flowers shaded with rose, about the size of those borne by a small-flowered P. Schilleriana, the lip being of a still deeper rosy-tint. In habit it resembles its allies, and it also does well under the same treatment. It is a native of Manila. There is a fine variety of this species known as P. intermedia Portei, a native of the Philippine Islands, only a solitary plant having been found in flower by M. Porte, its discoverer. Its foliage is light green above, and purple below, being 8 in. or 10 in. in length. It is one of the rarest of all known Orchids. The flowers are 2 in. across; sepals and petals white, suffused with rose; the lip being of a dark rosy-purple tint. This plant cannot be distinguished from P. amabilis when growing, and is supposed to be a natural hybrid between P. amabilis and P. rosea. The typical plant, according to the sketch in Lindley's "Herbarium," has white sepals and petals dotted with rose at the base, the lip being of an amethyst-purple, which, running into the yellow ground colour at the base of the middle lobe, produces a rich orange-tint similar to that observable in P. rosea. The still more beautiful form P. Portei, according to the plate in Warner's "Select Orchids," has the extreme base of both sepals and petals suffused with rosy lilac, but in the splendid specimen now flowering in Lord Londesborough's collection, they are pure white, without even the rosy dots shown in Lindley's sketch. One of the finest of all these varieties of P. intermedia, and certainly the rarest, is P. Vetchii, which has the flower of P. intermedia, but both sepals and petals are suffused with bright rosy lilac, and the lip is still more brilliant, and very delicately veined. The leaves, too, differ from those of all the other forms of P. intermedia in having faint greyish marbling in the way of P. Schilleriana, and the apex of the central lobe of the lip has two sharp teeth, something like the tail of a fish, these being perfectly straight, not tendrill-like, as in P. intermedia properly so called, nor

arched as in P. Schilleriana. This plant well deserves the specific honours given to it by Professor Reichenbach, and is believed to be a natural hybrid between P. rosea and P. Schilleriana. The last novelty in this group is P. intermedia var. Brymeriana, which has just bloomed in Mr. Brymer's collection, and which is said to differ from all its allies in having the lateral lobes of the lip white, delicately edged with rosy-purple. This is the only form I have not seen, but Mr. Harry Veitch informs me that it is a very desirable species, and quite distinct.

P. cornu-cervi (Stag's-horn Phalaenopsis).—This is a peculiar plant, somewhat resembling P. Luddemanniana in habit, but bearing shorter flattened spikes of yellow flowers, blotched transversely with brown. The flattened flower-spike is a peculiar feature; hence its specific name. It grows well treated like its congeners, and is worth cultivation for the sake of variety. It was discovered by Mr. Lobb, and is also known as Polychilos cornu-cervi. Native of Moulmein.

P. fuscata (Brownish Phalaenopsis).—This rare plant, which was introduced a year or two ago by Mr. Bull, is very similar to the last-named plant; it has yellow flowers strongly marked with brown, but the lateral sepals are shorter, and the flower-spike is cylindrical, not flattened as in P. cornu-cervi. It is not a showy plant, and only deserves a place in collections as a distinct species.

P. Lowii (Beaked Phalaenopsis).—This is a pretty little species that grows best on a block suspended near the light. It bears eight to ten flowered spikes, about 1 ft. high; the flowers themselves being of a rosy-lilac tint. The front of the column is curiously prolonged, like the beak of a bird. In its native habitat in Moulmein, it grows on limestone, fully exposed to the sun, and loses its foliage every year during the hot and dry season; but, here at home, the plant frequently retains its foliage through the winter months. Its leaves are about an inch wide, and 2 or 3 in. long, of a dark green colour, speckled with purple. Mr. Bockett, The Firs, Muswell Hill, has a fine plant of this species, with leaves nearly 4 in. long and 2 in. wide; and it also does well in Lord Londesborough's collection. It should be kept rather dry during winter, and fully exposed to the light, or it is apt to lose its leaves. This plant was discovered by Mr. T. Lobb, and also by the Rev. C. H. Parish, who sent specimens and sketches of it to Sir W. Hooker, under the name of P. Proscoides, remarking that the column and its beaked termination resembled an elephant's head and trunk. It appears to have been first flowered by Mr. Walter Beck, of Isleworth, and well deserves the most careful culture. It is figured in the "Botanical Magazine," t. 5561, and a good figure is also given in Warner's "Select Orchids."

P. Luddemanniana.—This is one of the most beautiful and distinct of all the Phalaenopsis, having leaves of a bright shining green, and about 6 or 8 in. long. The flower-spikes are very variable in length, but generally about 18 in. or 2 ft.; the flowers being of a soft amethyst-purple tint—in the best varieties blotched with brown—the narrow lip being set with a row of white hairs down its centre. There is a poor variety of this plant, having pale yellow flowers barred with brown, called P. Luddemanniana ochracea, but the amethyst-tinted varieties are best. This plant grows very freely in a pot, and very often produces young plants on its flower-stems. There is a fine plant of the best variety in Mr. Hadwen's collection at Fairfield, near Manchester, which seldom fails to bear two or three plants every year. P. Luddemanniana pulchra is one of the prettiest forms of this plant; the sepals and petals being of a brilliant amethyst or violet-purple tint, with scarcely any traces of the transverse bars or marking which characterise the other forms. Several large-flowered and richly-coloured specimens are now blooming in Mr. Geo. Heriot's collection at Highgate, and the rare pallid form, P. ochracea, bloomed in the Chelsea Nursery last year. One distinct variety of it, having very narrow dark brown bars or lines on the sepals and petals, has been named by Professor Reichenbach P. delicata. All the forms of this plant are good, and vigorous specimens of it are nearly always in bloom. A good coloured figure of it is given in the "Botanical Magazine," t. 5523.

P. rosea (P. equestris).—This is a pretty plant, similar in habit to the last-named, and worth growing in every collection for its free-blooming qualities. Its flower-spikes are of a deep purple colour, and keep on producing flowers for months in succession. The flowers are of a soft rosy-lilac colour, scarcely more than ½ in. across, but the want of size is compensated for by the numbers produced. There is a good plant in Mr. B. S. Williams's collection, and another at Kew, and we have recently seen a very brilliant form of it blooming in Mr. Heriot's collection. It is a robust-growing plant, and comes from Manila.

P. Parishii.—This is the smallest, and, at the same time, one of the prettiest of all the Phalaenopsis. Its leaves are about 2 in. long, and of a grey or glaucous tint. The small violet and white flowers are borne five or seven together on spikes about the same

length as the leaves. Although not so showy as the larger-flowered kinds, it is, nevertheless, well worth cultivation. This plant is a native of Burmah, and its thick, greyish, aerial roots throw out short fibres or rootlets, much in the way of *P. Mannii*. These rootlets enable the plants to adhere firmly to rocks, or the wooden basket in which it is placed, much in the same way as the common Ivy clings to a moist wall or the bark of a tree. The variety figured in the "Botanical Magazine" has a brilliant carmine lip, but in all we have seen this organ is of a dull purple. A pale form of it is figured in the "Refugium Botanicum."

P. Schilleriana.—One of the best of all Orchids with variegated foliage, bearing great branching spikes 3 or 4 ft. high, with from 100 to 200 rosy flowers fully expanded at the same time. Few of the other species rival this when well grown, and the plant is hardier in constitution than any of the others at present introduced. The leaves are of a deep green colour, variously mottled and marbled with silvery-grey. The sepals and petals are of a rosy-lilac colour, the lip being tinted with rose and spotted at the base with warm crimson-brown. It does best in a pot, although small plants luxuriate well enough on flat blocks. It is a native of Manila. A very soft, rosy-coloured large-flowered form of this species was exhibited at South Kensington by Sir Henry Peck, of Wimbledon House, a week or two ago, and a specimen of it, grown by Mr. Cross, of Melchet Court, bore over 300 flowers on three large-branched spikes. When well grown, there are but few winter-blooming Orchids which rival this in graceful beauty and profusion of bloom. Like *P. grandiflora*, it sports into numerous forms; but as Phalanopsis, like nearly all other Orchids, are reproduced or increased in their native habitats from self-sown and often cross-fertilised seeds, this variation in size, form, colour, and marking, is to be expected, and here, doubtless, we have a good explanation of that Protean variability amongst Orchids which so confused the earlier botanists, to whom their cross-breeding tendencies and habits were unknown.

P. Sumatrana.—The foliage of this plant resembles that of *P. Luddemanniana*, and it grows well under the same treatment as recommended for the last-named species. The flowers are white, barred with pale rosy-crimson, and about 2 in. or 2½ in. across. It flowered with J. Day, Esq., of Tottenham, in 1865, but is still extremely rare in collections, although well worth growing. As implied by its specific name, it comes from the Island of Sumatra. This plant, which first flowered in continental gardens, is sometimes known as *P. zebirina*, and the *P. violacea* of Siebold's "Pl. Jard." 1861, 10, is nearly related to it. Lieut.-Colonel Charlton, of Farm Hill, Bradden, has seen in India a scarlet-flowered species, and has several times tried to introduce it, but has failed. Prof. Reichenbach has described a species under the name of *P. Esmeralda*, which is said to be near *P. rosea* (*P. equestris*), but has more showy flowers. Of this I can hear nothing, nor of Mr. Low's panther-striped Phalanopsis (*P. Pantherina*). Any tidings of these species, or references to drawings or specimens of them would indeed be acceptable.

P. Mannii (Gustave Mann's Phalanopsis).—This has been long known in the shape of dried specimens, and quite recently I had an opportunity of seeing two vigorous little specimens of it blooming in Mr. Heriot's collection at Highgate. Its leaves are rather thin, lance-shaped, from 6 in. to 8 in. long by 1½ in. to 2 in. broad, of a bright glossy green colour, and much spotted towards the base with dark purple. Its flower-spikes are five or six-flowered in cultivation, although native specimens of it show twenty or more blooms. Its flowers measure about 2 in. across, the sepals and petals being oblong slightly curved, with very singularly-pointed tips. The ground colour is yellow blotched with reddish-brown, the whole shining as if varnished. The lip is very curious, being three-lobed, the lateral divisions white and erect, of wax-like consistence streaked with purple, and between them at the base rises a purple horn and two slender hair-like filaments. The central lobe is lunate (with a central papillose ridge), the margins fringed with short yellowish hairs. It is not very showy, but is far prettier and more graceful than its allies *P. cornu-cervi* and *P. fuscata*.

P. casta (Rosy-flushed Phalanopsis).—This interesting plant was recently found in a batch of Orchids sent to Mr. Low from the Philippines, and also the equally interesting *P. leucorrhoda*, both evidently natural hybrids between *P. amabilis* and *P. Schilleriana*. The leaf is that of a rather long-leaved *P. amabilis*, but on some of the forms there are slight traces of grey marbling. Its flowers are also those of *P. amabilis* in shape and substance, but the bases of the petals and sepals are suffused with rosy-lilac. This flushing of delicate colour on petals of snowy whiteness is very beautiful, and whether it be species, hybrid, or semial variety, it well deserves a place in every general collection of these showy plants.

P. leucorrhoda (Low's Hybrid Phalanopsis).—This is another of Mr. Low's recent importations, a plant of which was first exhibited

by Mr. Ball, of Chelsea. Its leaves are like those of a pale marked *P. Schilleriana*, and its flowers closely resemble the blossoms of that species in size and colour, but in the shape of the petals and lip they bear a stronger resemblance to those of *P. amabilis* which, supposing these forms to be natural hybrids, must be one of the parents, *P. Schilleriana* evidently being the other. There are scarcely two forms of this plant alike in leaf and flower; indeed some have leaves identical with those of the last-named species, while others have the foliage of *P. amabilis* with scarcely any indications of the grey marbling so characteristic of *P. Schilleriana*. The flowers also vary much in colour, from pure white, slightly flushed towards the base of the segments with lilac, to deep rosy-purple. All the forms of it are, however, very beautiful, and well deserve culture, although at present both this and its ally, *P. casta*, are very rare. Although Lindley separated *P. amabilis* from *P. grandiflora* on account of the different colour of the leaves, general shape of the flower, and the crimson-purple streaks on the side lobes of the lip, yet there can be no doubt that they are very nearly related, and now we find *P. Schilleriana* distinct, as it is both in leafage and flower united to *P. amabilis* by the natural hybrids, *P. casta* and *P. leucorrhoda*. It may be said that we have no evidence to prove the latter as natural hybrids and not natural species or semial forms, but the latter are hybrids and not natural species or semial forms, but the great fact remains that in structural details, and general appearance, they are exactly intermediate, and the hybridist is quite as likely to be right in assuming them to be hybrids as the botanist is in describing them as species. With cultivators, however, the important fact is that these seemingly intermediate forms are all very beautiful and highly desirable as choice decorative plants.

Dearly Bought.—Mr. Frank Buckland, writing on the subject of sleeplessness, says:—"Everybody knows the taste of Onions. This is due to a peculiar essential oil contained in this most valuable and healthy root. This oil has, I am sure, highly sporic powers. In my own case it never fails. If I am much pressed with work, and feel I shall not sleep, I eat two or three small Onions, and the effect is magical."

Congress of Nurserymen.—At a meeting of the nurserymen, florists, and seedsmen at Crystal Lake, Illinois, Jan. 26th, it was decided to hold a centennial meeting of all engaged in the trade, in the city of Chicago, on the second Wednesday of June, 1876. The objects of the meeting are—(1) relaxation from business; (2) the cultivation of personal acquaintance with others engaged in the trade; (3) exhibition of any new fruits, flowers, plants, or any manufactured articles, or implements used in the business, purchase or sale of surplus stock; and (4) to perfect better methods of culture, packing, and sale of stock.

How Electricity Splits Trees.—The theory that the splitting of the trunks of trees by lightning is the result of the sudden evaporation of the liquids contained within them, has received much confirmation from experiments made by Osborn Reynolds, who succeeded in splitting small sticks of wood by passing the electric sparks through them after they had been impregnated with water. He also burst some glass-tubes which were filled with water, although the same tubes when empty allowed the electric spark to jump through them without in the least disturbing them.

Plant Remedies for Tape-worm.—At the desire of the French Société Médicale des Hôpitaux M. Regnaud has recently procured exact information as to the consumption of ténifuges (or remedies for tape-worm) in the Parisian hospitals during the ten years 1864—1874. The remedies used in Paris are the flower-tops of Kousso, the seeds of Gourds, the bark of the root of the Pomegranate, and the root of the male Fern. A very considerable increase of consumption of all of these appear from the Table; and one may infer that the number of individuals attacked by ténia has increased during these years. From personal observations M. Regnaud was led to think that the quality of certain animal species, consumed in an exceptional manner, during the siege of Paris, played an important part in the unwonted transmission of entozoa parasites. Should this be so, there ought to be a marked difference between the mean annual prescription of ténifuges during the years preceding 1870, and that during the years after it. This he finds is the case. Thus the mean annual consumption before and after 1870, respectively, was, of Kousso, 3900 kil.; 9000 kil.; of Gourd seeds, 3005, 5311; of bark of Pomegranate root, 13,001, 14,025; of rhizome of male Fern, 5147, 12,000. The first and fourth, most in repute, have thus more than doubled.

Petroleum v. Garden Destroyers.—A French paper says that petroleum destroys all insects and banishes rats and mice. Water slightly impregnated with petroleum applied to plants infested with insects will, it is said, destroy the latter at once.

TREES AND SHRUBS.

DENDROPHILIA :

OR NOTES FOR PLANTERS, ESPECIALLY ON EXPOSED SEA-COASTS.

By SALMONICEPS.

(Continued from p. 230.)

Undergrowth.

WHEN old woods, which perhaps have been long neglected, receive the required thinning, they often look so bare that the owner is dissatisfied, and proceeds to fill them up with Spruce, Silver Fir, or other trees, which will be overtopped and smothered long before they come to any size, for it is astonishing how quickly even aged trees will spread when room is given. The boughs, which have all been thrust up to light and air, gradually lean outwards and burst out all over buds, and in a very few years the spaces between the stems will be filled with heavy foliage. There are only two trees which can be grown successfully under the shade and drip of old wood, namely, Yews and Hollies. These will make a beautiful undergrowth even in a very dense wood, provided it does not consist of Beech, or any kind of evergreen trees. These two beautiful trees should be largely planted, as they are always ready to fill gaps made by the wind, and no other trees known to the writer, except perhaps the Laburnum, thrive so vigorously under old wood. And this suggests one word to the owners of parks. Let no lodges, cottages, or human dwellings high or low be overhung by trees. It is a vital matter. No consideration of beauty or association should be allowed to endanger human health. That it is so endangered in too many instances from ignorance of the truth is unquestionable, for too often do we see park lodges picturesquely situated in the dense shade of old trees. No life can be vigorous in semi-darkness, so if the trees cannot be sacrificed, the cottage should be pulled down. Mr. Howard Barrett, in his book on "The Management of Childhood and Infancy in Health and Disease," quotes the following case in point:—"A French surgeon's attention was drawn to the mutilated condition of some large Mulberry trees, whose boughs had overshadowed a schoolroom in which several girls with chronic diseases were educated. On his inquiring why they had been cut, he was told that the deep shade produced by them had visibly aggravated the scrofulous disorders rife among the girls, and that a very favourable change in their condition had taken place since their exposure to free sunshine." We may believe that in a hot climate the old Mulberry trees formed the pleasantest feature in the house, as seen from the outside, yet nothing could have justified the owner in not sacrificing them under the circumstances. The principle contained in this example may be widely applied by most landowners, and should be carefully attended to and carried out.

Fencing.

It does not enter into the scope of these jottings to compare the relative cost of different modes of fencing plantations. The subject has been so fully entered into, not only in such comprehensive treatises as Brown's "Forester" and others, but from time to time in many able papers in the "Transactions" of the Highland Society, that no one can be at a loss to estimate the expense for himself; besides which, the fluctuations in wages and in the price of iron, and local custom and material, are so constantly modifying what may be laid down as rules, that the matter must be left eventually to the judgment of the planter. Many hints, however, in local methods of fencing may from time to time be picked up and introduced with advantage into districts where the bondage of custom or the abundance of any particular material has firmly established an undesirable kind of fence. An instance may be taken from the method pursued in so many parts of Scotland of fencing plantations with stone walls. As regards the mere question of what pleases the eye, the stone-wall may be condemned at once, for no kind of fence destroys the beauty of a landscape more thoroughly than the grim, uncompromising "stone-dyke." It is moreover in exposure a thoroughly bad fence for young wood. The wood immediately behind it is sheltered till the young shoots reach

the level of the coping, and then the blast shaves along the top with double force. A hedge and ditch, a stake and bound, or even a wire fence is much better for the young wood. No fence, in the writer's opinion, looks better, or is more thoroughly sylvan in character than a railing made of the poles thinned out of adjacent woods; and where wood is plentiful, it is probably as cheap a fence as can be made. Wire fences with iron standards are very good in park scenery, as, with a little exercise of judgment, they can be made almost invisible; but great damage is sometimes done to wire fencing in a gale of wind. One tree falling across a wire fence of course spoils the whole length. The terrific gale of February, 1868, will long be remembered in certain parts of central Scotland for the immense havoc done in a few hours. It was singularly local in its effects, spreading destruction in certain parts of Stirlingshire and Perthshire, while places on each side of its track escaped almost entirely. At one place, not far from Stirling, the trees blown out in those few hours were sold on the ground for £2000. The woods at this place were nearly all enclosed with wire fences, and no one who saw the scene of destruction will ever forget it. Splendid trees, principally Scotch Fir and Larch, lying in ranks of scores and hundreds, and hardly a length of wire fencing but was broken and twisted. Nice judgment is required in tracing the outer boundary of a wood, especially in hilly or undulating ground. Too often the contours of the ground are disregarded, and belts or clumps are laid out in a fashion distinctly opposed to the natural. Figs. 1, 2, and 3 may be taken to illustrate this point. They represent a hill of the most ordinary character, as like an inverted bowl or a molehill as possible, but the natural arrangement of the woods in fig. 1 gives the hill such an imposing character that it is difficult to believe that the contour of the ground is precisely the same as in figs. 2 and 3. Fig. 3 is a sketch from memory of a hill visible from the line of railway between Beattock and Carstairs. Sometimes an attempt is made to avoid formality by an unmeaningly serpentine outline, the effect of which is often as artificial as a rectangular design. On level ground the line of boundary is of less consequence, as less of it is visible at once. Straight lines in such a position are very often as good or better than curved ones, and the labour and expense of fencing is, by their adoption, considerably reduced, especially if wire fences be used. But advantage should be taken of every rocky knoll or clump of Furze at the edge of the wood, behind or through which the fence may be run with good effect. In park scenery no fence should be retained longer than necessary. The pictorial effect of removing fences as the trees within them are large enough not to suffer from cattle is invariably good; at the same time great caution must be observed not to throw a wood open too soon. Most forest trees are ready to stand unfenced when from fifty to eighty years old, but this period varies according to soil and climate. An intermediate stage may be adopted by removing the outer fence and placing a new fence within the four or five outer ranks of trees. It should be remembered, however, that throwing open a wood is a very delicate operation; the writer has known cases where it has been done too soon or too suddenly, which have resulted in the almost total loss of the wood, partly from the sudden chill to the stems caused by simultaneous thinning and removal of the fence, and partly from the disappearance of undergrowth and consequent denudation of the roots. But the results in every case where fences have been successfully removed from woods are so markedly picturesque that one should ever be looking out for a suitable opportunity of removing them.

Best Trees for Sea Exposure.

The British Isles have such an extent of sea-coast that in proceeding to consider the trees which experience has proved to be useful for profit and ornament, it may be well to select those trees which can be thoroughly recommended to resist a direct exposure to the sea-blast. The list is very limited according to present knowledge, but even this fact ought to have its merits, because when the properties of these trees are realised, there will then be no doubt what species to put next the sea. Let it be supposed that a plantation is to be made in an extreme maritime exposure, such as many parts of

the west coast of Scotland. The climate is very moist, the soil varies from almost pure sand to hazel loam, the latter genial but shallow, and the subsoil glacial till. In such a position, of course, the wood is mainly for shelter; it is half-a-mile long, less or more, and from 200 yards to 300 yards deep. The old-fashioned way would be to fence it in probably with a stone-dyke, and plant the whole breadth with mixed trees. The result in course of time would be a certain amount of shelter, such shelter as may be had from a dense scrub, which begins to develop into something like trees at the leeward verge of the enclosure. Far "better a wee bush than nae bield;" but woodcraft can accomplish better things than these.

Fig. 1.

To begin with, the fence facing the sea. Perhaps it has to be planted in shifting sand, and will constantly be drenched by showers of spray. Let it be composed of the Sea Buckthorn (*Hippophaë rhamnoides*), a grey-leaved, deciduous orange-berried shrub, with strong thorns, which can be bought cheaper than Holly; it will very soon, in such a position, make an impenetrable fence, growing eventually from 10 to 15 ft. high, and sending up numerous suckers all round. Of course it will require protection from cattle until well established into a hedge; such protection may be given by a wire fence or wooden paling. The worst fence that could be put in a situa-

Fig. 2.

tion such as this would be a stone-wall or earth-bank. This Buckthorn is not particular about soil. Plant it anywhere near these, and it will soon make itself at home, but it is especially so in drifting sand-hills, whose vagaries it is capable of arresting. Then, behind the Buckthorn, you may proceed to plant the prince of all sea-side evergreens, *Pinus Pinaster*, the Cluster Pine. Having already in Vol. VI. of THE GARDEN (p. 566) described and illustrated the merits of this tree for sea-side planting, it is unnecessary to say more than recommend its use along the windward side of the imaginary wood we are planting. Three or four rows of this Pine will raise sufficient shelter for less maritime species; next to it may with confidence be placed three other Pines and a Cypress, namely,

Pinus austriaca, *P. laricio*, and *P. insignis*, and *Cupressus macrocarpa*. The two latter, though of comparatively recent introduction, have already proved themselves to be of high value in sea exposure. Although we are supposed to be planting for shelter, yet the value of the timber may be taken into account. The timber of the *Pinaster* is of little value, being very light, and serviceable only for packing cases and such purposes. Formerly the Oranges exported from the Azores were packed in cases made of *Pinaster* Deal, but of late years the Japanese Cedar (*Cryptomeria japonica*), a tree of more rapid growth, and even softer and lighter wood, has been planted for that purpose. The timber of the Austrian and Corsican Pines is extremely valuable, being both strong and durable; and the timber of *Pinus insignis* and *Cupressus macrocarpa* is said to be of good quality. If any marshy pieces of ground are included in the proposed wood, they should be planted with *Abies nigra* (the Black Spruce), an excellent sea-side tree, which delights in cold wet soils. Now a beautiful wood may be formed with these materials alone—a truly evergreen wood, for none of these trees change colour, except occasionally the Corsican Pine, even when under the influence of the sea-spray; but suppose a belt of these 100 yards wide has been planted, and it is wished to introduce some other forms of evergreen or deciduous trees, they may be selected from the following list, the names being given according to the degree of hardness in such a situation:—Sycamore, Scotch Elm, Scotch Pine (especially in clay soils), Beech, Birch, Huntingdon Willow

Fig. 3.

(for wetter parts), Silver Fir, Ash. As undergrowth, none is more beautiful or more suited to a sea exposure than Holly, but it is unfortunately the case that it is no use planting either it or Laburnum (another good small sea-coast tree), unless it can be protected from rabbits. Smaller undergrowth may be obtained by the following rabbit-proof plants, which should, however, not be planted till the wood has received its second thinning, unless some open spaces can be found for them along the edges of drives, &c. They are *Daphne laureola* (the Spurge Laurel), *Daphne mezereum*, *Berberis Darwinii* and *dulcis*, *Mahonia*, *Hypericum calycinum*, and others, *Vinca major* and *minor*, *Ruscus aculeatus* (Butcher's Broom), *Fuchsia Biccartoni* (in open places near the sea), *Rhododendron ponticum*, *Euonymus europæus* (Spindle tree), and *E. japonicus*.

Choice Trees and Shrubs.

With the above-named well-proved species and varieties a wood may be formed which will not only thrive under conditions which would cause the failure of indiscriminate planting, but which may be made highly ornamental at the same time. We may now consider some of the principal and most desirable species of Conifers and hard-wood trees which have been introduced of late into the country, and which, as a rule, require more shelter than our hardier native trees. One of the commonest errors which mislead gardeners, foresters, or amateurs, consists in the idea that every novelty is a desirable acquisition. The old-fashioned and, till recently, nearly obsolete system of flower-gardening, which we are now welcoming back among us, was brought

into discredit by this very thing; every attainable species of hardy plant was indiscriminately added to the herbaceous collection, till the collector one day awoke to the fact that, although he might have a very large collection of exotic hardy plants, yet half of them were no better than weeds. Unless a botanical collection is desired, all gardening depends upon judicious selection, and, on a larger scale, so does forestry. Coniferous trees, especially, have of late years been introduced from all parts of the earth in such number and variety, that it is useless, except in the very largest parks, to attempt a collection of all the known hardy sorts. Hence it will be observed that the list which follows is very far indeed from being a comprehensive one; but an attempt has been made in it to name only those species which have been ascertained to be equal or superior in this climate to those that we already have. Where so much material for choice exists, the only safe recommendation of a new tree is an affirmative answer to each of the following questions:—"Is it perfectly hardy in all seasons of our climate? Is it markedly distinct from species already in common cultivation? If so, is it superior in beauty, or productive of better timber, or more quickly remunerative than those we have?" Nothing but the highest and most distinct degree of beauty justifies the substitution of new species for old and tried native and exotic trees, for we already have among our Scotch Pine and Silver Fir, Oak, Beech, and countless others an immense variety of beauty and usefulness.

Abies.

To begin then with a selection of Coniferous trees, the first on the list is *Abies*, or the Spruce family. Although there is no indigenous member of the family in this country, it has long been known as familiarly as most native trees from the extensive use of *A. excelsa* (the Norway Spruce) as a forest tree, and also in a less degree *A. nigra* (the Black American Spruce). The Norway Spruce is very impatient of the direct action of sea-breezes, and should not be planted till a certain amount of shelter can be obtained for it. The Black American, however, is an extremely good sea-coast tree, and prefers a damp cold soil. It is not worth planting in dry, sandy soils, but in a suitable situation; although the growth is somewhat slow, it becomes a very beautiful tree, with bluish-green foliage and purple cones. Those who have only seen it in dry soils have little idea of its beauty; for it is truly, when in health, more worthy of admiration than many novelties which have more attention bestowed on them.

ABIES ALBERTIANA (syn. *Mertensiana*).—This is the most graceful of all the Spruces, and may be described as combining the foliage of the well-known Hemlock Spruce (of which it used to be considered a variety) with the growth and drooping leaders of *Thuja gigantea* or *Cupressus Lawsoniana*. Of perfect hardiness, very rapid growth, and distinct habit, it can be very highly recommended for sheltered situations; but it is unsuited for exposure to constant high winds. A year's growth of a specimen at Culroech, in Stirlingshire, exceeded 7 ft.

ABIES DOUGLASSII.—There is now no doubt that in this tree we have one of the most valuable additions to our forest trees, whether in an ornamental or commercial sense, that has ever been made. It should be extensively planted, but not in extreme exposure, as the annual growth is so rapid that the leading shoot becomes deflected under the influence of long prevailing winds. It is perfectly hardy, and does not seem particular as to soil.

ABIES MENZIESII is a fine forest tree, distinguished from other Spruces by its glaucous foliage. It is very symmetrical, and of rapid growth, but is more likely to be found valuable as a timber-producing tree than on account of any special charm that it can give to the home landscape. It is undoubtedly hardy, and prefers a somewhat damp soil. It is not calculated to thrive in a directly maritime exposure.

ABIES MORINDA (syn. *Smithiana*, *Khutrow*), a beautiful Spruce, which attains to a great size in the Himalayas, where it is found at greater altitudes than the Deodar. It is, unfortunately, not so hardy as the latter tree, and liable to be injured by late frosts; but in temperate districts a sheltered glade may well be devoted to the *Khutrow*, where its rich drooping foliage will be protected from high cold winds.

With these four Spruces, in addition to the Norway and Black Spruces already mentioned, the planter may be satisfied that, according to present experience, he has the pick of the family. The Hemlock Spruce rarely attains greater proportions in this country than those of a large shrub, and *Abies orientalis*, though very neat and hardy, is not distinct enough in character, and is too slow in growth to warrant its substitution for the common Norway Spruce. The remaining species of *Coniferae* will be considered in another paper.

The Japan Pear on Walls.—I was reminded to-day (14th March) of the large tree of the single red *Camellia* in the gardens at Caserta by the size and beauty of the deeply-coloured blossoms of *Pyrus japonica* on the wall of a cottage on a cold English hill-side. The wall was covered from top to bottom, and from one end to the other, with this lovely early tree, every blossom, slightly protected by an eave of 6 in. or so, being bright and perfect. The flowers had not yet opened on the part of the tree trained over the porch, and which had not the benefit of the wall.—W. R.

Lilac Hedges.—Few deciduous shrubs form more charming hedges in early summer than Lilacs. We have a large orchard enclosed by one here, a wire fence being added as a safeguard, and most lovely it is when the Lilacs are in blossom. The only pruning required is thinning out the longest straggling shoots annually, so as to keep the base thickly furnished with young growth. Hedges of this kind should not be clipped, as in that case most of the bloom would be sacrificed, and a stiff formal aspect imparted to them which would rob them of half their beauty.—J. GROOM, *Henham*.

Cupressus Lawsoniana in Flower.—In No. 187, Vol. VII, of THE GARDEN, you gave a coloured plate of this tree. I admired it very much, but at that time I had never seen the tree itself in flower. A specimen here, which was planted about seven years ago, I am told, was not doing well and never flowered. Two years ago I removed it to a black peaty part of the shrubbery, and last year it grew vigorously and made a leading shoot 2 ft. 9 in. long. At the present time it is covered with bright red little flowers from top to bottom, and very beautiful. It is now 14 ft. in height.—JOHN CLARKE, *Cork*.

Tree Planting in Public Parks at Southampton.—Mr. Rogers, the well-known nurseryman of Southampton, and this year sheriff of that town, has just been presented by the Corporation with an illuminated address of thanks for his valuable gift of trees and shrubs to the public parks during the past winter. Southampton is peculiarly well favoured in the matter of public lands, and the fine ranges of parks in the very centre of the town are at once breathing spaces and ornamental gardens that cannot be too highly appreciated. The greater portion of the trees are yet young, but a future generation will have boundless cause to be thankful for the foresight that provided them and their children with such delightful spots wherein to find pleasure and means of recreation.

Fertilisation of the Aucuba.—An interesting instance of the fertilisation of the *Aucuba* has been brought under my notice lately. In the nursery grounds of Mr. Hoade, at Addlestone, are now standing some plants full of berries. He does not possess, and never has possessed, any male specimens; and the nearest one in the neighbourhood, to his certain knowledge, is fully half-a-mile distant. This has now occurred two years in succession; those plants, however, which bore berries last year have none on this, and *vice versa*. This instance is more remarkable than the one already cited in your columns—in which although at some distance the source of fertilisation could be traced—in the case I now mention pollen must naturally have found its way to the plants which have fruited; but in what way—by what agency? It is in my opinion a striking warning to hybridisers, and proves how very carefully the process of isolation should be carried out to warrant any certain conclusions being deduced from experimental cross-breeding.—JOHN CORNHILL, *Byfleet*.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Abies grandis and its Forms.—Mr. Hoopes, of West Chester, a horticulturist of much experience among Conifers, considers that *A. grandis* is a good species, but that *A. Parsoniana*, *A. lasiocarpa*, and *A. Lowiana* are well-marked forms of the same, varying in length and shape of leaf, and size of cone.

Purple-leaved Peach.—This is figured in the "Illustration Horticole," t. 224. The leaves are less purple when the fruit is ripe than in spring and early summer, when the growth is immature; but as represented they are still distinctly coloured a fine bronzy-purple on the under side, and purplish-green above. The fruit is of medium size. We doubt if it will prove of great value as an ornamental shrub.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Late Vineries containing Greenhouse Plants.—Who are amateurs possess only one house, in which both plants and late Grapes are grown, the plants will have to undergo some sacrifice if the Grapes be desired to ripen to perfection, as the Vines, to assist their breaking, will require to be kept closer than will suit the health of the general body of greenhouse plants; and if this be not done, especially in the colder parts of the country, there will not only be the difficulty of obtaining a crop of late Grapes properly matured and of the requisite quality, but also of ensuring the proper ripening of the wood for the coming year, which is quite as essential to the Vines as the well-being of the current crop. From a house of the above description all such plants as Polargoniums, both show and fancy kinds, Cinerarias, Primulas, Epacris, herbaceous Calceolarias, Lilies, and Kalosantes, should be removed, and may now be accommodated in pits and frames; even if there be no means of warming, the plants can be kept secure by covering with mats on frosty nights. Zonal Polargoniums will bear the treatment which the Vines require better than the above-named plants, but it is preferable to have them removed. Autumn-struck bedding plants should also be put elsewhere, or they get drawn up weak, and will be in much worse condition at the time they should be planted out than if kept where they will be cooler. Acacias, Genistas, Fuchsias, Amarylises, Azaleas, Abutilons, pot Roses, Ferns, Cassia corymbosa, Epiphyllans, Habrothamnus, Lantanas, and Vallotas, may remain, as they will bear the more confined damp atmosphere which the Vines need. Some air should be given in the mornings, damping the paths and walls in the middle of the day, closing the lights early in the afternoons, and syringing the Vines overhead; so treated they will soon break, when they can be tied up in their places, previously examining the wires to which they will have to be secured. It is a very common error with those who have not had much experience in Grape culture to have the wires in their vineries too near the roof, thus not allowing sufficient room for the leaves to grow without touching the glass, in which case they cannot escape being injured. Another cause of injury from the wires not being sufficiently far from the glass is that in tying up the young shoots in order to keep them as low as the arrangement of the wires will permit, some are liable to break out. A distance of 15 in. from the roof is near enough for fixing the wires.

Vines, which were started earlier and are progressing in growth, must receive regular attention; as they advance it will be easily seen which shoots show the most promising bunches, removing at once those that are not required. It is a great mistake to allow, as is frequently the case, a quantity of useless superabundant shoots to remain longer than necessary, as such neglect draws a certain amount of support from the Vines to no purpose. Young Vines that have been planted two or three years, and have nearly or quite extended to the length of the rafters, should not have too many spurs left upon them. There is no doubt that the root-formation of Vines is correspondingly assisted by the increased number of fully-developed leaves, consequent upon the reciprocity between leaves and roots in any individual plant of whatever kind; but, with Vines, especially young ones, it is a common occurrence to see almost every eye that the canes have produced allowed to grow, thus crowding them with double the number of shoots for which there is room, the result of which is that the leaves have not more than half the space necessary to permit their getting the requisite amount of light and air essential to their full development. When a spur has been allowed to grow from all, or nearly all, the eyes, a reduction of one-half at least would be an advantage; and, if not done at the time the Vines were pruned, the eyes, as they push, may be rubbed off, and the spurs removed after the shoots to be retained have pushed; or, in the case of Vines that have made some progress, the superfluous spurs may at once be taken off, the beneficial effects resulting from which will be seen in the autumn by the bearing wood having double the strength it would have had if all had been left to grow; in the case of late Vines being so treated, a much better chance of getting the wood well ripened is afforded them. As soon as they begin to bloom, cease syringing, at all events until it is over; the most approved practice with experienced Grape-growers is not to use the syringe after the Vines have bloomed, on account of its diminishing the bloom upon the berries; but with amateurs, especially when they have other plants to grow in the same house, it is safer to advise the syringe being again employed daily after the fruit is set until the time it begins to colour, as an important safeguard against red spider. See that all soft-wooded plants from this time forward receive enough water—as the time is at hand when growth progresses at a rate that necessitates considerably more being given than earlier in the season—otherwise the leaves will suffer. All subjects of the description above men-

tioned that aphides will live upon should be examined thoroughly every ten days, as at this season, more than any other, these insects make their appearance; and if once they get established upon even a few of the plants they quickly spread to others, doing serious harm, and requiring a great deal more labour in their destruction than if got rid of as soon as they appear. When a number of plants are affected with these insects fumigation is, no doubt, the best remedy; but where only a few out of a large quantity are at first attacked, it is not desirable to smoke the whole house or pit; the affected plants may be removed and fumigated by themselves under anything that will confine the smoke; but it frequently happens that plants in small frames, when subjected to a sufficient volume of smoke to kill the insects, have their leaves injured. This arises from the fact that the smoke, escaping so much sooner from a smaller space in the frame than in the larger house, needs to be more dense in the former to destroy the aphides than the plants can bear; for this reason I should recommend amateurs, at this season of the year especially, to keep always by them ready for use a bucket full of Tobacco-water, so that any affected plant can be at once dipped, or held over the vessel until it is thoroughly washed by syringing with the Tobacco-water; if this be effectually carried out, not only will the living insects be destroyed, but the eggs also, which later the smoke will not affect. I have for many years found this not only an effectual way of dealing with these insects, but a great saving in labour. Where Roses, which are more susceptible to aphides than any other plants, are grown in pots, the treatment just named will be a simple and effectual means of dealing with them. For Fuchsias, the leaves of which at this season cannot bear smoking, as also the young fronds of some Ferns, such as Adiantums, dipping and syringing are much to be preferred to fumigation.

Chrysanthemum cuttings that were advised to be put in some time back will now have filled their little pots with roots, and should at once be moved into others 6 in. in diameter, using three parts good loam to one of rotten manure and sand, in proportion to the quantity of sand which the loam contains naturally, as the compost should be open enough to allow a thorough drainage of the copious applications of water which these, more than any other plants grown in pots, require. See that they are free from aphides, and, if necessary, dip them in Tobacco-water whilst they are in the little pots; at the same time in all cases take off the tops to induce them to break several shoots, except where they are required to produce a limited number of the finest flowers. When this is the object, it is usual to let the plants grow on without stopping; and when in bloom in the autumn, in groups of two or three colours together on the floor of the greenhouse, amongst Camellias, &c., they are very effective. When all the powers of the plants are concentrated in the production of a very few blooms, Chrysanthemum flowers individually last much longer than if grown in the ordinary way, a quality not generally noticed. When there is any deficiency of plants struck from cuttings, or where there has been an omission in planting them in time, the old stools that flowered last autumn should be broken up, shaking off the soil and dividing them into small pieces. When this method is followed the pieces used should not be too large; two or three of the young sucker shoots that spring from the crown with some roots attached are of sufficient size, for, if large pieces be used, they require pots of an increased size to support them, otherwise they get bare at the bottom before they flower, a condition that spoils their appearance, however numerous or fine the blooms. These easily grown and most useful of all autumn-flowering plants are much less frequently seen well grown than they should be; if they be properly attended to from this time all through the season, they will furnish a magnificent display during the late autumn and early winter. There is no flower that I should so much recommend to amateurs who are commencing plant-growing as the Chrysanthemum, from its easy growth; nevertheless, to be successful in its cultivation, it must never be neglected. A cold frame, where the plants will get plenty of light, is the best place for them now, giving air as required in the day-time, and covering with a mat when there is an appearance of frost.

Lilies in pots will now demand attention. It is a very common occurrence (even when these are accommodated with a light position in a greenhouse, pit, or similar situation) to let them remain too long, so that the shoots get drawn; where this is permitted to occur, no treatment during the season will remedy the defect, which generally ends in the bottom leaves turning yellow and falling off before the flowers are open, completely spoiling their appearance. To avoid this the plants should be moved to cold frames if possible, as soon as they show above the soil; here they should be kept with their tops close up to the glass; the lights should be drawn completely off during the day—unless there is danger of the soil getting saturated by too great a downpour of rain—putting them on again at night, but leaving them tilted, so as to allow an abundance of air

when there is no likelihood of frost. The frames should be placed where they will get all the sun and light possible. If frames be not available, instead of keeping the plants to get drawn in a house, put them under a south wall with a slight framework over to protect from frost, laying the pots down on their sides when the weather is very wet. Where a good selection of Lilies is made they are essentially amateurs' plants, as they afford a succession of bloom lasting a considerable time, and are easily grown, providing a few essentials are not lost sight of. To the fact of their not dying right out when subjected to unsuitable treatment may be attributed their being frequently seen in very poor condition.

Greenhouse Plants.

Solanums.—Few plants are grown to the extent these now are, and certainly none are more cheerful-looking or useful for winter decorations when laden with their rich glossy red berries, a condition in which they may be easily had by starting early with their propagation either by cuttings or seed sowing. If the former method be resorted to, no time should be lost in getting them in, that they may form strong plants for planting out at the end of April, as the quantity of berries they bear depends very much on the early growth they make. Any seedlings now up should be pricked out thinly in pans or pots containing light rich vegetable mould, and then placed where they can be afforded a gentle moist heat, for the purpose of pushing them on. The standard form is perhaps the most desirable to grow them in, as that is most suitable for table decoration. Solanums being largely used and well adapted for that purpose. To have them with clean straight stems, all side growth should be nipped out of the young plants, so that the strength of the roots may be concentrated in the main stem, and that the desired height may be attained as quickly as possible. As growth proceeds they must be tied to neat sticks to keep them straight and support the head after it is formed. If bush-shaped plants be desired, they should be stopped when 3 in. or 4 in. high for the purpose of developing side-shoots, which should again be stopped after they have attained the same length. All old plants become shabby from the berries shrivelling or leaves falling off, prune back at once and place in gentle heat, so as to get them started again ready to plant out next month. Solanums so treated will form large specimens that are sure to be laden with berries, if kept well supplied with water during the summer.

Primulas.—Seed for early blooming, if not already sown, should at once be got in. Place the pots or pans where the soil can be kept moist till the seeds germinate without resorting to the watering-pot. A hand-light, cloche, or piece of glass laid over the pan and shaded so as to exclude the light, will secure the conditions favourable to a quick germination. Sow in a light rich vegetable soil, such as thoroughly decomposed leaf-soil or fine peat, to which a little loam may be added. Old plants from which seed is desired must be kept on light dry shelves well up to the glass so as to insure the pollen becoming ripe and freely dispersed before the flowers fall off and carry the anthers with them. Double varieties that have ceased blooming should now be divided, and, in doing so, as much of the old root-stem as can be got should be secured to each cutting or division. The number of these need only be limited to the quantity of separate crowns the plants possess, for each of these may be split off. Carefully remove any dark-looking portions of old leaf-stalk that appear likely to rot, and so cause the destruction of the cutting. When this is done and they are properly trimmed they should be inserted singly in small pots filled with a sandy peat or leaf-soil. Make a hole in the centre in which to put the cutting, and fill round with sharp sand; place the pots where they can receive gentle heat and be kept moist without the aid of watering, as this should not be applied till the roots begin to form, if the cutting can be kept fresh till that time. To assist this operation the pots should be plunged in damp Moss or Cocoa fibre to prevent the air acting on them. A light shelf in a close moist house or pit, or a propagating box where they are not kept too confined, will be found the best place for them. Besides the old double white there are now many beautiful coloured sorts that are very desirable for the sake of variety, and as they all last in bloom much longer than the single kinds, they are each deserving of extensive cultivation.

Linum trigynum.—There is generally a great scarcity of yellow flowers, especially among greenhouse plants, and as *L. trigynum* blooms naturally throughout the winter without the aid of artificial heat, it is doubly welcome on that account. When well grown and free from spider—an insect to which it is very subject—it blooms in the most profuse manner possible, every twig, however small, being usually laden with a number of flowers that keep on expanding in regular succession. In clearness of colour, they are quite equal to *Allamandas*, and are quite as indispensable for warm

greenhouse or conservatory decoration during the winter months as *Allamandas* are for the summer. Old plants that have now ceased blooming should at once be placed in moist heat, to realise an early supply of cuttings. See that they are free from red spider before attempting to propagate or starting them to grow for that purpose, as they can be much better cleaned before the young tender leaves appear than afterwards. Keep them well damped overhead to encourage young growth and prevent the spread of insects. Cuttings taken off with a heel strike readily in close moist heat, after which they should be kept growing on in a damp atmosphere, such as *Fuchsias* or plants of that kind delight in. A loose open soil suits them best, and this should consist principally of peat and loam, in the proportion of two-thirds of the former to one-third of the latter. As they require liberal supplies of water while making their growth, the pots should always be well drained. Dryness at the roots is sure to induce red spider, and to prevent any rapid changes taking place with regard to the soil, the pots should be kept plunged in some light loose material.

Hardy and Half-hardy Ferns.

These will now be pushing up their young fronds, and, where well sheltered from spring frosts, should at once have any protection, such as Bracken or any similar covering, removed from their crowns. If their winter covering be allowed to remain on after they once make a start, it is almost impossible to remove it without damaging the young growth, the effects of which will be seen for the rest of the season. In the case of the more tender varieties this may be replaced by a mulching of half-decayed leaves, which will not only afford the necessary protection now, but will be of great benefit during the summer by giving a gentle stimulus to the roots besides keeping them in a uniform state as to moisture. As the fronds protrude through this they should have the additional shelter of a few branches of evergreens stuck round them, so as to ward off cutting winds and late spring frosts, that would otherwise be fatal to the young growth. Even the hardiest are very liable to injury just as they are unfolding their fronds, and, therefore, the site for its out-door Fernery should be as sheltered as possible. Where it is desired to divide and increase any, or to effect a re-arrangement, now is the best time to commence such operations, as at no season do Ferns transplant so readily, and with so little check to their future development, as when they are just beginning to grow. In dividing them, it should be done with a sharp instrument, making a clean cut right through the roots. See that each piece has a separate crown, or that the fleshy roots of such as creep under the surface have the necessary eyes to push into growth. Where peat is not easily accessible in sufficient quantity to mix with the loam for the purpose of planting the more choice kinds, it may be substituted by a good dressing of leaf-soil, which answers almost equally well. If the latter can be obtained in sufficient quantities to top-dress each of the plants they will be materially benefited. Those who contemplate planting out any supposed half-hardy varieties should wait till all danger from spring frosts is over, and meantime the plants should be retarded as much as possible, that they may grow altogether in the positions assigned them, as that would afford them a much better chance of establishing themselves. Several of the best of the greenhouse kinds will stand out in loose well-drained soil, with slight protection during the winter.

Woodwardia radicans.—This is one of the grandest Ferns, and is sure to command admiration if placed in a position where it can show off its magnificent fronds, which are even finer and richer in colour, in favourable situations out-of-doors, than they are under glass. As these grow from 3 ft. to 5 ft. in length, and droop in a gracefully pendulous manner, they should be placed in suitable elevations or on the sides of steep sloping banks where the fronds can assume their natural drooping habit and be seen to the best possible advantage. A noble Fern of this species has stood for years in the Fernery here with only the protection of a few leaves or brakes thrown over the crown; it will be found quite hardy in many localities. *Cyrtomium falcatum*, another fine Fern, also should be in every collection, either indoor or out, as its rich shining deep green fronds render it quite as striking among Ferns as the Holly is among evergreens. It will stand ordinary winters without any protection whatever, while its perfect safety may be insured by scattering and making secure a handful or so of leaves over the crown. *Onychium japonicum* is a very elegant variety, alike valuable in the greenhouse as in the hardy Fernery. The fronds of this, when ripe and mature, are valuable as an accompaniment to flowers, whether for bouquets or for table decoration; and they continue fresh for a long time; they are very light and feathery in appearance on account of the fine divisions of the fronds. This Fern will be found nearly hardy in most situations, and may be kept quite safe by protecting the top of the soil over its roots.

Pteris scaberula.—This beautiful Fern, with the protection of a little leaf-soil scattered over its small very-riking stems, may be safely wintered in the hardy Fernery. Being a surface-rooter, it should be planted in a rough peaty soil. The fronds of this grow about 1 ft. high, and are as elegant as any of the Cheilanthes. No Fernery, however small, should be without it, as it is one of rare beauty, either for baskets or planting out on a rock in the natural style, on which it rambles and grows in perfection.

Pteris cretica albo-lineata.—This is a very distinct variety, having a yellowish-white band down the centre of each pinna, and on that account forms a pleasing contrast with the green-fronded Ferns. It will be found sufficiently hardy for outdoor cultivation with the same kind of protection recommended for the others. The fronds of this show well among flowers, and it is deserving of a place even among the most select kinds in the greenhouse. *Lomaria magellanica* and *chilensis* are both noble-looking Ferns, that should have a place in every collection, and are alike valuable both indoors and out. *L. chilensis* has fronds upwards of 3 ft. in length, rising from fast creeping stems that soon spread in various directions and make large handsome masses, which have a strikingly pretty appearance. *L. magellanica* has fronds of about 18 in. long and from 6 in. to 9 in. wide, spreading and arching in the most graceful manner. *Oncoclea sensibilis* is likewise a grand Fern, having fronds of a most pleasing pale green colour, varying in height from 1 ft. to 2 ft. The creeping stems travel rapidly just beneath the surface of the soil, where the latter is loose and favourable. To have it in perfection it should have a damp situation, as it luxuriates in moisture. It is extremely ornamental, and quite distinct from any other in cultivation.

Struthiopteris germanica is a very stately-habited Fern having fronds upwards of 3 ft. long, arranged much in the same way as the feathers of a shuttlecock. These are of a light greyish-green colour, and contrast well with others having a deeper hue. The fertile fronds of this rise from the centre of the tree-like stem, and give the plant a very ornamental appearance. *S. pennsylvanica* greatly resembles the above, and no hardy Fernery should be without either one or the other. Both are readily increased from their underground stolons, which they send out freely wherever the soil is loose and open and favourable to their spreading. They should have a deep moist soil, or they become shabby rather early in the autumn from the attacks of trips, to which they are always liable if grown in dry places. By the sides of running streams they have a very striking effect. Where sufficient moisture can be obtained *Osmunda regalis* should find a place. This does best where it can have its roots in running water, or where there is plenty of moisture in the soil. Where conditions are favourable the fronds attain a height of 5 ft. or 6 ft.; it is a truly regal Fern, and well deserving the name it bears. There is now a crested variety of this in cultivation that is very ornamental and quite worth adding to any Fernery that has sufficient moisture for its accommodation.

The Wild Garden should, if possible, be linked to the hardy Fernery, as Ferns and wild flowers are fit associates for each other. Hardy Palms, too, and a whole host of ornamental plants may be here introduced that would be quite out of character in any other portion of the ground, and therefore, where there is sufficient space, the hardy Fernery may be rendered if not the most ornamental at least the most interesting appendage to any grounds. Plants never look so beautiful as when they can have perfect freedom and grow unrestrained in their own natural way, without the pruning, training, and restriction necessary when cultivated in dressed portions of the garden. For the guidance of those engaged in the formation and planting of such places, it may be well to enumerate a few of the plants suitable for giving them a wild natural appearance, or such as associate well with the character which such portions of the ground should be made to assume.

Bamboos, in their different varieties, are particularly suitable, especially *B. Metake* and *B. gracilis*, as their gracefully-pendulous habit and light feathery foliage render them eminently adapted for portions of this kind. *B. gracilis* is a plant that can scarcely be misplaced, and should have a position assigned it somewhere or other in every garden. *Polygonum Sieboldi* is a very suitable plant for places of this kind, but, on account of its spreading nature, it requires keeping within due bounds; *Barberia nepalensis*, *Aralia Sieboldi*, and plants of this class are all suitable for associating with the above, and when well placed afford quite a tropical appearance of a permanent character; *Phytolacca decandra* is likewise suitable, but this should have a warm, dry, sunny aspect assigned it, or it does not fruit freely. Merging by degrees to the more wild part, the ornamental Brambles, wild Clematis, climbing Roses, Honeysuckles, and similar plants, may be used with good effect. *Carex pendula* is well adapted for associating with Ferns,

where a wet place can be assigned it. In suitable positions it attains a large size, throwing up its sedge-like leaves and flowers to a great height. A large plant of it here, growing where it can reach the water, has a trunk or tuft 3 ft. in height, and, when in bloom, is an object of great interest and beauty.

In shady positions, common and other Primroses, Cowslips, Bluebells, Snowdrops, wild Anemones, Violets, and other early spring-blooming plants, natural to wild positions, should be planted with an unsparring hand; while, in the more open situations, Foxgloves, Pulmonaria, Solomon's Seal, Squills, Arums, Funkias, Aconites, Aubrietia, Daphne, Lithospermum prostratum, Omphalodes verna, and many others that *Cneorum*, hardy Geraniums, Forget-me-nots, and many others that will suggest themselves to the enthusiastic horticulturalist, should be made use of. *Gunnera scabra*, with its huge leaves and singular-looking crowns, is just the plant for introducing in certain positions in the hardy Fernery. It will grow to perfection in a deep loose soil, and it thrives equally well both in shade and sunshine. Lily of the Valley must not be overlooked; this vegetable soil, and sufficient light and air to develop strong crowns.—J. SHEPPARD, *Woolverstone Park*.

Digging Herbaceous Borders.

My advice is not to dig—in the usual acceptance of the term. The only implement that should be recognised in a herbaceous border is a four-tined steel fork, and if one be obtainable that has seen some service all the better, as it will be in every way more suited for the work than a new one. I, of course, presume that during the frosty weather, as I before recommended, a dressing of well-decayed and tolerably concentrated manure had been applied. All, therefore, that is necessary in the way of digging will be to turn in the manure to a depth of 3 in., or just sufficient to get it covered with soil; by following out this suggestion, the fact will be practically endorsed that, as a rule, herbaceous plants enjoy a firm and undisturbed freedom in which to grow, and you will avoid the risk of the destruction that always follows the use of the spade. Now, just as the crowns are beginning to show signs of life, and bulbous plants are well out of the ground, is the time for this operation.—J. C. N.

Indoor Fruit Department.

Peaches.—Trees in houses started early will have completed their stoning process, and, where a heavy crop was left until this took place, thin out at once to the number required, leaving the finest fruit in the best positions evenly distributed over the tree. Do not lay the young wood too thickly, but in such a manner as to admit all the light possible. Advance the night temperature to 60°, with a corresponding rise by day. Admit air on all favourable occasions, and retain a little during night; use the syringe night and morning, applying it forcibly upon the trees, so as to prevent red spider from lurking in out-of-the-way places. Pay attention to the borders as regards water, and, if the drainage be efficient, well supply them. If the trees be old and the borders long in use, assist them by a copious supply of manure-water. Trees in succession houses in flower should be assisted to set by the use of a camel's hair brush; go over the trees twice a week, choosing fine days about noon for the operation. Attend strictly, as previously recommended, to disbudding, pinching, and tying. Maintain a night temperature of 55° and a day temperature in proportion to the state of the weather. Start late houses, so as to have the fruit in before that on outside walls; water the border well, and syringe the trees and all available surfaces, which will be of more benefit to the trees than steam from the hot pipes.

Figs.—Those that were started early will now be approaching maturity, and where such is the case allow a somewhat freer and drier circulation of air. Water sparingly, but at the same time give sufficient to keep the trees in health; discontinue manure-water when the fruit approaches maturity, and give up the free use of the syringe. In many cases the second crop is better than the first, especially that from early trees, much depending upon the light to which they are subjected; good crops cannot be expected from shaded situations. In succession houses, where the fruit is swelling, let the night temperature remain at 60° with air, allowing the house to run up early in the morning. Assist the sun-heat, during cloudy weather, with fire-heat; give a little air when the thermometer reaches 65°, but avoid having on front and top air together at this early season; pinch or prune at the fourth leaf, and prevent the foliage from becoming crowded by disbudding in time; allowing a heavy growth and extra cutting out are injurious, causing as it does a loss of fruit, and destroying the vitality of the tree. Well mulch the soil, and prevent it from becoming soddened; never allow the borders to become dry, otherwise when abundantly watered the fruit will split.—J. HUNTER.

Out-of-Door Roses.

Those who did not prune their Roses in the autumn did well; but, if still unpruned, no time should now be lost in performing that operation and in manuring the beds. The mode of pruning will depend on what the plants are required for, inasmuch as every Rose-grower has a speciality of his own, *i.e.*, pruning for show blooms—for ornamental and uniform appearance—and for cutting purposes. Where Roses are grown for purposes of exhibition, the shape of the trees need not be studied, as in that case the best flowers and strongest buds might be sacrificed, but such plants require close pruning, and the shoots should be well thinned-out. When they break leave only the strongest and healthiest buds, and as soon as the bloom-buds show themselves they must all be thinned to a single bud to each shoot, which should be carefully staked and the plants watched every day in order to destroy any pests that may attack them. If, on the other hand, Roses be grown for ornament, the strong-growing kinds should be carefully selected from among the weaker sorts, and planted accordingly. If a row of standards be required for recesses or sides of a walk, it is advisable to plant Hybrid Perpetuals, and to get them all as near as possible of an even habit of growth, which will require about the same amount of pruning and training; strong-growing Noisette and Hybrid Bourbon varieties would always require heading back, and by so doing the display of flowers would be diminished. In beds the most vigorous kinds should be planted in the centre, and the delicate varieties round the outside, and they should be pruned so as to secure a good full bed. If for display, as well as for furnishing cut blooms, plant varieties that are useful for that purpose, such as Maréchal Niel, Gloire de Dijon, Victor Verdier, Jules Margottin, and others that are good in the bud state; never select any loose, thin-petaled Rose for such purposes. The strong varieties should be planted in places where they can have room to ramble, and they should never be pruned too closely, but tied down or trained to a wall. If standards, prune those of very strong growth back to four or five buds, leaving plenty of wood; if weakly-growing kinds, prune back close to the most prominent buds. Tea varieties should be thinned out and pruned out to the first wood-buds, cutting away all old flower-shoots. Noisettes do not require to be pruned back closely, but leave the shoots long, and tie with string or matting, so as not to allow them to get spoiled during strong winds. As soon as pruning is done, the beds that have not been manured should be dressed with some well-decayed manure, to which has been added fresh loam and a little crushed bones, carefully forking over the dressing some fresh soil, but taking care not to disturb the roots.—H. G.

Hardy Fruits.

Most people will be prepared to admit that the past winter and the spring (thus far) must be classed amongst the most inclement on record; but still the excessive moisture, in the form of snow and rain, does not appear to have had any prejudicial effect on fruit trees generally, at least not from present appearances. On the 20th and 21st ult. we registered here 8° and 10° of frost respectively, and Apricots being in flower, where not well protected, I fear will be destroyed—ours are all safe under a covering of the thickest make of scrim canvas. In late districts, where the blossoms have not unfolded, the buds will be safe, but protection should at once be applied; as also to Peaches and Nectarines and early blossoming Pears, which are quite as susceptible of injury from frost as the former. Now that all planting, pruning, and nailing are finished, and before disbudbing, &c., is commenced, let all trees requiring it be well mulched or top-dressed with fresh soil or manure, whichever may be considered most beneficial for a particular tree. We have come to the conclusion that surface-mulching in fruit culture is quite indispensable, and I would recommend others to adopt the system in preference to constant digging immediately over the roots, which operation destroys any surface-feeders there may be, and drives the bulk of the roots deeply into the ground out of the reach of spade or fork, which would not be of much consequence if the mischief ended here, but being too deep in the soil neither sun nor air can act on them, both of which are essential to the welfare of the trees. Raspberries are especially benefited by a thick coating of semi-decayed manure as a surface-covering, and which should be put on now that the rains may wash the manurial properties to the roots, whilst the litter remains to ward off drought, of which they are most impatient. If Gooseberries and Currants were served in a similar manner the extra and finer produce would more than compensate for the labour involved. The weather has not as yet been suitable for grafting, but it may be presumed that such will now be favourable for the operation, which should therefore be completed with dispatch, the earliest grafting being, as a rule, the most successful. Just now birds—bullfinches and chaffinches particularly—are busy amongst the buds, Pears and

Plums being their favourites; steps, therefore, should be taken to preserve them from their depredations, or the prospects of a good crop may be ruined. A moderate use of the gun is the best deterrent we have yet found.—W. WILDSMITH, *Heckfield*.

HOW TO MISMANAGE A PUBLIC GARDEN.

THE Gardens of the Royal Botanic Society in Regent's Park are so dear to Londoners from their beauty of disposition, and the many attractive exhibitions that have been—and, we trust, will be—held there, that anything which threatens to injure their condition as gardens deserves the attention of the horticultural public. Public gardens governed by a society are, from the nature of societies, not under the best possible direction. The very able and pleasant gentlemen who compose committees of botanical societies ought not, in justice to themselves, to be expected to be thoroughly acquainted with the details of garden management. Nor is the secretary of a society usually supposed to be properly fitted to manage the horticultural details of a public garden. Elsewhere public gardens are in the hands of curators, men skilled in garden management, who are responsible for the state of the gardens. Here the "superintendent" becomes a mere creature of the secretary, is located in a lodge at one of the back gates, and is treated in such a way as to preclude the possibility of any man of knowledge and self-respect retaining the situation for a season. It will hardly be thought credible that the late superintendent had not power to control his own foremen, but such is the fact; countenanced by the secretary, they have been of late accustomed not merely to disobey him, but to laugh at his pretensions to meddle with them. To deprive the captain of a ship (accustomed necessarily to almost absolute control) of all power to get orders executed by his subordinates would not be likely to secure the good management of a ship for many hours in the pleasantest of seas. The course pursued in the Royal Botanic Gardens, Regent's Park, is an equally harmful one. Let there should be any doubt as to the facts, we publish the following extract from the set of rules for the guidance of the new superintendent, directing attention to the passages in italics:

To have, *subject to the general orders of the secretary*, the management of the floral and fruit department of the society's exhibitions, and such correspondence with the judges and exhibitors as may be necessary.

To have the control of all gardeners and workmen in the gardens, and the hiring and dismissal of gardeners and workmen (*except those on the staff*), and the payment of wages in conformity with the regulations of the garden committee.

To keep stock books of all plants, and an account of all plants, &c., received or given in exchange or otherwise. *No plants to be removed from any department or any exchange made without previous notice of the same being communicated to the secretary.*

To attend at the secretary's office every morning to report and receive instructions, and at the same time to hand to the secretary written requisitions (duly signed) for money, goods, and materials, or for extra labour; and daily to hand to the secretary lists and descriptions, with the bills of parcels (if any) of all goods, &c., received and orders executed.

Generally, the garden superintendent is to consider himself under the orders of the secretary, through whom all communications to the council are to be made.

In the second paragraph above given, the words "except those on the staff" mean that the person who ought to be the curator has no power over any but the casual labourers in the gardens. And what is the use of giving him power over these, if the foremen in the various departments may snap their fingers at him? Need it be wondered that with such a system as this the gardens, except for their original grade of design, long ago given them by Mr. Marnock, are perhaps the least noteworthy in the metropolis; that the handsome and roomy conservatory, so well suited for growing the finest specimens that could be desired, rarely contains a noticeable plant; or that the glass-houses are filled with the very poorest specimens of cultivation? It is most unfortunate that gardens so favourably situated and so well designed should be under influences calculated to paralyse the labours of the best of curators, if, under the above arrangement, such an one could be found to undertake the duties. The Council surely cannot have

fully considered the meaning and effect of these directions, or they would not have sanctioned such a system; in any case, they may rest assured that the gardens will never be in a really creditable condition until they place them in the hands of an able curator directly responsible to the council for their condition.

THE LIBRARY.

A FEW SUGGESTIONS ON TREE PLANTING.*

THIS is a pamphlet mainly of interest to planters in New England and written for their benefit, but which is also a valuable contribution to forest literature. It gives many striking instances of the evils occurring from the destruction of forests, and in the latter part embodies a good deal of original and valuable information as to the kinds of trees—European and American—which thrive best on the stony hillsides and waste lands of New England. The following paragraphs illustrate how the author treats this part of his subject:—

The White Cedar.—The White Cedar (*Cupressus thyoides*), although we are here on its northern limit, where it only attains a moderate size, should be planted on account of the value of its wood for fencing and other rural purposes, boat-building, shingle-making, &c., but more especially on account of its natural place of growth, which is always in deep, cold swamps, often near the sea, and overflowed by high tides, a situation in which no other tree of an equal commercial value could possibly thrive.

The White Ash.—In consideration of its market value at all ages, the rapidity of its growth, and the length of time it continues to throw up suckers, the White Ash (*Fraxinus americana*) is the most valuable of all our native trees for planting in this State. Already there is a rapidly increasing export trade of Ash lumber to Europe, Australia, and the Pacific coast, from Boston and New York, and the possibilities of this business can only be limited by the supply. The American is generally acknowledged to be superior to the European Ash in the qualities for which it is especially valued—toughness and elasticity—and in which no other wood can equal it. Australia possesses no other tree which is at all its equal for carriage-building, while west of the Rocky Mountains there is but a single one which can supply its place—an Ash (*Fraxinus oregana*, Nutt.) which, developing into a large and valuable timber tree in Oregon, is less frequent and less valuable south of the California line. Of the economic value of several *Ashea* which grow on the Eastern Asiatic sea-board, nothing is as yet known. It seems, then, that the New England States could command the markets of the world for one of the most useful and valuable of all woods, had they but a sufficient supply to offer. According to Mr. Thomas Laslett, timber inspector to the British Admiralty, the specific gravity of American Ash is 480, while that of the European is 736. The former is, therefore, on account of its greater lightness, far more valuable for the handles of shovels, spades, hoes, rakes, and other hand implements. According to the United States census of 1870, the number of spades, shovels, rakes, hoes, and hay-forks made in that year was 8,347,478, and as our exportation of such implements is rapidly increasing, although still in its infancy, it is evident that the value of Ash will be greatly enhanced at no distant day. It is also used in making ships' blocks, in turnery, and for making the oars of boats. In speaking of the White Ash, Laslett says: "It stands well after seasoning, and hence we get from this tree the best material for

oars for boats that can be produced. They are much and eagerly sought after by foreign governments as well as our own, and also by the great private steamship companies and the mercantile marine of this country; consequently there is often a very keen competition for the possession of them." The manufacture of oars (such a sea-board industry), in pursuit of material, moved from Massachusetts first to Maine, and then to Ohio and other Western States. Ash is coming into extensive use for expensive furniture and for the interior finish of houses, while an immense number of the young saplings are annually consumed in the coopers' trade. Its value for firewood, according to Bull, is 77, the standard (Hickory) being 100, while only four other American woods are its superior in heat-giving qualities. In view of its many uses for purposes for which no other wood can supply its place, it is not astonishing that the value of Ash lumber has largely increased of late years. The present price in the Boston market of the best New England Ash is 85 dollars per 1000 feet, or about 15 dollars higher than that grown in the West. To develop its best qualities, the White Ash should be planted in a cool, deep, moist, but well-drained soil, where it will make a rapid growth. That the plantation may be profitable as early as possible, the young trees should be inserted in rows 3 ft. apart, the plants being 2 ft. apart in the rows. This would give 7250 plants to the acre, which should be gradually thinned until 108 trees are left standing, 20 ft. apart each way. The first thinning, which might be made at the end of ten years, would give 4000 hoop-poles, which at present price would be worth 400 dollars. The remaining thinnings, made at different periods up to twenty-five or thirty years, would produce some 3000 trees more, worth at least three times as much as the first thinnings. Such cuttings would pay all expenses of planting, the care of the plantation, the interest on the capital invested, and would leave the land covered with trees capable of being turned into money at a moment's notice, or whose value would increase for 100 years—making no mean inheritance for the descendants of a Massachusetts farmer. The planting of the White Ash as a shade and roadside tree is especially recommended, and for that purpose it ranks, among our native trees, next to the Sugar Maple.

The late M. Charles Barillet.

Change.—Weigelas, Deutzias, Forsythias, Philadelphus, and Viburnums—we need not particularise further—are as common in gardens as Violets in the woods and Corn Flowers in the fields. They are all fine—many of them faultless it may be. But for the same reason that we do not make beds of the Corn Flower in our gardens ought we to avoid in future these shrubs which, greeting us from every garden, have in a measure lost their charms. There is no more reason why our gardens should be furnished alike, than that our houses should be built and painted alike, furnished alike—or that people should dress alike. Indeed, as gardens are mainly objects of beauty, while houses, furniture and dress are mainly matters of necessity—there is stronger reason why gardens should not be copies of each other. We ("Moore's Rural") should like our readers to "shop" a little for shrubs, and give a moiety of that consideration to variety in their gardens that they bestow upon dress.

THE LATE M. BARILLET.

THE most active and popular person in charge of the public gardens of Paris previous to the great war was Barillet. He projected the majority of the most beautiful and extensive gardens in that city. Recently numerous French horticulturists subscribed and erected a memorial tomb and bust in Père la Chaise to his memory, and few men better deserved such honours. He had rare taste and very extensive experience in gardening, and was for a long time superintendent of the then great nursery of the City of Paris as well as of most of its gardens. We reproduce an excellent likeness of him from the "Revue Horticole." An obituary notice of M. Barillet appeared in our columns a short time ago.

* "A Few Suggestions on Tree Planting." By C. S. Sargent, Director of the Botanic Garden and Arboretum at Harvard University. Boston: Wright & Potter.

SOCIETIES AND EXHIBITIONS.

ROYAL BOTANIC SOCIETY, REGENT'S PARK,
MARCH 29TH.

THIS, the first show of the season, was, on the whole, a very interesting one, Hyacinths and Cyclamens more especially being well represented, and a very good strain of *Cinerarias* came from Mr. James. Messrs. Veitch & Sons and Mr. B. S. Williams showed good collections of new and rare stove and greenhouse plants in the miscellaneous classes. Mr. Ward furnished an effective group of stove and greenhouse plants, to which the first prize was awarded in the amateurs' class. Among these we remarked a splendid variety of the scarlet-spathed *Anthurium*, named *Wardii*, *Odontoglossum Pescatorei*, bearing three very fine-branched spikes, a well-flowered example of *Lycaste Skinneri*, *Dendrobium nobile*, *Acacia longifolia*, *Eriostemon intermedius*, and *Cytisus racemosus elegans*. Mr. Ward also staged a well-grown group of *Azaleas*, the principal attraction being a well-flowered example of *A. Borsig*, a fine double-white variety. Mr. J. Douglas had six large and well-flowered specimens of *Deutzia gracilis*, nearly a yard high, perfect masses of bloom. These were old plants, trained closely in and forced every season for decorative purposes. The best examples of *Lily of the Valley* came from Messrs. J. Carter & Co., of High Holborn.

Botanical Certificates were awarded to the following new or rare plants:—

***Adiantum digitatum* (Veitch).**—A distinct and handsome stove Fern, having large bright green tripartite fronds, each when fully developed nearly a yard in length, the pinnae being semi-circular, and irregularly slit or lobed. The whole aspect of the plant is very graceful, the pinnae being borne on a slender wire-like rachis.

***A. luddemannianum* (Veitch).**—This is simply a curiously-crested form of our British Maiden-hair Fern (*A. Capillus Venerei*), from which, however, it differs considerably, the pinnae being clustered to wards the end of the erect fronds, so as to present a crested appearance.

***Abutilon Darwinii tessellatum* (Veitch).**—An erect-growing very ornamental plant, especially in a young state; it has cordate leaves boldly trilobed at their apices of a soft green colour, blotched conspicuously with golden yellow. The flowers, which are borne in axillary fascicles, are bell-shaped, the colour being a bright red, inclining to vermilion.

***Brahea filamentosa* (Veitch).**—One of the most distinct of all stove Palms; it has large fan-shaped foliage of a soft glaucous colour, the marginal divisions of the fan-like leafy portion being furnished with long whitish filaments; it is a kind which well deserves attention.

***Grevillea Priesii* (Veitch).**—A shrubby plant of dwarf habit, its frizzly-out foliage closely resembling some of the grey Lichens, or the divided glaucous leaves of the common Southernwood. Little plants of it, a foot in height, are very pretty, the extremity of each branch being terminated by a dense cluster of bright rose flowers, something like those of *G. rosmarinifolia*. It is an Australian shrub, and well deserves a place among greenhouse plants.

***Odontoglossum Chestertonii* (Veitch).**—This is one of the most distinct of the *O. Alexandræ* group; it has creamy-yellow flowers conspicuously blotched with purplish brown, the lip being suffused with golden yellow. Being a very distinct and ornate plant, it well deserves culture wherever variety is desired.

***Rhododendron Princess of Wales* (Veitch).**—This is a hybrid between *R. Princess Royal* and *R. Lobbi*, and bears beautiful trusses of vivid rose flowers, the tube shading into white. It is one of the best of a very attractive group.

Floral Certificates were given to the following:—

***Hyacinth Princess Louise* (Cutbush).**—This is a double-flowered variety, the colour of which is a rich salmon, the bells being of good substance, and arranged densely on the spike. It is very distinct in colour, and as such deserves culture.

***Tea Rose Madame Francois Janin* (Bennett).**—This is a distinct variety of slender habit, the foliage well formed, and of wax-like consistence. In the bud state it is very beautiful, the colour being a bright orange, shaded with salmon. It seems well adapted for bouquets and other decorative purposes.

***H. P. Rose Comtesse de Serouyi* (Bennett).**—This is a fine flower of good shape. It has flushed satin-like revolute petals, suffused with rose-lilac in the centre. In colour it somewhat resembles Captain Christy, but appears distinct, and, considering the season, was staged in admirable condition.

***H. P. Rose Duchesse de Vallambrosa* (G. Paul & Son).**—A robust variety, somewhat similar in colour to the last-mentioned, but otherwise distinct; it has stout revolute petals, delicately shaded with rose lilac. It was shown in a pot, and had, of course, been forced, but is evidently has much to recommend itself, especially for exhibition purposes.

Hyacinths and Tulips.—Hyacinths were staged, on the whole, in excellent condition, Messrs. Barr & Sugden and Messrs. Cutbush & Sons being the principal exhibitors of them in the Nurserymen's Class; and Mr. J. Douglas, Mr. Weir, and Mr. Moorman represented the Amateur

growers. Some of the spikes were very fine, and among the best of them were the following:—*Mont Blanc*, a fine single white; *De Candolle*, single lilac; *Blondin*, single blue; *La Grandesse*, single white; *Garibaldi*, single crimson; *Charles Dickens*, single blue; *Ida*, single yellow; *Koh-i-noor*, bright rose; *Howard*, Lord Macaulay, and *Ristori*, rosy varieties. *Csar Peter* is one of the best of the large-flowered light blue, and *Mario* is a good purple; *King of the Blues* is an excellent dark variety, as also is *Havelock*; *Blondin* and *Lord Derby* were also staged in good condition; *Mimosa* is a dense purplish blue, and *Cosmos* a tall and lively pink variety of good form; *Ida* is certainly the best yellow, a kind which enriched the appearance of several groups, being very lovely and delicate, when contrasted with the vivid purple, blue, and rosy varieties. Tulips were staged in excellent condition, especially by Mr. J. Douglas, who had a well-grown group, in which white *Potzebakker*, *Vermilion Brilliant*, *Keizer Kroon*, and the deep rose *Proserpine* shine conspicuously; *Pabiola* is a distinct white variety, flaked with carmine; and *Van der Neer* is a good purple.

Miscellaneous Plants.—A small but very effective group of Orchids, Ferns, and other decorative plants came from Messrs. Veitch & Sons, of Chelsea, and among these we noted the new golden-foliated form of *Abutilon Darwinii*, several *Amaryllids*, *Rhododendron Princess of Wales*, a hybrid between *R. Princess Royal* and *R. Lobbi*, a very distinct kind, and one which bears its flowers in large trusses, the limb being of a vivid rose colour, and the tube white. *R. Excelisior* is another distinct variety of a vivid rose colour, and the tube white. *R. Excelsior* is another distinct rosy-flowered hybrid between *R. Princess Helena* and *R. Lobbi*. The new *Odontoglossum Chestertonii* was shown in this group, and the new *Adiantum digitatum*, which has long, flexuous, tripartite fronds, the pinnae being of a bright green colour, nearly semi-circular, and irregularly-lobed. This promises to be one of the most distinct and beautiful of all new Maiden-hair Ferns. A new fan-leaved Palm, *Brahea filamentosa*, also shown in this group, is a very distinct kind, the margin of the bright green fan-like lobes being filamentous, like the leaves of *Yucca filamentosa*. Mr. B. S. Williams, of Holloway, sent a miscellaneous group of Orchids, Palms, Ferns, and other decorative plants, and also a very attractive group of new seedling *Amaryllids*, the plants being in many cases very good and distinct. Among the best of the latter we noticed *A. virginialis*, a white-petalled form with a delicate green centre; the *Csar*, velvety-crimson with dark veins; *Oriflame*, vivid scarlet; and *Princess of Wales*, vermilion. Several new seedling *Gloxinias* were shown by Mr. B. S. Williams, one named *Adalina Patti*, being white with a crimson tube; and another, *Empress of India*, white with a purple tube, both being distinct. A good group of *Orchids* in flower was shown by Mr. F. A. Philbrick, of St. John's Wood; among these we observed the new *Platanopogon Mammii*, a kind with a very distinct and rich brown, and also the new *P. Casta*, recently imported by Mr. Low. This is supposed to be intermediate between *P. Schilleriana* and *P. amabilis*, and closely resembles the first-named kind in having marbled foliage and rosy flowers; *P. grandiflora* was also represented by well-bloomed plants, and several *Odontoglossum*, *Lycastes*, and *Dendrobies*, completed the group. A very attractive collection of cut *Camellia* blooms came from Messrs. W. Paul & Son, of Waltham Cross; among these we noted fine blooms of *C. imbricata*, one of the best red varieties; *Chandleri*, very vivid scarlet; the old *Double White*; *Ambrata*, fringed white; *Vallambrosa*, rose; *Lavinia Maggi*, striped; and many others. Messrs. Cutbush also sent a well-arranged stand of *Camellia* blooms; and some fine flowers were likewise furnished by Mr. C. Attrill, gardener to C. J. Freke, Esq., Bank Grove, Kingston. Messrs. W. Paul & Son contributed an extensive collection of gold and silver, tricolor and bronze *Zonal Pelargoniums*, among which we noted Mrs. Turner, a dwarf and effective golden tricolor of good habit; likewise *Midas*, one of the best of the bronze *Zonal* section and *Lady Dorothy Neville*, a very bright silver-edged tricolor, the rosy zone being very vivid. Messrs. George Paul & Son, of Cheshunt, showed a well-grown group of seventeen pot *Roses*, among which the following varieties struck us as being worthy of notice, viz.—*H. P. Duchesse de Vallambrosa*, a fine satiny-petalled blush, something in the way of *Captain Christy*, but quite distinct, and likely to be a good addition to exhibition *Roses*; *Cheshunt Hybrid* (Tea), with ten or twelve lovely rich magenta-tinted flowers; *Shirley Hibberd*, a neat and effective salmon Tea-scented variety; *Marie Van Houtte*, a lemon-tinted Tea, of good form, with fine bronze-like foliage, as also *Duchesse de Serouyi*, a very distinct Tea-scented variety, the creamy flowers of which are suffused with a stand with salmon-rose. Mr. H. Bennett, of Stapleford, sent a large stand entirely filled with lovely little buds of *Madame Francois Janin*, one of the neatest and most distinct of all the Tea-scented *Roses*; it has waxy foliage and golden buds, tinged with salmon, and is one of the most distinct of all *Tea Roses* for button-holes or bouquets. The same exhibitor also furnished a new rosy-lilac *H. P. Rose*, named *Comtesse de Serouyi*, with reflexed satiny petals, and one which appears to be of robust habit, the foliage being very fine and of good substance. Messrs. G. Paul & Son showed four stands of cut *Roses* in excellent condition. Among the different varieties we remarked *Marchal Niel*, *Celine Forester*; *Clothilde*, a rosy Tea kind, with delicate shell-like petals; *alba rosea*, paper white; *Dr. Andry*, crimson; *La France*, satiny Rose; *Perle de Lyon*, yellow, with salmon centre; *Madame Victor Verdier*, and others equally good. Messrs. Carter had a fine bank of *Hyacinths*, Tulips, and other forced spring flowers, including six fine specimens of the rosy Chinese *Dielytra*, in admirable condition. Mr. James, of Isleworth, sent a fine collection of dwarf *Cinerarias*, among which were some of the finest varieties, and a deep carmine kind of good form, named *Acme*, was certificated, as was also a fine blue form named *Dr. Masters*, and one or two others.

"This it an art

Which does mend nature : change it rather : but
The Art itself is Nature."—Shakespeare.

TRANSPLANTING DECIDUOUS TREES IN FULL LEAF.

By JAMES McNAB, Royal Botanic Garden, Edinburgh.

FINDING that my name has been occasionally brought forward in connection with a subject which has been somewhat erroneously called "Transplanting Deciduous Trees in Summer," I purpose giving a few notes of my experience in removing certain deciduous trees at seasons not generally considered orthodox, although not exactly during the summer months. About the year 1840 I had occasion to clear a piece of ground for the erection of a span-roofed greenhouse. The proposed site was covered with evergreen shrubs and a few deciduous trees, the largest being a Sorbus or Service tree, about 25 ft. in height, with a stem 2 ft. 3 in. in circumference. In order to clothe as speedily as possible a piece of unoccupied ground lying to the east side of the proposed house, I resolved to remove the best of the evergreen shrubs and the Service tree. These operations were done during the month of July, at a time when the leaves were all thoroughly matured. I had no hesitation about the evergreen shrubs, none of them being of large size; but I was somewhat doubtful about the Service tree, knowing it to be one of those kinds considered difficult to remove with safety, even at any season, particularly when large. The weather at the time was dry, and the distance to be taken was only 30 ft. About the end of June I had a narrow trench made, about 2 ft. from the stem, and 1 ft. deep, all round; a thorough soaking of water was then given two or three times during as many days. After standing for a week the opening up was commenced, adopting the same plan as is always practised here, and which was described in THE GARDEN for August 1873, viz., the forming of an elongated circular ball, about 9 ft. in circumference and 3 ft. in depth, cutting off any strong roots which protruded beyond the surface of the ball. The mass was then covered with canvas, and afterwards surrounded with thin barrel staves, the whole being thoroughly secured or racked round with a stout rope. The undermining was then commenced, and strong lifting ropes and bottom boards put below. By means of two strong high wooden tressels and iron rollers, worked in movable cradles placed at each end of the tressels, the lifting ropes were brought up over the rollers, and worked by means of handspokes. When raised above the level of the hole (two strong planks, 3 in. wide and 10 in. broad, being placed across it), a low-wheeled machine, 6 in. in height, was run on them, on which the tree was lowered, and after being thoroughly fixed to the machine with the lifting ropes, the tree was drawn on planks to its new situation immediately over the new hole. The planks tressels, and rollers were again adjusted, the plant again suspended, the machine and planks withdrawn, and the tree was lowered into the pit prepared for it. After the removal of all the trappings, some good soil was put round the ball, and the roots spread out, and, after being finally filled up, it was thoroughly watered, the stem, for 8 ft. in height, being covered with Sphagnum Moss, and the surface of the ground mulched with short-cut grass. The top and stem were frequently syringed during the evenings, particularly when dry weather prevailed. During the whole operation not a leaf was observed to droop. About the middle of August a yellow tinge began to show itself over the foliage, which gradually increased till the second week of September, when the leaves began to fall off, thus showing a healthy sign; by the end of the month nearly every leaf was down. During the following spring new leaves were developed as if nothing had happened. No flowers or fruit, however, were produced, but afterwards this tree continued to flower and fruit for many years, when it

had to be cut down to make way for an additional house. During the year 1852 a new class-room was about to be erected, and as the building had to be commenced during the month of August, the ground had to be cleared of trees, and the foundation removed before that time. The only tree on the ground that I was anxious to save was a fine flat-headed specimen of the dotted thorned Fruit (Crataegus punctata), with a stem 2 ft. 6 in. in circumference. This tree was prepared, lifted, and removed, with its large ball of adherent earth, in the month of July, in the same manner as just described for the Sorbus, and is now a fine thriving tree. A large specimen of the Honey Locust tree (Gleditsia triacanthos), which stood in the way of a walk alteration, was prepared and removed during the month of August, 1862, while in full leaf, and is now a fine healthy specimen. Oaks, particularly the variety known as Quercus pannonica, or conferta as it is now called, has been frequently lifted during the months of July and August, and generally done with the ordinary two-wheeled McNab Transplanting Machine, as described and figured in this journal for August, 1873. In all cases their removal has been attended with perfect success, water in every instance being copiously supplied both before and after the operation. I need scarcely say that many Coniferous trees, such as specimens of the genus Pinus, Picea, Abies, Taxus, Cedrus, and others, as well as many large ordinary shrubs, can often be removed with greater chances of success, if done during the month of May when the young growths have fairly started, than if planted when the shoots are entirely dormant. In all such cases, however, it is absolutely necessary that a large, adherent ball of earth be removed with them, and water afterwards freely given. It is by no means usual to remove large evergreen shrubs during the month of May, still, if wanted for any emergency, it can be done, if proper appliances be used during the operation, and subsequent care be given. The first large evergreen shrub I attempted to remove at an unusual season was a Portugal Laurel, 8 ft. in height and 1 1/2 ft. in circumference of branches; the young growths had fairly started all over it, each being fully 2 in. in length. The ball lifted was 3 ft. in diameter. It was removed May, 1848, to hide a particular object. After its removal was effected, surface mulching and frequent syringing were resorted to till the young growths were matured. Syringing was also carried on at intervals during the time the lifting and removal were in progress. By this precaution the young growths had never time to droop, and they kept expanding their leaves as if nothing had happened. This shrub is now a fine, healthy, hemispherical specimen. Many large evergreen shrubs, moved with the greatest care during winter and the early spring months, often remain for a season in a somewhat dormant condition. The check sustained by the operation of lifting often prevents them putting forth young growths the following summer. During the spring, twelve months after being removed, they will push out healthy young shoots. This seeming suspension of vitality frequently occurs with deciduous, ornamental, and forest trees when lifted without balls of earth, as they, too, often remain for a season leafless, particularly if dry weather happen to prevail, but push freely into leaf during the following spring. If, however, they experience a moist autumn, many will be found to push partially into leaf late in the year. This is particularly noticeable with medium-sized Laburnum trees planted during winter and spring, no leaves being produced during the following summer; towards autumn, however, they frequently put forth a quantity of flowers, all the spikes being of small size; the following spring leaves are freely produced, but no flowers are formed till the following year. Some trees take several years to recover properly from the check received during transplantation. With many kinds of tall forest and ornamental trees—say from 10 to 18 ft. in height—kinds which have not been regularly turned over or transplanted in the nursery ground, it is better to prune their tops when they are removed in proportion to the roots, which must of necessity get cut. Such topped trees are more likely to succeed than when planted with all their tops entire. The branches of many large unpruned transplanted trees frequently die, and after-pruning is necessary to

free them from dead wood. If judiciously pruned at the time of planting, the trees will make much better specimens in a given time, and save all the wood originally left. These remarks are particularly applicable to trees lifted without a ball of earth, and to those taken out of plantation thickets, where they get drawn up, and where the roots get interlaced with the neighbouring specimens.

I have not tried the effect of July and August transplanting on deciduous trees, where all the soil had been previously removed from their roots. In such cases I should say that if freely divested of many of their branches and the shortening of others, and all injured roots properly swathed or out, success may attend the operation; but in no case need success be expected if all the leafy branches are left on. When large deciduous trees, say with stems from 2 to 3 ft. in circumference, are to be lifted, and one year is given for preparation, viz., the opening up of a trench all round during the previous year, varying according to the size of the tree, the roots properly cut, and the trench filled up again; when the season for lifting takes place, all the branches should be partially removed and shortened, as shown in the annexed representation (fig. 1), such mutilated stems can be transplanted with impunity. No doubt such specimens are disfigured for a time; ultimately, however,

Fig. 1.

Fig. 2.

they push out and make good trees, which is preferable to the system of preparing the roots one year, and removing them without any of the branches being lopped. The soil in all these cases is generally taken from the roots, so as to enable the stems to be lifted, and laid over on a janker, or some other similar contrivance, for the purpose of removal. Several large specimens known to me treated in the branch-pruned way are now fine, healthy, luxuriant-growing trees, while many large unpruned specimens are either dead or partially decayed. This same operation of topping, branching, and root-cutting also equally applies to hedges, both evergreen and deciduous; while being transplanted they are, no doubt, disfigured for a time, but ultimately they break out all over and gradually thicken up, which would rarely be the case if lifted and planted without any cutting whatever. After cutting, the stems can be regularly arranged, which is difficult to do satisfactorily when transplanted without these preliminary operations. Young hedges may be successfully treated without the cutting alluded to, while with medium and old hedges such an operation is absolutely necessary. The success attending severe pruning is very marked in the case of recently-cut stems placed in the ground for the purpose of training Roses on or other flowering climbers. I have seen stems of Oak, Elm, and Ash, about 15 in. in circumference, dug up even during the months of May and June, all the roots cut off below

the surface of the soil, as well as their tops (fig. 2), and all the side branches, leaving the stems about 10 or 12 ft. in height. No matter in what season this work is done roots will be produced soon after the stems are in the ground; buds will be produced which afterwards become branches. Pillars or supports of this kind are less liable to rot or get blown down than dead wood pillars would be; of course young branches, when formed, must be regularly pruned off or shortened to prevent them interfering with the climbing plants planted against them to receive support.

Since writing the foregoing I have had some conversation on the subject with my friend Mr. P. S. Robertson, who has had great experience in planting, and in all landscape gardening operations. In one of those villa residences in the neighbourhood of Edinburgh, the laying out of which was entrusted to him, a site was selected to build a new mansion; on the proposed ground stood a large Pear tree, about forty years old, with a stem 3 ft. in circumference, and which was a favourite with the family on account of the produce annually supplied by it. As the work was commenced at Midsummer, this Pear tree had to be lifted and removed to another part of the garden. While the operation was going on every leaf was cut off, and the tree carefully planted. During the following year leaves were put forth, but no flowers or fruit were produced, now this tree is in full vigour, and annually produces good crops. As this favourable result is entirely attributed to the cutting off of the leaves, it may serve as a hint to parties wishing, or rather obliged, to remove trees at seasons not generally practised, and may apply equally well to forest and ornamental, as well as to fruit trees. This sudden cutting off of the leaves prevents the sap being carried off by them, and thus reserves it for the nourishment of the stem, and for perfecting the dormant buds. Cutting off the leaves of certain plants is by no means new; but I never saw the practice applied to large fruit trees as alluded to by Mr. Robertson. Many years ago, while in charge of the Caledonian Horticultural Society at Edinburgh, we frequently had occasion to send portable deciduous trees and shrubs, also rare plants, fruit trees, and Gooseberry bushes to New Zealand and other distant foreign countries. In all cases I removed their leaves before packing, and generally found that such, after a long voyage, arrived in better condition for growing than those packed with all their leaves on. Now that steam navigation is employed, and these long voyages are in consequence shortened, such plants can be sent with safety after their leaves are naturally off in autumn. I may state, that in all cases the roots were placed at each end of the packing-box, firmly secured by layers of Sphagnum Moss, while their tops were free in the middle.

FANCY PRIMROSES.

Though much has recently been written relating to the properties, culture, and improvement of *Primula acaulis* and *elatior*, much more remains to be added to our present limited knowledge of the capabilities of these beautiful and tractable plants before the subject will be nearly exhausted; for, at the present time, there is probably not a single variety of Primrose in cultivation that is not susceptible of great improvement, or one that meets the requirements of a perfect florist's flower, which requirements are, with reasonable care, quite attainable. At present I am not sufficiently cognizant of the results of my second year's experiments to enable me to refer to them with any amount of certainty; but, at some future period, I trust to have the opportunity of showing how very easily good seedlings may be raised. I propose, therefore, for the present, to confine my remarks to the power of pollen, as illustrated by my first year's experience. Late in the spring of 1874, I was so fortunate as to obtain from Mrs. Bower, of Hackness, *Primula acaulis* Vesuvius, which grand variety was raised by that lady. Perceiving that it was capable of introducing a new strain, it was decided to make the most of it, but, unfortunately, the season was too far advanced to permit me to procure suitable varieties to seed it on to; therefore, it was necessary to rest contented with such plants as could be obtained. These com-

prised one yellow-marbled Polyanthus, one silver-chain Polyanthus, and one scarlet Polyanthus, three dark varieties, all of which were thum-eyed and of fair form and substance; they were carefully potted and placed in a cool greenhouse close to the glass. After removing the fully-expanded flowers, those that were about half-matured were cut open to the bottom of the calyx to extract the immature pollen, and at the proper time that from Vesuvius was applied. I am aware that Lecoq and other leading authorities are of opinion that seedlings, with many exceptions, resemble the seed-bearing parent both in colour of flower and habit of plant rather than those of the male; but my own experience is directly at variance with this opinion, and for a long series of years it has been my invariable practice to trust exclusively to pollen for any property required, and I may add that where suitable plants were obtainable I cannot remember a single instance of failure in obtaining any desired feature, at the same time it is only right to admit that I have possibly travelled on the longest road to attain my object. It is impossible to give a very correct idea of the markings and colours of the 350 seedlings that I have raised; many were thrown out so soon as they flowered, and more still were given away, while those that were retained on trial have been so much injured by the larvæ of the otiorynchus sulcatus that but few of them are at their best. I think I may safely say that there were not ten true Polyanthuses, or the same number of true Primroses, while the remainder were intermediate. Regarding colour, a few were straw or primrose, about a dozen were pure white, a small proportion were dark shades of colour, and a large number were more or less like Vesuvius. At present, it is difficult to decide on the merits of these seedlings, some of them are of good form, size, and substance, and possibly a few may be worth keeping for a season or two, though I trust that the best of them will shortly have to give place to better varieties, for at present they can only be considered as the first step towards obtaining fancy Primroses.

A. CLAPHAM.

Ramsdale Bank, Scarborough.

GRAPE HYACINTHS.

Most of the Grape Hyacinths are now in full flower, and many of them are very desirable in the mixed border. Muscari botryoides is a well-known and deservedly favourite bulb, and has a distinctly dressy appearance from its little white teeth on its blue globose clusters. It grows about 9 in. in height, and is, therefore, very suitable for the front line of the border. The varieties *M. b. pallidum* and *M. b. album* are very distinct, and are even more beautiful, the former has pale sky-blue clusters, and is at the present time one of the prettiest ornaments blooming in the garden. *M. Heldreichii* resembles *M. botryoides*, but is finer, both by reason of its longer spike of flowers and from its larger size; it is now in full bloom. The best-known, perhaps, of all the species is the old *M. racemosum*, with its dark purple clusters and its strong small of Plums. Its leaves are long and weak, almost lying prostrate on the ground, whereas in *M. botryoides* and its varieties they stand boldly erect. We may still find *M. racemosum* in old cottage gardens, as it is seen in some few places, growing apparently wild, but no doubt has only escaped from some adjacent garden. It will hold its own anywhere, and, if permitted, wander all over the mixed border, growing like a weed and in any soil. This plant has a near relative in *M. comutatum*, with blue flowers darkening by degrees into purple (whence its name). Quite distinct from any of the foregoing is the Feather Hyacinth (*M. comosum monstrosum*), growing a foot or more in height; its flowers, of a beautiful mauve colour, bear a close resemblance to purple feathers, being cut into clusters of wavy filaments. Though, comparatively speaking, this species is now seldom seen, it is in every way qualified for a place in a collection of hardy flowers. *M. comosum* should not be omitted from the same collection, though it is not likely to be grown for its beauty. It has flowers in clusters, of a dirty yellow hue and very inconspicuous, but amply atones for its shortcomings in this respect by its delicious fragrance. Another sweet-smelling Muscari is *M. luteum*, the flowers of which fade by degrees from a dull purplish hue to one of a clear yellow. *M. armeniacum* I have not yet tried, but, from all accounts, it must be one of the best. There are several other varieties offered in catalogues, but I believe the best are the ones I have mentioned above. Though coming from the south of Europe they are all perfectly hardy, and will grow in any position in ordinary garden soil, which should induce everyone to cultivate the different species and varieties of Muscari.

OXON.

The Mounds in Hyde Park.—Mr. Pease called attention in the House of Commons, the other evening, to the mounds of earth now being erected on the south bank of the Serpentine; he moved that the mounds at present being erected there are unsightly, and will, when planted, be detrimental to the picturesque character of Hyde Park, and ought to be removed. The debate was adjourned for another day. There is no doubt that from the point of view of landscape effect the making of these mounds is a great mistake. The view is interrupted, and will be wholly shut out, if the trees be allowed to grow; the pleasant slope of turf that spread from the "Row" to the water's edge is destroyed.

Forcing Lilacs.—Will you kindly inform me whether there is any difficulty in growing and forcing Persian Lilacs, as my gardener never has more than three or four wreathed blooms on a plant. There cannot be any art in the culture I think, or you could not buy them for the small sum of half a franc in the flower markets in Paris.—P. J. N. [A source of failure with Lilacs is caused by annually taking up young unprepared plants for forcing. They must be established and furnished with plenty of flower buds, and then the rest is easy. There is so much "art" in the forcing of Lilacs that some people devote their whole lives to it and perhaps one or two other subjects. It is inconsiderate to expect a private gardener, who is concerned about many things, to rival a market grower, who devotes his whole time, and perhaps all needful means, to the culture of a single plant.]

Increasing the size of Cut-back Pot Vines.—Canes in pots, grown from the previous year's roots, generally make a foot or two of strong wood at the bottom; but, as they ascend, they become smaller, and often at 4 ft. and 5 ft. from the pot are no thicker than a Wheat straw. This is much against Vines fruiting well, but they may be had as thick at the top as at the bottom, by stopping the leading shoot whenever it shows the least indication of getting smaller. Vines treated in this way are a week or two longer in attaining their full length; but this is no detriment, considering what is gained through the delay. Vines raised from eyes have not generally the same fault.

—J. MURR.

The Dwarf Aubinel Peach.—The "Revue Horticole" of the present month gives an account of the Dwarf Aubinel Peach, which merits the attention of all Peach-growers. This Dwarf Peach is a bushy, round-headed, vigorous tree, with upright branches, which are thick, short, and numerous. The flowers are large, and of a bright rose-colour. The fruit is of a pale yellow, clouded with red, and is of exquisite flavour. It ripens in Paris about the end of September, in a sunny situation. When the fruit has nearly attained its natural size, it ought to be well cleared from the leaves about it, the abundance of foliage being very great. It is of such small dimensions, that it may be grown in pots, and even placed on the dessert-table, or it may be cultivated in borders like Gooseberry bushes. This valuable addition to the fruit garden is due to M. Aubinel, nurseryman, Grenade, Haute-Garonne. It may be mentioned that the seedlings resemble the parent plant in every detail.

"Sweets."—The public—especially the poorer classes—are cautioned in "Chamber's Journal" against buying jams labeled "Family Preserve," "Royal Jam," "Fruit Preserve," or "Household Jam," which are made up chiefly of rotten, maggoty, and unsaleable Figs, together with bad Plums and the sweepings of warehouses. Greengage jam is frequently coloured with copper, and marmalade is often adulterated with Apples and Turnips. Copper enters largely into much of our most tempting preserves, owing to the copper vessels in which they are prepared. The highly coloured green bottled fruits and tinned vegetables are nearly all contaminated with copper to a greater or lesser extent: it is purposely introduced not as necessary to the preservation of the fruit and vegetables, but to retain the bright green colour considered so essential to the look of the articles. The English purveyor, like the Chinese, finds that the best looking things, coloured at the expense of a little poison, demand the readiest attention and the quickest sale.

How to get rid of Tree-stumps.—Gen. Colquitt, of Georgia, in a recent address, said:—To remove stumps from a field, all that is necessary is to have one or more sheet-iron chimneys, some 4 or 5 ft. high. Set fire to the stump and place the chimney over it, so as to give the requisite draught at the bottom. It will draw like a stove. The stump will soon be consumed. With several such chimneys, of different sizes, the removal of stumps may be accomplished at merely nominal labour and expense.

— In the autumn, bore a hole 1 to 2 in. in diameter, according to the girth of the stump, vertically in the centre of the latter, and about 18 in. deep. Put into it from 1 to 2 oz. of saltpetre; fill the hole with water, and plug up close. In the ensuing spring, take out the plug, and pour in about 1 to 2 gills of kerosine oil and ignite it. The stump will smoulder away, without blazing to the very extremity of the roots, leaving nothing but ashes.

NOTES OF THE WEEK.

— The old Pelargonium, or as it was commonly called, Geranium Gauntlet, is still the most popular kind in the London market. Mr. Bennett, of Rabley, has a wall covered with this variety 215 ft. long by 8 ft. high; it is now coming strongly into bloom.

— PERHAPS the finest of all flowering trees for cities and districts that suffer from a smoky atmosphere is the great flowered Magnolia conspicua. Trees of it on the warmer soils in suburban London are now strikingly beautiful.

— NUTTALLIA CERASIFORMIS is the name of a free-flowering but not showy shrub, with white flowers, which are remarkable for affording us the true Hawthorn scent early in the year—May blossoms in March, in short. It grows and flowers very freely in Mr. Parker's Nursery, at Tooting.

— ERYTHRONIUM GIGANTEUM of Western America is now in flower in Kinghorn's nursery at Richmond and in other gardens round London. It is not by any means so pretty a plant as the Erythronium of our European Alps and gardens. It may, however, merit culture from its distinctness.

— As we write the orchards in the valley of the Thames begin to show their buds and flowers, and in a few days the recently blackened trees will be clouds of white Plum blossom. For some weeks to come London market gardens and Kentish orchards, and, indeed, orchards and fruit gardens in many northern lands will be, for the time, our best flower gardens.

— ONE of the most offensive nuisances and air-poisonings is caused by the laying down of the wood pavement, now becoming common in London. This is all the more to be regretted because the wooden pavement is not so lasting, or on the whole so satisfactory as the best asphalt. For cities, so far as our present knowledge goes, nothing equals the asphalt. When kept free from dust, &c., by aid of the hose, it is also most conducive to the purity of the air and consequently of health.

— MR. J. MEEHAN fancies that in cold countries, at least where the Eucalyptus will not grow, marshy districts would be improved by the planting of vigorous hardy Conifers and other evergreen trees. We have long thought so, too. If malaria be caused by a large area covered or partially covered with decaying vegetation, it is reasonable to suppose that the substitution of abundance of living trees, withdrawing redundant moisture from the soil, and perhaps charging the air with aromatic vapours, will produce a very different and healthy condition of both air and soil.

— The beautiful dwarf Cypripedium acule, of the North American woods, is now one of the most charming plants in London Orchid-houses. Although the plant is very dwarf (3 in. high) the flowers are as large as those of the tropical kinds, while the colour is even more beautiful. These little plants, flowering in March in English hot-houses, have, as yet, made few or no fresh roots, but both flower and leaf are well sustained by the nourishment stored in the roots last year in their native woods. Although now to be seen in Mr. Bull's hot-houses, it may be as well to add that the plant is as hardy as the Lily-of-the-Valley. Perhaps the most interesting way of growing it in Britain would be naturalised in woods with a sandy or peaty soil.

— The gorgeous mass of Daffodils in some of the nurseries round London may now serve to point out the value of these plants in garden scenery, apart from their high individual beauty. Fine collections have been formed; it is now for the public to treat the stronger and nobler kinds with a view to their effect in the wild garden and pleasure ground, as well as in the borders or bulb-beds. These remarks occurred to us on seeing the rich masses of the variety of Narcissus bicolor, called Horsefield, and the Butter-and-eggs Daffodil, among many other kinds, in Mr. Ware's Nursery, at Tottenham. No tropical flowers can do more for their own woods than these and like plants may do for our gardens in spring, and to them the kind of spring matters little. We believe that as the public become familiar with the merits of these plants, they will be used to an extent they never were before since the days of Parkinson; and mainly because, in addition to resuming again the culture of these flowers, we have wider ideas as to their use, and do not restrict them, as in old times, to the border. The wild garden round country houses should show crowds of them, as many of the finest kinds are as hardy as an easily grown as any native weed.

— A BEAUTIFUL new Odontoglot was shown on Wednesday last at South Kensington. It has smooth compressed one-leaved pseudobulbs closely arranged along creeping rhizomes, the leaves being of a deep glossy green colour. The flower-spikes is slender, about 18 in. in height, and branched, bearing from twenty to thirty pure white, purple-spotted flowers; the sepals and petals have undulated mar-

gins, and their apices are drawn into long tapering points. The lip is yellow at the base, boldly streaked with rich dark brown, and the crest is whitish and two-lobed. The flowers may be likened to those of *O. mævium*, but are fully three times larger than those of that species, the white being purer, and the purple spots fewer and larger. It is quite distinct as a species, and when more plentiful cannot fail to be extremely popular. It is one of Mr. Bull's recent introductions from Ecuador, the specimen shown, and to which a first-class certificate was awarded, having flowered in the collection of Mr. Spencer Brunton, of Beckenham.

— The old double Primroses, supposed to be getting scarce, and certainly so in private gardens, are now sent in considerable numbers to the London market, both in the form of cut flowers and plants.

— VERY fine Hydrangeas, in pots, may already be seen in Covent Garden, though in small batches. They do not seem quite in their place among spring flowers.

— MESSRS. WARNE AND Co. will in future publish Mr. William Paul's books on gardening, and this week that firm has issued "Villa Gardening," which embodies in the form of a series of letters very good advice. The woodcuts, however, are unworthy of the book.

— COX'S ORANGE PIPPIN is a novelty in April; we have just received a very fair sample from Messrs. Cox, of Donington, near Spalding. The fruit was somewhat shrivelled, but of a high and delicate flavour. The presence or absence of a popular fruit in Covent Garden is not always evidence of its keeping qualities. Probably our Apples could be kept much longer than is the rule at present, if fruit rooms were made to preserve a very low and equable temperature. Frequently they are so constructed as to be influenced by every slight change, and to preserve a warm temperature; a great deal depends on locality, too, as regards the keeping of fruit.

— EASTER BEURRÉ is still the best late Pear known. We speak of the fruit as it comes to the London market from France at this season. Very early in the year the flavour is not so good as at present. Easter Beurré, as grown in England, ripens much earlier, and has not the same flavour; but grown on white walls, as in France, it might prove valuable in the southern counties. Fruit-raisers, wanting an aim, might do well trying to get a fruit as good as Easter Beurré and suited for our climate. The finest fruits of this variety we have ever seen were from California. If they would keep as these French Pears do, it would pay to send them all the way across the plains and ocean by express. Probably, however, the sunny plains would produce a thoroughly-matured tender-fleshed fruit that would soon decay; the cooler foot hills should give fruit more likely to last till Lent.

— A SEED and nursery trade association has lately been formed in Scotland, the main objects of which are:—1st. To hold an annual meeting of the association, at which members may bring forward any matter of importance, notice of the same being given to the secretary one month before the said meeting. 2nd. That it shall be competent for members to lay before the committee through the secretary any case in which they may feel themselves aggrieved, or laid open to vexatious claims in respect of complaints of the growth of seeds, failures of crops, &c., and the committee shall advise as to the best course to pursue, and (if need be) obtain counsel's opinion in the case. 3rd. To use all endeavours to check and put down the vending of adulterated and falsified seeds of all kinds, either in this country or abroad. 4th. To watch over the interests of the trade in any legislation that may be proposed affecting the same." The annual subscription has been fixed at one guinea. Mr. David Roughhead has been appointed chairman, Mr. David Cross, vice-chairman, and Mr. R. T. Mackintosh, secretary and treasurer for the ensuing year.

Starting Pot Vines Early in Autumn a Disadvantage.—There can be no doubt that if Mr. Temple's plan of retarding pot Vines for early fruiting be successful, it will be a great advantage, inasmuch as in many places a number of Vines have to be got ready for placing in their forcing quarters by October or November; Vines started into growth then, or even a month later, have a very short period of rest, and, therefore, they never start so freely into growth as Vines do in spring; the buds are long in "moving," the leaves are still longer in appearing, and a good many of the buds never start at all. Therefore, it would be a profitable plan to be less hasty in starting pot Vines in autumn. Some affirm that pot Vines started in Christmas are as far forward in April as those started on the 1st of November; and while the latter are only provided with a branch and bunch here and there, the former produce a heavy crop. It is pretty well understood that Vines dislike being started into growth in autumn; six weeks or two months longer rest is of material benefit to them, and no disadvantage in the end so far as earliness is concerned.—J. MUIR.

THE KITCHEN GARDEN.

WHITE CABBAGE BUTTERFLY.

(PIERIS RAPÆ.)

THE accompanying woodcut represents the smaller Cabbage butterfly, which is very common in this country. It closely resembles the larger species, and if there were nothing but the difference in size to distinguish the one from the other, it might be difficult to say that it was not a stunted variety of it; but the eggs are different, and so are the caterpillar and pupa, and their differences are constant, so that there can be no doubt as to the species being distinct.

The egg of the large white Cabbage butterfly is oval, and is deposited on the under sides of the leaves in clusters of thirty or forty together; that of the present species is more attenuated at the point, and is likewise deposited on the under sides of the leaves, but singly. Its caterpillar is green, with a yellowish stripe down the back and along each side, and it is so closely covered with hairs as to seem velvety. The caterpillar of the large white butterfly is bluish-green, and has a similar, though more decided, arrangement of colour, but it is sprinkled over the green parts and along the lines of yellow with comparatively large black dots. The chrysalis of the latter is pale green, speckled with black, while the chrysalis of the smaller species is pale flesh brown freckled with black. There is a third white Cabbage butterfly with which this may be confounded, *Pieris napi*, or the green-veined white, a kind readily distinguished by the veins on the under side, and more especially those of the lower wings being edged with green scales. All three species feed upon the plants of the Cruciferous Order, such as Cabbages, Turnips, and Rape, although by no means exclusively; many others of our garden plants, such as Mignonette, Nasturtium, &c., also suffer from them, but not to the same extent. No better remedy or alleviation seems to have been found for this destructive insect in this country than hand-picking; but we find that in America, to which country the species has of late years extended, other measures have been found effectual. There, salt sprinkled over the Cabbages, &c., is the common remedy, but the following plan has been recommended by a Mr. Quinn to the New York Institute Farmers' Club. He says—"I have tried no fewer than fifteen different decoctions, and find the best result from the application of a mixture composed of twenty parts of sulphate of lime, one part of carbolic powder, and three or four parts of quicklime. This I sprinkle in small quantities upon the leaves and parts affected, making the application early in the morning before the dew is off or

after a shower. Frequent repetition is sometimes necessary." The introduction of this species into North America and its spread there is an interesting chapter in its history. It was unknown in the New World previous to 1859, when for the first time it was taken at Quebec. In 1863 it was captured there in larger numbers. It is supposed to have been introduced in the egg stage. As already said, the eggs are deposited on the under sides of the leaves on which it feeds, and the hypothesis is that some rapid steamer from Britain had brought with it a supply of fresh Cabbages, and had come so quickly that the store was not exhausted before it reached Quebec—that the remaining Cabbages were thrown out as refuse, or given away on arrival—that there were eggs upon them which hatched, and the emerging larvæ, after making a start of growth on the old Cabbages, unfortunately found themselves near fresh plants to which they made their way and on which they fed and flourished. The climate was suitable to them, although the cold makes greater havoc with the chrysalids there than here, and they soon began to spread all around. In 1864 they had spread 40 miles on every side of Quebec. In 1866 they were taken in the northern parts of New Hampshire and Vermont. In 1868 they had advanced still further south, and were seen near Lake Winnepesaukee, and in 1870 they were taken around Boston, Massachusetts, and a few stray specimens in New Jersey. In and around Hudson City and West Hoboken they were very abundant—so much so, as one observer said, that after the butterflies came out, the Cabbage garden looked as if there was a small snow-storm going on. In 1871 they destroyed £100,000 worth of Cabbages in the vicinity of New York alone. In 1874 they had reached Washington and spread into Virginia. The insect, however, does not seem to have made an equally rapid progress to the west, but in 1872 it had reached as far as Belleville and Trenton, Ontario. In 1873 it reached Port Hope, and by 1874 it had spread all over Ontario. One curious

The Lesser White Cabbage Butterfly.

circumstance attending the invasion by this butterfly is that in many parts of the country which it has colonised a new variety of a bright sulphur yellow, called by Mr. Scudder *P. novangliae*, has made its appearance. American entomologists are still in doubt whether this is a climatal or a food change. It has been noticed by some of them that when the larvæ, hatched from eggs laid by white individuals, have been fed upon Mignonette, the produce has been this yellow variety; whether the food was the cause or only an accidental coincidence is still under consideration. We do not know whether the experiment of rearing the larvæ of *P. rapae* entirely on Mignonette has been tried in this country, nor with what success, although, from the above facts being well known to our

English lepidopterists, it seems almost a foregone conclusion that the experiment has been tried. Perhaps some of the readers of *THE GARDEN* may be able to enlighten us on this point.

A. M.

FORCING ASPARAGUS IN OPEN-AIR BEDS.

The forcing of permanent beds of Asparagus, although by no means new, does not appear to be so generally adopted as might be expected. That a greater number of heads may be cut from a given space under glass, by lifting well-established crowns and planting them thickly on a gentle bottom-heat, I readily admit, and for the earliest supply—from November until the beginning of February—I have not yet found, in all respects, a better plan; but for a supply during February and March permanent beds, gently forced, will yield Asparagus for a number of years quite equal to that produced by summer beds. The beds from which we get our February and March supplies are well established; they are 5 ft. wide, and are surrounded by a brick trench 2 ft. wide and 3 ft. deep, the wall next the beds being pigeon-holed. Over the bed is a movable span-roof, made in 16 ft. lengths for four lights each side, 4 ft. wide. These beds are dressed with rotten manure in November when the trenches are emptied of decayed forcing material, and re-filled with leaves and stable manure in proportion to the time when they are required to come into bearing. The earliest division we fill principally with manure, and keep it constantly replenished, in order that the heat may not decline; nor must it be allowed to get too hot, as the more gradually the growth is excited the finer will be the produce. The lights, which are put on early in December, are covered with litter during frosty weather, uncovering on the south side during every interval of sunshine, to which, in fact, the latest division (that comes in during March) is indebted for nearly all the heat it gets, the trenches being only filled with leaves. Under these conditions the growth is natural and gradual, and not subject to sudden fluctuations of temperature, and, owing to the roots being thoroughly established and gently excited into growth, the produce is tender and highly flavoured. In late springs, like the present, such contrivances are invaluable, as regards maintaining a good supply of this favourite vegetable, until it is plentiful on open beds. When the root is removed and cutting discontinued, a good soaking of liquid manure starts the young growth afresh, and, by shifting the course of forcing, so that the earliest bed of one year is the latest the next, such beds may be kept productive for a number of years. The movable roof, too, need never be idle; it may be re-erected on a bed of coal ashes, and used for hardening off bedding plants; while later in the summer it may be elevated on brick piers, for sheltering such plants as suffer from exposure to heavy rains. In autumn we strike most of our variegated and tender kinds of Pelargoniums under its shelter—in fact, the uses to which it may be put are unlimited.

JAMES GROOM.

Henham.

SEAKALE AND ITS CULTURE.

THIS, though a delicious and wholesome vegetable, seldom finds a place in the villa garden, and the middle and lower classes are nearly wholly unacquainted with it. By a little forcing it may be had in perfection from the end of November or the first week in December till the end of May—a period embracing the whole of what are termed the dead months. Vegetables as a rule are not improved by forcing, but Seakale forms an exception, the forced shoots produced at Christmas being more crisp and delicate than those grown out-of-doors. While most vegetables are spoiled by over-cooking, this, on the contrary, can scarcely be boiled too much; and when it is well boiled, it should be thoroughly drained, and allowed to remain a few minutes before the fire, in order that a further portion of the moisture belonging to it may be evaporated. Seakale grows plentifully on our western shores, and from very early times people residing near the coast have been in the habit of watching when its shoots and leaf-stalks have begun to push up the sand and gravel in March and April, in order that they might cut them off underground and boil

them like ordinary Sprouts. One authority states that it was grown in quantity in this country and sent to the Continent more than two hundred years ago. But, be that as it may, it was not much known about London until the middle of the last century, when it was cultivated by Dr. Lettson at Camberwell, and it was through his instrumentality that it was brought into notice in the London markets. It has now become a common and almost an indispensable vegetable in all gentlemen's gardens, and when properly dressed and served up like Asparagus, it is very little inferior to that vegetable.

There are various modes of propagating Seakale. Formerly it was raised from seed, but this, at best, is a tedious process, and requires a long period of patient waiting before the produce is ready for use. When gardeners of the old school sowed their seed, they never expected to cut Seakale fit for food for three years afterwards. Even now some of the London market gardeners raise their plants from seed. When this plan is adopted, a piece of ground should be selected and prepared by deeply digging and manuring it. A bed or beds (according to the quantity required and the length of the beds) 4 ft. wide must be formed; draw the drills about 2 in. deep, three to a bed, and 15 in. apart, and sow the seeds pretty thickly. They will require no care the first season beyond keeping down weeds. When the plants are twelve months old they must be lifted, cut into 6 in. lengths, preserving the crowns, and throwing the other parts of the roots away. These prepared plants must be planted at once, and will make strong stools for forcing in the autumn. The great objection to seedlings is that they occupy the seed-bed for one entire season without any profitable return. The most modern way of increasing Seakale is by means of pieces of the root which are cut away when lifted for forcing. Every inch of Seakale roots will form a plant the same as bits of roots of Horseradish or Dandelion. These pieces of roots must be taken care of and put into a heap in a shed until the whole plantation is lifted for forcing. The best must then be selected; cut up into pieces about 3 in. or 4 in. in length, and laid in a heap by themselves. The remainder may be either burned along with the prunings of fruit trees or consigned to the rubbish-heap, where they should lie until there is no possibility of their starting again into growth. When the cuttings are prepared they should be buried temporarily as soon as all the roots have been taken up. This may be about the end of January or early in February. By the end of March or early in April these roots will have pushed several eyes, and emitted a quantity of white feather-like rootlets. The top and bottom ends of all the cuttings may now be easily discovered, and all the eyes, except the strongest one on the top, should be rubbed off, afterwards they should be dibbled into the ground with the head end upwards.

Although Seakale may be taken up and forced at mid-winter in any situation in which there is a temperature of 60°, still there must be a plantation left for producing the Kale in the open ground. In many gardens this is done by covering the crowns with pots or boxes made for the purpose, or they may be hooped over with Hazel sticks, and covered with a mulching of litter to exclude light; in fact, in many places the bulk of the Seakale is forced in this way. In making a plantation to furnish heads without being taken up, it may either be formed of one-year-old plants, or of sets of cuttings which will make equally good stools. The plants raised from seed give trouble in reducing the number of their crowns; whereas sets, if properly made and treated, give hardly any, and in one year make almost as good crowns as real plants do. In planting, three plants should be placed in patches in the form of a triangle, 2½ ft. from each other, in rows, and the rows should be 3 ft. asunder. The ground may be intercropped with Lettuce or Cauliflowers, which should be removed before they interfere much with the Seakale. When planting with the intention of taking up the roots in autumn, they should be planted in rows 2 ft. apart, and 9 in. asunder in the rows. The plan of forcing Seakale with fermenting materials, for very early use, is growing somewhat out of date. When it is required by the end of November, or the first week in December, the best crowns and those that are best ripened should be taken up; those are the most suitable on which the leaves wither the earliest, and these should be selected, as it is diffi-

cult to get Seakale to start early, notwithstanding its being the easiest of all vegetables to force. The crowns being in readiness, a hot-bed, in the absence of a Mushroom house, should be prepared and covered with a frame, and a few inches deep of soil should be placed within the frame, in which the roots should be planted, and that as thickly as they can be conveniently stowed together. A one-light frame, 5 ft. by 4 ft., would supply Seakale for a large family. The frame may be covered either with mats or straw hurdles, the points being the retention of heat in the frame and the exclusion of light. When required very early, the heat should be kept up to 65° or 70°. A few roots should be introduced at intervals of two or three weeks, according to the demand. In order to have natural Kale, as it is called, we cover up the crowns in the open ground about the end of March, or just before they begin to bush, with tubs or pots, or anything that will keep them in the dark. From those crowns last covered we have a supply to the middle or end of May. For the last cutting in the market gardens the crowns are covered with soil from between the rows to the depth of 6 in., and as soon as the point of a shoot is discerned above the ridge it is fit for cutting. The soil should be drawn away with a spade and the shoot out over close to the crown. When the Kale is all cut the ridges should be levelled down, or if pots have been employed they should be removed, the ground forked over, and the space between the rows filled with Lettuce. Q. R.

NO MORE HOLLOW OR SPONGY CELERY.

The following system of culture, properly carried out, will be found to meet Mr. Thomson's wants (see p. 255).—In the first place, the seed must not be sown too thickly, and as soon as seed leaves are formed, thin out the smallest plants, leaving the strongest an inch apart, and keep them close to the glass, in order to prevent them from becoming drawn. As soon as the plants are fit to handle, prick them out 6 in. apart on a bed prepared for them in the following manner.—If for an early crop, employ a frame set on a slight hot-bed, on which place a compost consisting of equal parts of well-rotted manure and soil, mixed together and made quite solid to the depth of 4 in. When finished, the surface of the bed should not be more than 6 in. from the glass, as the frame can be gradually raised as the plants increase in height. Ventilate early in the morning, when the weather is favourable, and close early, slightly damping the plants overhead. As the season advances, ventilate more freely by degrees, and after a time the frame may be lifted off altogether, paying every attention to watering when required. In preparing the trenches, a line mark should be drawn every 3 ft. apart, according to the number required; take the soil one spade deep out of every other space, and fill up with well-rotted manure, mixing it with the second spit of soil, and leaving a hollow up the centre in which to place the plants. Owing to Celery being a surface-rooting plant, it is best to make the trenches tolerably wide, as, in that case, the soil can be levelled back, with the exception of 18 in., which should be left for the Celery row; the intervening spaces can be prepared for other crops, but care must be taken that they do not interfere with the routine culture required for the Celery, or more loss than gain might be the result. Four or five days previous to planting out, run a sharp knife down the centre of each row the depth of the compost, and do the same cross-ways, finishing off with a thorough watering, which closes the openings and prevents any check to the plants; in four or five days' time a spade may be run under the plants, which may then be lifted, placed carefully on a hand-barrow, and conveyed to the side of the trench, in which they should be planted 10 in. apart and 1 in. deeper than they were before they were moved, placing the soil firmly round each plant. When completed, give the whole a good watering to settle the soil, and cover the surface with lawn-mowings or half-decayed leaves, which will prevent evaporation and encourage the growth of surface-roots. Should the weather be dry as the plants progress, give them a good watering every ten days or so with clear water, and if manure-water be used, let it be weak, for if given too strong it destroys that delicious

flavour and crispness which is so highly appreciated in first-class Celery. A piece of soft matting should be tied round each plant, so as to prevent the weather from breaking down the leaves and the centre from becoming green. Earthing-up should be done gradually and carefully in order that the plants may not be pressed out of shape, and when the soil is in a friable condition. Pinch off the tops of the leaves and raise the matting, as when the foliage gets yellow the Celery becomes discoloured. The cause of Celery growing hollow or spongy is due to over-feeding with rank manures, and sudden checks cause it to run to seed. From the time the seed is sown until the last earthing-up, avoid sudden checks and rank manures. JAMES SMITH.

Watercure.

PARSLEY ALL THE YEAR ROUND ON ALL SOILS.

Though the culture of Parsley is very simple, yet to have an abundant supply of it all the year round is often attended with some difficulty, where spare lights are not available for this purpose, and especially in low-lying, moist situations. On cold, stiff, retentive soils, it frequently dies off. It can be grown successfully in any light, rich ground, that has a dry porous sub-soil. To meet a constant demand all the year round, three or four successive sowings should be made from February to May. The seed should be sown in very shallow drills, and be very lightly covered. When the young plants are up and large enough to handle, they should be thinned to 6 in. distance in the rows. The first sowing or two will furnish leaves all through the summer and autumn, and with care and a little management all through the winter, but I prefer and would recommend sowings in May for a supply in winter. A dry border should be chosen for it, and where there is a south wall a little sown at the foot of it will always be useful in spring. Before severe frosts set in, ample provision should be made for thoroughly protecting a portion sufficiently large to furnish a supply of leaves during several weeks' frost. The coverings should only be put on in frosty weather; and in mild, open weather, the plants should be exposed. The difficulty of having a supply during winter is experienced where there are no spare lights available for protection, and where the soil is of a heavy, retentive nature. Many ways will occur to an intelligent mind to meet these difficulties. Where the soil is unfavourable, a site should be chosen in some sheltered part of the garden, and a bed should be prepared specially for it, by putting a quantity of stone and brick rubbish at the bottom, and on this some soil suitable for the purpose. A sowing made on this towards the end of May, if carefully attended to during the summer months, in thinning the plants and picking off any luxuriant leaves that may be produced, will furnish a supply during the winter, provided it has some protection from frost. Experienced gardeners know the importance of having a good supply of Parsley all the year round, and generally make ample preparation to have it; but young men do not always at first starting see the importance of it, and are apt to think it only a trifling matter. It does not take up very much ground to grow a quantity of it; and it is a safe plan always to sow plenty, for then, with a little attention during the summer, and some protection in frosty weather, a supply is always assured.—"Florist."

New Zealand Spinach.—This, as is well known, is quite different from the common Spinach, but it forms an excellent substitute for it during the summer months, particularly in dry seasons, when it is frequently found to be difficult to obtain the ordinary kind in perfection. The New Zealand kind is somewhat tender, and will succumb to a few degrees of frost, but, being possessed of considerable succulence, it will resist the most intense drought, and is a useful and exceedingly wholesome vegetable, containing a considerable amount of saline matter. A bed of it should be grown in every garden where Spinach is required, and as soon as it can be got sufficiently forward to be fit for use, the sowing of ordinary Spinach may safely be discontinued. The preparation necessary for the reception of the plants, intended to form the bed, is the throwing out a trench some 5 ft. or 6 ft. wide, two spits deep, and of any desired length. This trench should be filled up with good half-rotted stable manure, well trodden down, and on this should be put the soil which has been thrown out, treading all firmly down; along the centre of the bed thus formed the Spinach should be transplanted about the second week in May, each plant being covered for a time with a hand-glass. They may be placed at a distance of 4 or 5 ft. apart. Thus planted, they will soon cover the surface of the bed, and will, during most seasons, afford an abundant supply of excellent Spinach up to the beginning of November. The seed should be

sown in a mild hot-bed about the beginning of April, and the plants, when large enough, should be potted off singly, and encouraged to grow, so that they may attain considerable size by the time they are planted out into the bed. Half-a-dozen plants will usually be found sufficient for a large bed.—P. GRIEVE, *Culford Hall, Bury St. Edmunds.*

A NEW WAY WITH SHALLOTS.

NEVER plant these under walls or hedges, but in an open exposed situation on well-prepared land that has had just previous to planting a rich surface-dressing. Make it firm by treading; this should be gone over at least twice, as, if the surface be dry, it is scarcely possible to make it too firm. Plant in rows 12 in. apart, and the bulbs should be from 6 to 9 in. asunder in the rows. In planting make shallow holes, to receive just the base of the bulbs only, with a blunt dibble; cover each bulb with a small cone, consisting of about two handfuls of charcoal rubbish passed through a sieve, to take stones, &c., out of it. This will prevent the bulbs, at the commencement of their growth, from being lifted out of the ground through the action of rain and surface stirrings. The charred rubbish will crumble away and leave the Shallots standing on the surface of the ground, in the best possible position for producing fine, heavy, well-matured bulbs. Salt and soot make excellent top-dressings for Shallots, either together or separate, and they may be applied either before planting or at any time during growth with the greatest advantage to the crop. Drought, by producing a check, often leads to the attacks of insects or mildew, or it at least makes them more susceptible to such attacks. To secure and maintain, by liberal culture, a free vigorous growth is the best antidote against the attacks of insects or disease. I have given up autumn planting, as I can obtain as good or better results by deferring it until February, or, in the case of a season like the present, until March. E. H.

Ramsey Abbey.

Keeping Potatoes for Late Use.—A well-kept old Potato is superior in every respect to most of the new ones imported from Lisbon and elsewhere; and, even were it not the case, the difference in price would compel many people to use the old ones, consequently the question of preserving the quality of Potatoes becomes important. When Potatoes are kept in buildings, no matter how closely covered with straw, the quality, after the end of March, is usually inferior; but if Plukes, or Victorias, or whatever kinds are relied upon for late use, be pitted on the north side of a wall or belt of trees, they will be found far superior to others retained in any building. Keeping them cool in a medium soil, rather damp than dry, delays growth considerably, and to this end they should be covered thickly with earth. Rooks, Red-skinned Flour-balls, and other late kinds that are usually of inferior quality, are much improved if pitted in a cool place till May. I had some last year in July that were as good as Regents usually are in December. Where earlies and second earlies only are grown, as a precaution against disease those intended for late use should be separated shortly after having been dug up from the other stock, and buried in a cool place in the earth. I think Snowflake, as a second early, will prove a valuable Potato for late use. I have just cut and planted my stock, and although they have laid all the winter thinly on a shelf, they are now as fresh and firm as when freshly dug last summer; but my impression is, that if it be desired to grow this kind free from disease, it must not be over-matured.—E. H.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Spring-planted Globe Artichokes.—These never produce good heads the same year. The best plan is merely to cut away the first stems or flowering spikes, then to give the plants manure-water occasionally, when they will throw up stems equal to those first produced.—R. GILBERT, *Barghley.*

The Winter Cherry as a Vegetable.—*Physalis edulis* is receiving the attention it deserves from some French horticulturists, and M. St. Quentin, writing in the "Bulletin" of the French Acclimatisation Society, declares the fruit to be superior to Tomatoes. It ought to be grown well, and the fruit and shoots fairly thinned before we could well judge of its merits. Being so hardy and easily grown would be greatly in its favour.

Early Peas.—Ringleader on our south border, sown on November 9th for the seventh time in succession, has withstood the late cold weather well, without the slightest protection, and is now (April 1st) reaching the stakes. This Pea, being very hardy, can be wholly raised out-of-doors, without the usual trouble attending the production of Early Peas, thus saving much time, a valuable commodity just now.—R. GILBERT, *Barghley.*

Onions (A Subscriber).—There is no better plan of fastening these in very light soil than that of rolling the beds. We have seen beds rolled quite firm, even after the plants were above ground. They afterwards grew away quite strongly, and were not injured by the rolling.

THE FLOWER GARDEN.

HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

It has occurred to us that engraved representations of the various types of hardy flowers now in cultivation given week by week as they open might be of interest to many persons now beginning to cultivate these plants; we therefore begin this week, and hope to continue our pictorial record for the course of a year from the present time. It may be remembered by some of our readers that in the year 1875 we took special pains to record all the hardy plants as they flowered in the various collections about London. The weekly entries of the very numerous species that then flowered afford useful reference to those who desire to make their gardens of hardy flowers gay at any given season. The illustrated record of the various types may be suggestive to some for whom a long list of Latin names has no attraction. Our record shall mainly consist of plants that have opened into blossom during the six or seven days preceding the date of our issue. There are various hardy plants in flower now in London gardens which we do not mention or illustrate because they have been a long time in flower, and we hope to meet them in due season before April comes again. The plants mentioned and illustrated will in all cases be hardy, and grown without protection, otherwise the record would be worthless as indicating the relations between our climate and the hardy flowers in our gardens.

The present has been a most severe spring for hardy flowers in the London district, and, till quite recently, the gardens have presented a very wintry aspect. Thus throughout March there were no such beautiful effects seen in the gardens and shrubberies as in corresponding weeks in 1875. Even the foliage of very hardy Hellebores, &c., was cut down in close London gardens by the wind in March. Some days of clear genial weather, however, have induced many flowers to unfold during the week. The Hyacinth in many hues is now bursting into its fullest beauty all round London, the oblong beds in Hyde Park being like solid masses of infantry on a review day. The showiest flowers of the week are the various double Daffodils which skirt along the upper portion of the Serpentine in crowds, and are gathered into showy masses in Barr's bulb ground at Tooting, where a variety of interesting kinds of double Daffodil are now in blossom. So, too, a number of single Narcissus opened during the week; forms and allies of the Italian Polyanthus *Narcissus* (N. *Tazetta*), varieties of the Sweet Daffodil (N. *odorus*), the graceful and pale N. *moschatus*, the small Daffodil (N. *minor*), and N. *minimus*, which certainly seems to be the smallest possible of all Daffodils. The gem among all the hardy flowers of the week that we have seen is the true old Double Crimson Primrose, in flower in Parker's Nursery at Tooting. It is like a little Camellia, only a good deal richer in colour than any Camellia yet raised. The true old blue Polyanthus is in flower in a secluded nook in the same nursery. These are plants which we hope Mr. Parker will succeed in making plentiful. A singularly pretty effect may be noticed in the same nursery, owing to the accidental occurrence of a number of Grape Hyacinths in a very large bed of the spring Star-flower (*Triteleia uniflora*). Silkiest, quaintest, and, perhaps, most beautiful flowers of the week, are the varieties of our common Pasque-flower. There is a large bed of these in the Wellington Nurseries, in which a considerable variety in the colour of the flowers may be seen. The summer Snowflake (*Leucocjum astivum*) has opened its flowers on light soils during the week, and so has the Crown Imperial, which combines the merits of a showy hardy bulb and a fine foliaged plant that disregards the east wind. *Fumaria solida* and its varieties are in blossom, and the flower-garden Tulips (mostly varieties of *Tulipa scaberrima*) have opened to the sun. Two uncommon "Stars of Bethlehem" (*Ornithogalum bœticum* and *O. mutabile*) are in flower in Mr. Barr's ground, also two *Fritillarias* (*F. tristis* and *F. tenella*). The delicately fragrant bells of the various kinds of Grape Hyacinths (*Muscari*), which come up little green spikelets, are deepening their colours, and it is interesting to notice how the odours, all of the most grateful sort, are yet very diverse in kind. Among dwarf Alpine flowers the yellow Whitlow Grass

Bulbous Fumitory.

Yellow Whitlow Grass.

Pasque-flower.

Marsh Marigold.

Early Tulip.

Double Marsh Marigold.

Drooping Daffodil.

Common Daffodil.

Sweet-scented Narcissus.

Polyanthus Narcissus.

The Crown Imperial.

Summer Snowflake.

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

(*Draba aizoides*) is conspicuous; and among herbaceous plants *Doronicum austriacum* is the most showy. In the bulb class, the modest yellow and green *Gagea fascicularis* is noticeable in the Fulham Nurseries, where also the curious *Podophyllum Emodi* is sending up its flower-stems.

DISTILLING THE BLOOMS OF FLOWERS.

IN THE GARDEN of March 25 (p. 300), F. W. C. asks for information as to the best way of distilling the fragrant essence of Roses, Violets, and other flowers. One of the highest authorities on the subject, Mr. Eugène Rimmel, tells us in his charming work, "The Book of Perfumes," that, with the exception of Lavender and Peppermint, our unhappy climate will not permit of flower growing for perfumes at a profitable rate on a large scale. Where the object is to utilise flowers that would otherwise be wasted, distillation may be practised on a small scale with pleasure and profit. A quart glass retort, which will cost only a few shillings at any philosophical instrument maker's, will do to begin with. With stand, receiver, and spirit-lamp, the whole affair need not cost more than 10s. Rain-water should be used in preference to any other, and when the leaves have distilled nearly to dryness, the distillate should be returned to the retort, the old leaves having been thrown away, and new ones substituted. Half a pound of Rose leaves to a pint-and-a-half of water makes a very good change. Our English Roses yield so little perfume that the distillate will have to be re-distilled from fresh petals several times over before a good result is obtained. The neck of the retort must, of course, be kept cool during the operation by having a thick layer or two wrapped round it, upon which cold water is allowed to trickle slowly from a tap or pipe. The receiver, into which the distilled water falls, must be kept cool in a similar manner. To extract the perfume of Violets, Cassia, Jonquil, and Orange flowers, the process of maceration may be adopted. Pure Olive oil or chemically purified lard is melted in a vessel provided with a tightly fitting cover over a water-bath, only a slight amount of heat being employed. The petals of the flowers must be allowed to digest in the warm grease for several hours, care being taken to stir frequently. The grease is then strained through a flannel bag, and the operation renewed until it has been sufficiently impregnated with the odour desired. The perfume may now be extracted by digesting the oil or grease in alcohol in the cold, or it may be used as the foundation of pomades. This process may also be applied to Roses. The still-room was a great institution in old English houses, and ought to be again. Its memory is still kept up in the expression "still-room maid." The grease process would undoubtedly be the easiest to try, for the warmth of an ordinary stove is quite sufficient for the purpose. S. M. N.

THE BEST VIOLAS AND PANSIES.

IN referring to Violas, whether they be old or new varieties, it is sufficient for us, says the "Gardener," that they are the best in richness of colours, quantity, quality, duration of bloom, and good habit. *Viola Alpha* is quite a gem for edging; nothing can surpass it in its dense uniform masses of bluish-purple flowers. *V. Sensation* makes a perfect mass; its flowers are glowing purple: all summer this variety kept its pre-eminence in the flower garden, but *V. Golden Perpetual* came to the front in the autumn to fight the young frosts when *Sensation* lost its gloss. *V. Snowflake* must be received favourably; its profuse supply of large creamy-white blossoms and dense habit are good commendations. *V. Imperial Blue* will be wanted much when better known; its chief attractions lie in its delightful mauve-blue flowers, which are produced profusely, and its clear yellow eye. *V. Admiration* is one of those that lasts out well, having afforded stray blossoms all the winter, showing its hardy nature, and it continues to bloom when the others are over; it is deep violet-blue, showing rays of purple in the eye. *V. lutea grandiflora* is only superior to *lutea major* because of its larger flowers; but, owing to their size, they are not produced in such numbers. Speaking about whites, these are more scarce in variety than yellows or blues. *White Perfection* promises to do well. The worst feature in this division is their tendency to show a blue tint or incline to cream. In bedding Pansies, we are most powerful in the blue section; and a very meritorious and varied assortment may be selected from their number. Perhaps the best of them all is *Waverley*, a kind in the style of *Imperial Blue*; but *Waverley* is likely to supersede it. In colour it is more vivid, in substance and other desirable properties it is quite its equal; but as a perpetual flowerer, taken either in numbers or dense vigorous growth, *Waverley* is far superior to *Imperial Blue*. *Tory* is a very handsome flower and profuse bloomer, but it is deficient in habit, which is thin and

weak compared with *Waverley*; but *Tory* is still one of the best. *White Queen* we consider very superior, having the same qualities to recommend it as a bedder as *Blue King*, from which it is a seedling; but white flowers that come from blue parentage will at certain seasons show a tinge of blue. *White Perfection* is also a good profuse flowering sort, stands out well, and its flowers are neat and full. In yellows, *Buttercup* makes an effective ribbon; its rich blotch of rose-crimson enhances its appearance. *Golden Bedder* may also be grown in quantity; it is very hardy, defying rain and sun alike.

The Age of Standard Roses on the Briar.—It having been stated in discussions as to the merits of the various Rose stocks that Standards on the Briar did not last so long as others do, it is only fair to point out the great age which many Standards have attained. I know a *Jules Margottin* that has stood in moist soil on a lawn for twenty years, and is now a huge specimen with a healthy head. I fancy there are many instances of much older trees than this. Sometimes when the Standards are not too tall, these old and vigorous specimens form picturesque effects, quite different from the "sticky" things Standard Roses usually are.—W. T.

Origin of our Best Herbaceous Phloxes.—The two species from which our best Phloxes have been derived are *P. decussata* (which has given race to the most compact-habited plants) and *P. suffruticosa*, from which northern growers have raised the tall large-blossomed which are now so effective in our borders. All the varieties belonging to these two species grow freely in almost any deep rich soil, and what is of great importance in the case of outdoor plants, rain has but little effect on their flowers except it be to make them look even fresher and more beautiful than they otherwise would. Their colours are strikingly pretty, and the flowers being very persistent are useful in a cut state.—B.

The New Violet Prince Consort.—I am indebted to Mr. Lee, of Clevedon, for this new Violet. It seems after a journey to be larger and lighter and about as sweet as *Victoria Regina*, and Mr. Lee, whose success in the raising of superior Violets entitles him to confidence, considers it superior to any that he has yet raised; so useful and valuable is it to him for bouquet making that he has decided to hold the whole stock until the "orders" for it reach £1000. I hope that a good demand may arise for it, so that those who have ordered it may not have to wait long for their plants. It is also to be hoped that some one will undertake to mount our double Violets on longer legs, so as to make them fit companions for our *Czars*, *Victoria Reginas*, and *Prince Consorts*. The length of stalks becomes an unfortunate matter in the use of Violets for bouquet and wreath-making.—D. T. FISHER.

Cottage Flowers.—I have recently received from the north two pretty single Primroses, one from Northumberland, found growing in an out-of-the-way cottage garden, a pleasing pale lilac kind that has a remarkably dwarf tufty habit, which blooms most profusely; the other, the beautiful variegated hybrid Primrose, from Mr. Clapham, of Scarborough, figured some time ago in THE GARDEN, under the name of *Vesuvius*. This was originally discovered in a farm-house garden, where it was raised from seed. It has long narrow foliage and throws up its earlier flowers on single stems, but later in the season sends up scapes of flowers perfect in form and colour, the latter being rosy purple with a wedge of white at the segment of each petal. It partially belongs to the fancy *Polyanthus* group. Its name is hardly suitable, especially as there is another *Vesuvius* in the field.—A. D.

Tropæolum polyphyllum and its Culture.—*Tropæolums* are not sufficiently appreciated by cultivators, though some of the dwarf, compact-growing annual forms of *T. majus* are often used for bedding purposes. *T. Lobbianum*, it is true, with some of the forms which have been bred from it, is occasionally seen illuminating the roof and pillars of a cool conservatory and the formal beds of the summer parterre, but how seldom we now see specimens of the exquisitely elegant greenhouse pot climbers, *T. tricolorum*, *T. brachyceras*, or *T. azureum*, and in how few gardens are the brilliant hardy *T. speciosum* and the very interesting *T. polyphyllum*! Mr. Wheeler, of Warminster, writes to the "Florist" thus concerning the last-named kind:—"Tropæolum polyphyllum is a hardy tuberous-rooted plant from the mountains of Chili. Being impatient of confinement, it seldom thrives under pot culture, and the most suitable place for it is the open border or the rockery, with plenty of soil for the rambling tubers. Most common garden soil suits it. When a bed of this plant is well established, the ground is covered with a mass of foliage, and it makes a grand display in June; after blooming for a month or so, the foliage disappears for the season, and the ground may be occupied with summer plants without detriment to the *Tropæolum* tubers,

which will send up their flowering stems again in the spring. It does not climb like the other tuberous species, being decidedly decumbent, lying flat on the ground and throwing its pretty glaucous foliage and golden-yellow flowers upwards. In deep porous soil the tubers descend from 2 ft. to 3 ft. below the surface, out of reach of frost, which may damage them if close to the surface, but at 6 in. below they may be considered safe. If permitted to take its natural course, it will take care of itself."

Shelter for Delicate Primroses.—Some Primulas, such as *P. denticulata*, *purpurea*, *pulcherrima*, *nivalis*, and others in the open border, often suffer much from being subjected to heavy showers and frost, a circumstance which induced me to try an experiment which appears to have been successful in its results. Two slabs of sandstone, placed so that they may rest on each other, make a comfortable cover sheltered from the south-east and west, open to the north, but sheltered by a plantation of Fir trees—thus situated, *Primula denticulata* has bloomed well through trying weather, and several other species are coming on well; of course the shade retards the time of blooming, which is perhaps an advantage, as it gives a better chance of good weather.—GEORGE F. WILSON, *Heatherbank, Weybridge.*

A Bright Spring Border.—Spring gardening embraces so many plants that in any place where it is carried out in its entirety it may begin with the Squills, Snowdrops, and Hepaticas, and end with Silenes, Pansies, and Daisies, but in mid-spring, that is, during the month of April, it is possible to find plants that will produce some most effective combinations. One specially bright arrangement produced by plants that are hardy and easily propagated is as follows:—Front row, good patches of the old *Aubrietia purpurea*; next, strong plants of bright red single Primrose; then yellow Tom Thumb and Pansy Yellow Boy supported by the early blue *Myosotis dissitiflora*; the whole backed by a broad line of *Arabis alabica* and a row of the early blood-red Wallflower. The Wallflowers and Forget-me-nots must be raised from seed, the former sown in March and the latter in July. All the rest are easily propagated by means of cuttings and division of the roots.—A. D.

Slugs in the Flower Garden.—Slugs have this year been unusually troublesome in open borders, rock-work and root-work suffering alike, and unfortunately they have made a raid upon the best plants, such as *Colechicum vernum*, *Primula denticulata*, *Omphalodes Lucillia* (of these the leaves were eaten down as fast as they appeared), and Hepatica flowers, especially those of *H. argulosa*. If a few Cabbage leaves be placed the day previous round the plants to attract the enemy, a lodgment will soon be made on them; they can be looked over in the morning and disposed of, thereby saving the blossoms of our favourites from injury. I have recently used collars of perforated zinc, recommended to me some years ago by a clergyman at Ryde, Isle of Wight. For a single Hepatica a strip 1½ ft. long 6 in. deep will suffice, joining the ends with galvanised iron wire; to enclose small Lily beds, use strips about 6 ft. long, joined with wire as required; Cabbage leaves must also be laid round in order to trap any stray slugs within the enclosure. A fine Hepatica *angulosa* in a border unprotected from slugs, had every flower devoured before it had fully bloomed. A great Lily grower in my neighbourhood tells me that Barley chaff will keep off slugs, even after it is quite wet. Mr. Salter uses old greased boards in place of Cabbage leaves to attract slugs.—G. F. W.

Properties of Show Pansies.—The following are those printed for the guidance of the Scottish Pansy Society: FORM.—The outline should be a perfect circle, and free from every notch, serrature, or unevenness, the petals lying close and evenly on each other. TEXTURE.—The petals should be thick, and of a rich glossy velvety appearance. COLOUR.—In all two-coloured flowers, the ground colour (of whatever shade) should be perfectly alike in all the three lower petals, and should be circular, and of equal width between the blotch and the belt in the three lower petals. BELTING.—The belt or margin should be exactly the same shade as the two top petals, and whether broad or narrow, should be of equal breadth throughout, without running into or flushing with the ground colour. BLOTCH.—The blotch should be dense and solid, and of circular character, free from all running into or through the ground colour, or the eye. EYES.—This should be bright gold or orange, and solid, without mixing or running into the blotch, and should be exactly in the centre of the bloom. SIZE.—The larger bloom (other properties being equal) should be the better, but no flower should be considered fit for competition under 1½ in. diameter. SEEDS, of whatever colour, should be of the same shade throughout; if any shading in dark self, it should be soft and delicate; in light self, whether yellow or white, or any intermediate shade, the larger and denser the blotch (other properties being equal) the better.—At a meeting of members of this Pansy Society, held on 27th May, 1871, blooms of fancy Pansies were submitted, and after a full discussion it

was unanimously agreed to fix the following properties as a standard by which to judge them:—First, form; second, texture; third, contrast of colour; fourth, smoothness; fifth, size. Any bloom under 1½ in. in diameter to be disqualified.

The Pasque-flower (*Anemone pulsatilla*).—A large bed of this early-blooming plant is now strikingly attractive in the Wellington Road Nurseries. Of its forms, which are various, we have now before us lilac-purple, reddish-purple, and bluish-purple, all of which vary more or less in the breadth of their floral segments. There are likewise white, dark velvety purple, and double-flowered varieties. The Pasque-flower is a somewhat rare British plant, but on the mountains of France and Austria it may be seen in profusion. The lovely little blue-flowered *Anemone appennina* is also showing colour, and only wants the warmth of a few sunny days to enable it to open its delicate flowers.—B.

Early-flowering Hardy Plants in the North.—Although the weather since the beginning of March has been severe, Snowdrops and Crocuses, now nearly over, have flowered beautifully. *Saponaria calabrica*, sown in pots about the end of August, and transferred to the flower-garden in October, begins to open its blossoms early in spring, and continues in bloom for a long time, as does also the White Arabis. *Pulmonaria angustifolia* is another early flowering plant, and everybody is acquainted with the strikingly pretty blossoms of *Aubrietia deltoidea*, which is the best of the *Aubrietias*. A. *purpurea* does not bloom quite so early, nor does it continue so long in flower; but, nevertheless, it is very beautiful in April and May. *Anemone fulgens* is an early spring gem, requiring a warm situation, in which it need not be disturbed. Its brightness quite equals that of a scarlet Geranium. Then we have in April *Anemone alpina*, *Erica herbacea*, *Polyanthuses* of various colours, Double Daisies, Iberises of several sorts, and Narcissi. Violas, Pansies, and early Tulips also assist to make flower-beds gay until the month of May.—HENRY TAYLOR, *Fencote, Bedale.*

Against Standard Roses.—We are pleased to note that even some of the Rose-growers who grow mainly for exhibition are getting tired of standards. Thus, the Rev. J. B. Camm gives the following reasons for not employing them in the "Journal of Horticulture":—1. They are expensive—First, to buy them you must give fifty per cent. at least more than for dwarfs; secondly, they require stakes and tar twine, and they demand much more labour and time than dwarfs. If you bud them you have to wait half or a quarter of the time that dwarfs do. 2. They do not live half or a quarter of the time that dwarfs do. Their existence is artificial, and they have constantly to wage warfare with their adopted parent. The stock shows fight in every possible way. It throws out suckers from its roots and offshoots for "robbers," as my children call them! all down their stems. They give the buds no peace during their childhood, and then when old enough to take care of themselves, the unnatural parents die. 3. They are more subject to attacks from insects than dwarfs. The Rose grub hides itself in the stock just where the knife mark is, and comes out with the spring to leave a little greasy grub in the young leaf, which, if not discovered, ruins the bud. 4. They are ugly, ungraceful, like mopsticks, and, when not in flower or foliage, are unsightly on the lawn. 5. The stocks are most difficult to procure. I had to make presents to the farmers whose hedges were ravaged by my Briar-men, and had to fit out the latter with new clothes when they had done; for, as they pathetically said, "they were scarcely decent, and really the police be that sharp," &c. Then, too, the stakes are of great moment, even if you live, like I do, in a "woody country."

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Dahlia Maximiliana.—This is a new species from Mexico, with Peach-blossom-coloured flowers; seeds of it are now being offered by American seedsmen. It may be the parent of a new race.

Californian Dog's-tooth Violets.—I am pleased to say my plants of *Erythronium giganteum* are about to flower vigorously in the open ground in sandy soil in a fully exposed position. I, however, have always failed with the Yellow *Erythronium*, so common in the Atlantic States.—T. H.

Violet Culture.—This spring we have had Violets in abundance. We take off the runners and strike them under hand-lights. When struck, we plant them on a north border, using road-scrappings and leaf-soil, in which they make fine large plants by October. They can then be removed to a cold pit, in which ashes are sprinkled between them to protect them from slugs.—R. GILBERT, *Burghley.*

Bulbocodium vernum.—This looks well associated with the *Scilla sibirica* or on bare slopes in the wild garden. It grows about 6 in. in height, and has lovely bright purple flowers, the tints of which vary in different plants. Two or three flowers generally spring out of the same bud and appear before the leaves are fully developed. Several bulbs of it planted together will produce a fine effect, particularly as they are often in bloom as early as February.—Ox.

PLATE XV.

BOXALL'S INDIAN DENDROBE.

(DENDROBIUM BOXALLI).

By F. W. BUREIDGE.

The genus *Dendrobium* is one of the most beautiful and the richest in species in the group of Orchids to which it belongs, the most attractive of which are distributed throughout the different Presidencies of the Indian Empire, and especially in Mouleim, Assam, and Burmah; while others are found in Ceylon and Manilla. As a rule, the Indian species are epiphytal, in their native habitats growing upon trees, both living and dead, and both in sun and shade, the result being that those grown in the sun make shorter and plumper pseudo-bulbs than those which exist in more moist and shady positions, and, as a rule, the flowers, if not so large, are more brilliant. The colour of many Orchids is in inverse proportion to the intensity of the light to which they are subjected. All who have seen *Dendrobies* flowering in India remark that while we obtain stronger growth and a larger quantity of flowers on many of our home-grown plants, yet that these flowers are pallid compared with those borne by native plants, which, in many cases, are literally scorched and withered up, during the dry season, by the Indian sun. In addition to species found in India and the adjacent islands, however, a very distinct group of Orchids is found in Australia; of these the "Rock Lily" (*D. speciosum*) is the best known example, and the beautiful *D. bigibbum*, with its rosy-purple Phalaenopsis-like flowers, the most rare. Two or three other species are also found in China and Japan; but, as has been previously stated, the most beautiful of the whole group are Indian, and consequently require a warm and humid atmosphere (that of an ordinary well-managed plant stove), when making their growth, with copious supplies of water at the same time, and a dry, airy, and sunny position in a vinery or Pine-pit when at rest. Some of the finest specimens of *D. Wardianum*, *D. Devonianum*, *D. crassinode*, and *D. Bensoniæ*, perhaps ever seen were grown on in a warm humid plant-stove, to which air was cautiously admitted during mild nights as well as during the day time; when their growth had attained full size they were removed to a warm and sunny vinery to ripen, and this is the best system to adopt, *i.e.*, provided a regularly-appointed East Indian Orchid-house is not at command for the culture of these and similar-habited plants. As a rule, *Dendrobies* may be readily propagated either by layering the old pseudo-bulbs or by cutting them into lengths and inserting them as cuttings or by dividing strong plants or taking off the side-growths which appear pretty freely on the half-ripened pseudo-bulbs of the previous year. In growing these plants over-potting must be carefully guarded against, for if the roots be embedded in a mass of sour compost they speedily rot, and the energies of the plants are then diverted to the formation of new roots instead of to growth and bloom. Many of the species grow best in small pans, or hanging baskets suspended near the light, and the pendulous-habited kinds look more at home thus managed than when potted and staked in an upright and unnatural position. A compost consisting of fresh fibrous peat, living Sphagnum Moss, and well-dried horse manure suits most of the varieties, coarse, well-washed river-sand being added to keep the whole porous; and a well-drained bottom is highly essential, for although these plants will luxuriate if deluged with tepid water two or three times a day during the hottest summer weather, yet the slightest stagnation or sourness is detrimental to their welfare. The secret of success, indeed, in growing all epiphytes consists in using small pots or baskets of fresh open compost, made firm, so that it does not shift about every time the plant is dipped or watered, and then giving copious supplies of tepid water at the root. It is impossible to over-water plants thus circumstanced, inasmuch as the small well-drained body of compost only holds moisture sufficient to keep the plants in health, and all that is superfluous passes freely away. The culture of many of the most beautiful of all *Dendrobies* need not by any means be confined to the East Indian Orchid-house, properly so called; indeed, a few well-grown plants of *D. Wardianum*, *D. crassinode*, and *D. Devonianum* look far

more beautiful when associated with Palms, fresh green Fern fronds, and other fresh-foliaged plants, than when crowded together among other Orchids, scarcely any of which are interesting to an ordinary observer, except when they are laden with flowers. The following are a few of the best species belonging to this genus; all of them are more or less related to the subject of our plate, the blossoms being borne in few flowered fascicles from the nodes of the long erect or pendulous pseudo-bulbs:—

I.—*D. Wardianum* Section.

Pseudo-bulbs drooping or pendent (except *D. Bensoniæ*); flowers in pairs or threes at the swollen nodes of two-year-old pseudo-bulbs; sepals and petals white tipped with rosy-magenta or lilac; lips yellow, often with crimson blotches.

D. Wardianum (Mr. Ward's Dendrobe).—This is one of the most beautiful of all *Dendrobies* at present in cultivation; it was introduced from Assam nearly twenty years ago, and first flowered in this country in 1858. For a considerable time it was as rare as it is beautiful, but recent importations of it having been made by Messrs. Low, of Clapton, it is now so plentiful that there are but few collections in which it does not occupy a conspicuous position. It varies much in habit of growth, and in the size and colour of the flowers, but all its variations are beautiful and well worth culture. The first plants imported from Assam had a weak pendulous habit, the bulbs, under good cultivation, frequently attaining a length of from 2 to 4 ft. Later Indian importations are, however, of a different type, the pseudo-bulbs being erect or sub-erect, as thick as the thumb, and quite as distinct from the older form as *D. nobile* differs from *D. litiflorum*. There can be no doubt, however, that both types are distinct, although they may appear in habit to belong to different species, and when we come to the flowers we find no distinct and characteristic difference. The sepals and petals are about 2 in. in length, pure white in colour, and of a thick wax-like appearance, their apices being tipped with rich magenta-purple. The lip is rounded and has a circular disc of golden-yellow on which are two large crimson blotches, one on either side the throat, and the apex of the lip is also tipped with lilac-purple. It is difficult to imagine a more beautiful object than this plant when in bloom, bearing, as it does, from twenty to thirty large waxy flowers towards the apex of its thick-jointed pseudo-bulbs. This plant is found to succeed best in a pan or hanging-basket suspended near the light, and during its growth should receive a copious supply of moisture, not only at the root but also in the atmosphere, and, what is of almost equal importance, air should be freely admitted during the night as well as in the day-time, for, although the plant luxuriates in a temperature of from 85° to 95° when growing, it soon languishes unless the atmosphere of the house in which it is growing be fresh and airy. This species is nearly related to the thick-jointed *Dendrobe* (*D. crassinode*), the main points of distinction being the larger flowers and spots on the lip, which are absent in the last-named plant. The beautiful variety which we now figure under the name of *D. Boxalli* seems to us exactly intermediate between the two species just alluded to; and along with them must be classed *D. gratiosissimum*, *D. crystallinum*, and *D. Bullerianum*, all of similar habit, and bearing flowers similar in shape and colour. *D. Falconeri*, which was at one time thought to be the type of *D. Wardianum*, appears to be a distinct and good species; at any rate, it is the most distinct of all the groups just named. A good coloured figure of this plant will be found in Warner's "Select Orchids," t. 19, and in the "Botanical Magazine," t. 5058, where it is described as a variety of *D. Wardianum*.

D. Boxalli (Boxall's Indian Dendrobe).—This distinct and beautiful new *Dendrobe* has been recently imported by Mr. Low, of the Clapton Nursery, where we had an opportunity of sketching it soon after its first flowers expanded. There are one or two distinct forms of it, but all are beautiful, and its free-blooming habit and vigorous growth render it a most desirable plant in a collection. Its pseudo-bulbs are generally pendulous, and in general appearance are exactly intermediate between those of *D. Wardianum* and those of *D. crassinode*. The flowers are also intermediate, being shorter and rather smaller than those of *D. Wardianum*, while the characteristic blotches on the yellow disc of the lip show its affinity with that species.

D. crassinode (Swollen-jointed Dendrobe).—This is a distinct and free-blooming species from Mouleim, from whence both Parish and Benson introduced plants to Kew and elsewhere about 1868. Its knotted-looking pseudo-bulbs vary from 1 ft. to 1½ ft. in length, the flowers being borne in clusters of two or three together at the nodes. When well grown, the last year's bulbs become literally wreaths of white-yellow, blotched, rosy-tipped flowers. It does best in a basket suspended near the light, and requires a copious supply of water when

DENDROBIUM BOXALLI.

making its growth. Of this plant there are several forms, which vary in the size and colour of their flowers. One richly-lined form of it, imported by Messrs. Low, and since called *D. crassinole* var. *Barbieri*, is by far the finest we have yet seen; its vivid colouring, indeed, surpasses that of all other species in this group, *D. Wardianum* not even excepted. We recently saw a vigorous plant of this richly-coloured variety in Mr. Heriot's collection at Cholmeley Park.

D. Bullerianum (Wentworth Buller's *Dendrobie*).—This is a beautiful free-flowering somewhat rare species from Moulmein, whence it was introduced by Messrs. Low. Its pseudo-bulbs are erect, or sometimes slightly pendulous, 1 ft. to 2 ft. in length, and the flowers are borne in pairs from the upper nodes or joints of the two-year-old stems. Each individual flower measures from 2 in. to 3 in. across, and the sepals and petals are of ivory-like whiteness, tipped at their points with magenta or bright rosy-lilac. The rounded lip has a large yellow disc streaked with orange at the base. There are one or two other plants closely resembling this in cultivation, and of these *D. crystallinum* and *D. gratiosissimum* are the best. Like most of the other species in this section, this species grows best in a humid temperature of from 80° to 90°, after which the growth may be ripened by hanging the plants in the dry atmosphere of a sunny vinery, and thus treated the plants flower much more freely than if grown in a hot temperature all the year round.

D. Falconeri (Falconer's *Branching Dendrobie*).—Of all *Dendrobies* this is the most distinct in habit. Its thin pseudo-bulbs being much branched have, when young, a slender and graceful appearance, characteristic only of this species. It grows freely in a warm, humid atmosphere, and seems to succeed equally well in a hanging basket as on a block. The only drawback belonging to the more general culture and appreciation of this plant is that it is somewhat difficult to flower, but this is, doubtless, simply owing to our not having, as yet, learned the proper way to treat it; when it does bloom well it is one of the most gorgeous of all *Dendrobies*, its flowers often measuring 3 in. in diameter, the white sepals and petals being tipped with brilliant lilac-purple, and the lip has vivid crimson blotches on its golden disc, the apex being white and also pointed with lilac-purple. I have seen this plant well flowered by growing it freely in a warm, humid Pine-pit, and, after its growth had nearly fully developed itself, by placing it in a sunny vinery in which the temperature was not lower than that of the Pine-pit where it had made its growth; but, in the vinery, it had the advantage of a more sunny position and drier atmosphere, so that its knotted bulbs became thoroughly ripened and all the thickest nodes showed a pair of fine richly-coloured blooms. No plant requires more moisture at the root when making its growth than this, unless, indeed, we include aquatic; and copious syringings with tepid water at that time are beneficial. It deserves a place in every collection, and no pains should be spared by growers to discover a method of causing it to bloom regularly. An excellent coloured figure of it is given in the "Botanical Magazine."

D. Devonianum (Duke of Devonshire's *Dendrobie*).—This is one of the most delicately beautiful of all the *Dendrobies*, having white magenta-tipped sepals and petals, of membranous or semi-transparent texture, the rounded lips being most elegantly fringed. Well-grown plants of this species often have flower-laden pseudo-bulbs a yard or more in length, forming charming natural wreaths deliciously scented, the flowers themselves being borne in fascicles two or three together at the nodes. This is naturally a pendent habit species, and is well suited for basket culture, suspended near the light when growing; a moist and partially-shaded atmosphere, with a copious supply of water at the root, suits it best.

D. Bensoniæ (Mrs. Benson's *Dendrobie*).—This distinct and attractive species was found in the Rangoon territory, whence it was sent to England about the year 1866 by Lieutenant-Colonel Benson. It is erect, the pseudo-bulbs being from 1 ft. to 2 ft. in height, and covered with membranous sheaths of a bright silvery colour. The flowers measure from 2 in. to 3 in. across, and are produced on the old or two-year-old leafless bulbs, in clusters of two or three at each joint. The sepals and petals are of pearly whiteness, the lip being rounded with a bold disc of clear yellow and two conspicuous black or dark purple blotches towards the base. The contrast between these blotches on a yellow ground and the white petals is of a very striking description, and quite characteristic of the species. The flowers last a month or even longer in beauty, and well-grown plants bloom very freely. It merits a place in every garden where tropical stove plants are grown. As plants of it can be bought by auction as imported for a shilling or two each, this may be grown in quantity, and large baskets or pans of it in bloom are very effective indeed. Good figures of it may be seen in Paxton's "Magazine of Botany" vol. vii., p. 169; "Botanical Magazine," t. 4160; and in the "Flore des Serres," 7, t. 647.

II.—The *D. nobile* Section.

Pseudo-bulbs erect; flowers in pairs or threes at the nodes of two-year-old pseudo-bulbs; flowers white, tipped with rose or lilac; lip white often blotched with crimson.

D. nobile (Chinese *Dendrobie*).—This is so well known as to need little or no description. It is one of the most profuse bloomers in the whole genus, and is grown in nearly every place where cut flowers are in demand. It succeeds either in a pot or in a basket in any fresh open compost, but we have found fresh Sphagnum, peat, and dried horse-droppings to produce the best results. When making its annual growth a high moist atmosphere is essential—that which is afforded by a succession Pine-pit or a vinery in which forcing is going on, with a little care in forcing and retarding the growth of different plants of it a supply of cut flowers, may be obtained for six or eight months of the year; its usual season of blooming, too, being in winter and spring, renders it all the more valuable. Like many of its allies, this species is a very variable one, more especially in the colour of its flowers, some of which are of the richest crimson-purple, almost as brilliant as stained glass, while many of the forms are pale rose. This plant seeds freely, and it would be worth while to sow seeds from the pale forms of it in hopes of obtaining a variety with pure white flowers, or at least with white sepals and petals. The finest examples of this fine old plant I have ever seen are at Chatsworth, some of which measure fully 4 ft. high and nearly 5 ft. in diameter at the base. When well grown this *Dendrobie* deserves a place in every collection of early-blooming stove plants for exhibition purposes. Good coloured figures of it may be seen in Lindley's "Sertum Orchidacearum," t. 3, and in Paxton's "Magazine of Botany," t. 7.

D. Linavianum (Kœmpfer's Japanese *Dendrobie*).—This free-flowering plant was introduced to our collections in 1824, but it was known and figured by Kœmpfer in 1712. That authority remarks that in Japan, its native country, it is common on the walls and hedges. Its flowers and habit of growth closely resemble those of *D. nobile*, but the pseudo-bulbs are more erect, of a paler green colour, distinctly flattened, and the fluting on the nodes is more conspicuous than in that species, added to which characteristics the flowers are of a purer pink colour, and not so purple as in *D. nobile*, nor are the dark blotches of the lip so distinctly marked. Mr. Dominy raised seedlings of this plant some years ago crossed with *D. nobile*, but they resembled the seed parent very closely, and were, I believe, never distributed; Messrs. Veitch, however, still possess these seedlings, and they are interesting as the first seedling *Dendrobies* ever raised in this country or, in fact, in Europe. The plant is of the easiest culture, indeed, it is often grown by florists in a warm greenhouse or pit along with its ally, *D. nobile*, mainly for its supplies of cut flowers during winter and spring. A few plants of it should be grown in every plant stove or warm vinery wherever cut flowers are in demand. It grows best in a pot of peat and Sphagnum, and requires a copious supply of tepid water when growing; like *D. nobile*, an occasional dose of weak manure-water assists it immensely in forming tall plump pseudo-bulbs. There are two or three distinct varieties of this plant, *D. Linavianum majus* being the best. It is generally known as *D. moniliforme*, a name which rightly belongs to the small white-flowered *D. japonicum*. Coloured figures of it are given in the "Botanical Magazine," t. 4153, and in the "Botanical Register," t. 1314.

D. transparens (Transparent *Dendrobie*).—This is one of the prettiest little plants belonging to the *D. nobile* group, the main distinction from the last-named species being its extremely slender habit and smaller flowers. It is a native of India, and grows freely in a warm and humid temperature, producing white lilac-purple-tipped flowers abundantly in April or May. It does best in a small pot of fresh fibrous peat and Sphagnum Moss, and must be copiously watered when making its growth, which it does immediately after flowering. It is tolerably plentiful, and deserves to be grown in quantity as its flowers, being small and more elegant in shape than those of *D. nobile*, are better adapted for bouquets or button-hole flowers. I have seen it in charming condition in hanging baskets; its flowers are richer in colour thus grown close under the glass than when in a pot on stages farther from the light. Good coloured illustrations of this plant may be found in the "Botanical Magazine," t. 4663, and in Paxton's "Flower Garden," t. 27.

D. amœnum (Sweet-scented *Dendrobie*).—In general habit this closely resembles the last-named plant, but the magenta tips of the ivory white flowers are brighter, and the flowers are deliciously scented, even more so than in the case of *D. heterocarpum*. It was imported by Mr. W. Bull in 1875, and was much admired when shown at the spring exhibitions of the Royal Botanic Society. It grows freely in a pot, treated in the same way as *D. nobile*, but it requires a little

more heat than that kind. Like *D. transparens*, its flowers are elegant in outline and well suited for cutting and arranging in bouquets, where their distinct and delicate perfume is always welcome. It deserves a place in every collection, however small. A good figure of it is given in the "Botanical Magazine."

D. tortile (Twisted Dendrobe).—This is a native of Java, and, in order to be successfully grown, it requires a high temperature. Its pseudo-bulbs are smooth, thickened at the nodes, and from 1 ft. to 1½ ft. in length, the flowers being produced in twos and threes from the thickened or swollen nodes. The sepals and petals are whitish and twisted something like those of *Trichopilia tortilis*, and the rounded lip is of a pale primrose colour. One variety, *D. tortile roseum*, has the segments suffused with rosy lilac, and is a much more showy and attractive plant of the species. It succeeds best grown in a hanging basket, in peat and Moss, and suspended near the light. Its flowers are produced in profusion in May or later. They are delicately scented. It is not so common as many other species, but well deserves a place in every collection. A good coloured figure of it is given in the "Botanical Magazine," t. 4477.

D. Parishii (Parish's Dendrobe).—This is a compact-habited species from Moulmein, whence it was sent to our gardens by the Rev. C. Parish about 1862. Its pendent pseudo-bulbs are as thick as the little finger; they are seldom over 1 ft. in length, and are covered with dry silvery membranous sheaths. The flowers are produced in pairs from the nodes of the two-year-old buds, and are of a rich crimson-purple, and measure about 2 in. across. The lip is whitish, with a dark stain on both sides of the throat; it grows well in a basket suspended near the light. Mr. Bateman, in alluding to the advent of this showy little species, says:—"It bears a certain resemblance to *D. noble*, but is in reality perfectly distinct from that species. Even when out of flower, it is readily distinguished by its thick clumsy leafless stems, which are bent downwards in a stiff ungainly manner, while the stems of *D. noble* and *D. moniliforme* hold themselves erect, and taper gracefully towards the base." When growing, it requires plenty of heat and copious supplies of moisture at the root. A good figure of it is given in the "Botanical Magazine," t. 5488.

D. lituiflorum (Trumpet-lipped Dendrobe).—When well grown, this is one of the most attractive of all the pendulous-habited Dendrobes, bearing often from twenty to thirty large rich purple and white flowers, on slender leafless bulbs, a yard or more in length. A plant of this species, shown at South Kensington on March 15 of this year, bore forty-three large and highly-coloured flowers on two pseudo-bulbs, considerably over a yard in length. It came from the collection of Sir H. Peck, at Wimbledon House, and was much admired. It grows best in a basket suspended near the light, and, like all Indian Dendrobes, requires an abundant supply of water when making its growth in June and July. It grows so freely, and is without so extremely beautiful, that no collection of Orchids can be said to be complete without it. Its flowers at first sight remind one of those of a dark variety of *D. noble*, but the lip is longer and whiter, and the sepals and petals are of a richer violet-purple tint, to say nothing of the distinct drooping habit of the plant. Good figures of it are given in the "Botanical Magazine," t. 6050; and in Warner's "Select Orchids," (second series, t. 3).

D. Macarthæ (Mrs. Macarthy's Dendrobe).—This is one of the most beautiful and, at the same time, one of the most rare of all Cingalese Orchids, and it is also totally distinct from any other known species. Its pseudo-bulbs are long, slender, and pendulous, and have swollen dark-coloured joints, the internodes of which are covered with pale membranous sheaths; indeed, in habit this plant and the golden-flowered *D. Hookeri* are nearly identical, although its flowers are distinct. They are produced in fascicles of two or three together, and are about 3 in. in length, of a bright rosy colour, the lip being white with purple markings; the sepals and petals do not expand, as in the case of all the other species, and the bottom of the flower is quite flat. It succeeds best on a block or in a basket, and well-managed specimens of it bear from fifty to one hundred flowers fully expanded at the same time. In its native habitat (Caylon) it is found hanging from the tallest forest trees in the most inaccessible parts of the island, and is known as the "Rainy Month" or "May-flower." It requires a moist warm atmosphere, especially when making its growth, and is so distinct and beautiful that it deserves a place in the most select collection. A coloured figure of it is given in the "Botanical Magazine," t. 4886.

III.—The *D. chrysotis* Section.

Pseudo-bulbs drooping; flowers in few or many-flowered racemes; sepals and petals, yellow; lip, yellow, its margin much fringed.

D. chrysotis (Dr. Hooker's Dendrobe).—This is by far the finest of all the pendent-habited, yellow-blossomed species, and well deserves

attention. A few years ago a plant of it in the Manley Hall collection produced twenty-five spikes, on some of which there were nine flowers, and the individual blooms measured considerably over 3 in. across. The sepals and petals of this species are of good substance, and of a deep golden-yellow colour, the rounded lip being also yellow and finely cut into long eyelash-like fringes, the effect being considerably enhanced by a pair of vivid crimson blotches, one on either side of the disc. This plant was first discovered by Dr. Hooker in Sikkim in 1848, and has been figured in the "Botanical Magazine" as *D. Hookerianum*, a name under which it is sometimes found in gardens and trade collections. In its native habitat it seeds freely and there are two distinct varieties of it in cultivation. It has been erroneously stated to be only a form of the old and well-known *D. fimbriatum oculatum*, from which, however, it is quite distinct. It produces flowers on the slender and pendulous growth of the current year, the nodes being dark and shining, and somewhat thickened or swollen. A plant of it in Mr. Heriot's collection has pseudo-bulbs nearly 5 ft. in length, and has borne flowers in profusion. Its blossoms last six or eight days in beauty. Coloured figures of it are given in the "Florist," 1871, p. 145, and also in the "Botanical Magazine."

D. Cambridgeanum (Dwarf Golden Dendrobe).—This is a showy species from northern India, of dwarf habit, having short thick green pseudo-bulbs, which fall over the edges of the pot or basket like those of *D. Parishii*. It is a plant which grows well enough in a warm humid temperature, but to bloom it well it must have a liberal allowance of sunshine. A block, or a small hanging basket of peat and Sphagnum suits it best, and it requires a copious supply of tepid water at the root, especially when growing. Several specimens of it are now in bloom in Messrs. Veitch's collection at Chelsea. The individual flowers are about 3 in. in diameter, the sepals and petals being of a rich orange or golden yellow colour, the rounded fringed lip bearing a conspicuous crimson blotch on the disc. When well grown this is one of the most effective of all the yellow-flowered Dendrobes belonging to this section, and its dwarf and compact habit is an additional advantage where space is limited. Good coloured illustrations of it are given in Paxton's "Magazine of Botany," vol. vi., t. 265; and also in the "Botanical Magazine," t. 4450.

D. chrysanthum (Crimson-golden Dendrobe).—A well-known Indian species, of robust habit, the pseudo-bulbs of which, in the case of liberally-treated specimens, often measure from 4 to 6 ft. in length, and, when well-ripened, form perfect wreaths of thick, wax-like, golden flowers, which last two or three weeks in perfection. When well-grown few plants are more useful than this Dendrobe for furnishing cut bloom or for conservatory decoration. It likes a rich compost consisting of peat, living Sphagnum, nodules of charcoal, and a few handfuls of dried horse-droppings, all well inter-mixed, and, like *D. noble* and one or two other strong-growing kinds, a little manure-water given twice a week will be found of service to it when in active growth. Its flowers are borne in fascicles of from two to seven at the nodes of the current year's growth. The yellow sepals and petals are short, thick, and rounded, of a glossy character, the lip being rounded, slightly fringed, and of a golden-yellow colour blotched with reddish-crimson. A good coloured figure of it may be seen in the "Botanical Register," t. 1299.

FLORAL DECORATIONS FOR APRIL.

The flowers available through April do not materially differ from those to be had in March; though they may now be obtained in larger quantities and at lower prices, owing to many of them being in bloom in the open air, which previously were under glass. At the same time there are some, which, though in blossom at the beginning of the month, will be all over long before the end of it, if they be not kept back by continued dull weather, and to these a query (?) will be found appended. The list of blue flowers (at all times a short one) is increased by the addition of *Nemophila* (forced), and by *Forget-me-not* and *Venus' Navelwort* from the borders, the latter (*Omphalodes verna*) having the purest blue colour of any flower yet mentioned, while the Siberian Squill presents the darkest shade of pure blue. The two-leaved Squill is a welcome addition to the list of purple flowers, and there are other species of *Scilla* which might here be enumerated, but that they are not commonly grown to such an extent as to be available for cutting. In old gardens may now be found large clumps of the pink Dog's-tooth Violet (*Erythronium*), a lovely little liliaceous plant which does not like its roots disturbed by digging, and which is consequently never seen after the first year, where "jobbing gardeners" are employed. The buds of forced *Roses* appear to me to be of purer and better colours this spring than heretofore in the shops of the London florists, and, considering the unusual backwardness of the season and the

absence of sun-light, it is difficult to account for this, while it is at the same time highly creditable to the growers. Covent Garden Market is indebted to Mr. Bennett, a nurseryman in Wiltshire, for a good supply of buds of two new Roses of small size, with good form and colours. The yellow one (*Perle du Jardin*) to which I refer, is a seedling from *Gloire de Dijon*, and is like a small *Maréchal Niel*, or a partly edition of *Isabella Sprunt*. The other Rose is a rich orange, about half the size of *Madame Falcoi*, but with much richer colour and better form, while, for fragrance, there are very few Roses to match it, the scent resembling a blend of *Violets* and *Apricots*; it is a seedling from *Vicomtesse de Cazes*, and, as a button-hole Rose, stands in my estimation "at the top of the tree." It is called *Madame François Javin*.

Blue—*Cineraria*, *Hepatica* (?) *Hyacinth*, *Myosotis*, *Nemophila*, *Omphalodes*, *Siberian Squill*.

Purple—*Cineraria*, *Crocus*, *Heliotrope*, *Hyacinth*, *Two-leaved Squill*, *Tulip*, *Violets*.

Mauve—*Cineraria*, *Heath*, *Primrose*, *Tulip*.

Pink—*Almond*, *Azalea*, *Begonia*, *Bouvardia*, *Camellia*, *Carnation*, *Chinese Primrose*, *Cyclamen*, *Dielytra*, *Dog's-tooth Violet*, *Fancy Pelargonium*, *Fuchsia*, *Heath*, *Hyacinth*, *Ribes*, *Rose*, *Tulip*, *Zonal Pelargonium*.

Crimson—*Bouvardia*, *Camellia*, *Cyclamen*, *Cydonia* (*Pyrus*) *Japonica*, *Fuchsia*, *Hyacinth*, *Polyanthus*, *Primrose*, *Ribes*, *Rose*.

Scarlet—*Bouvardia*, *Carnation*, *Euphorbia* (?), *Salvia* (?), *Tropæolum*, *Tulip*, *Zonal Pelargonium*. Also berries of *Aucuba*, *Cotoneaster*, and *Solanum*.

Orange—*Carnation*, *Crocus*, *Narcissus*, *Polyanthus*, *Rose*, *Tulip*.

Yellow—*Azalea*, *Coronilla*, *Genista*, *Hyacinth*, *Lachenaia*, *Narcissus*, *Polyanthus*, *Primrose*, *Rose*, *Tulip*.

White—*Andromeda*, *Arum*, *Azalea*, *Begonia*, *Bouvardia*, *Camellia*, *Carnation*, *Chinese Primrose*, *Crocus*, *Cyclamen*, *Eucharis*, *Heath*, *Hyacinth*, *Laurestinus*, *Lilac*, *Lily of the Valley*, *Narcissus*, *Paper Narcissus* (?), *Pink*, *Roman Hyacinth* (?), *Snowy Medlar*, *Spiræa*, *Tulip*.

—W. T. T.

ANTHURIUMS AND THEIR CULTURE.

Of these, four especially deserve a place in even the most select collection of stove plants; but as they require somewhat different treatment as regards soil, it will be necessary to speak of them separately. First, therefore, let us take the white-spathed kind, *A. candidum*, a Columbian plant of somewhat slender habit, with rather small, erect, ovate, lanceolate leaves, on proportionate root-stalks; its spathes are about 3½ in. in length. It associates well with *A. floribundum*, a New Grenada species, with much broader, slightly lanceolate leaves, dark green, and of compact habit; the spathes of this plant are also white; it lasts long in flower. Both may be increased by division of the crowns taken off in the spring when they have made a few roots from the base. That these exist before the crowns are separated from the parent plant is essential, as if taken off before they have formed roots independent of the plant that has produced them, they will be long in growing away freely. When taken off, place them singly in pots no larger than the roots can be got into without injury. They are surface-rooters, requiring an abundance of water; consequently they do not need a great depth of soil, but they must have plenty of drainage material, which should half-fill the pots; the soil should consist of fibrous peat, three parts to one of flaky rotten manure that has been well dried. Mulching that has lain exposed on the surface of a Vine border or an Asparagus bed is the best for Anthuriums: add to these a fifth part of leaf-mould, a good sprinkling of crocks broken the size of Horse Beans, and a fair quantity of silver sand, mixing the whole well together. Do not, even whilst the plants are small, sift the soil, but pull it to pieces with the hand; press moderately firm, and put the crowns an inch or so down, just covering the roots a little; put a small stick to each for support, give water, and place them in a brisk heat of 65° or 70° at night, increasing it during the day. Keep them a little close until they begin to grow, but not so much so as would be requisite in the case of ordinary cuttings. Raise the temperature both day and night as the season advances, giving air in the day time when the weather is such as to require it, and shading slightly when the sun is upon them. When a fair amount of roots has been formed, the plants should be moved into pots 2 in. larger, using similar

soil to that in which they were last placed. Continue to treat them through the summer as already recommended, syringing them freely every afternoon, and also giving plenty of water to the roots. Reduce the temperature and discontinue shading as the weather gets cooler, keeping them through the winter in a temperature of from 55° to 60° at night; but do not let the soil get dry. Re-pot in April, giving 2 or 3 in. of a shift, still half-filling the pots with drainage, and using the soil in a more lumpy state as the plants get larger; this season they will push up flowers from all the strongest leaves; but it will not be advisable, even whilst in bloom, to move them out of the stove, as a lower and drier atmosphere would interfere with their growth. Continue the summer and winter treatment in this and subsequent years, as already recommended, giving more pot room when it is wanted. They will go on for years increasing in size as long as required, and when they get larger than desirable, they may be reduced by division of the crowns. They may be increased by means of pieces of their rhizome-like stems cut into portions 1 or 2 in. in length, inserted in soil such as that recommended for potting the crowns in, and treated similarly afterwards. They may likewise be raised from seeds managed as hereafter recorded, as regards the propagation of *A. Scherzerianum* and its white variety.

A. Scherzerianum, which is now well known, is undoubtedly one of the very finest flowering plants ever introduced to this country. By judicious treatment it has been grown to a size never anticipated when we first became acquainted with it. It is from Costa Rica, and can be readily increased from seeds. For a considerable time after it was brought to this country very succeeded in seeding it simply through not allowing time for the seed to get matured; they are borne on the outside of the spadix in compressed globular, pulpy masses, about the size of, and when ripe the colour of, pale Red Currants. To produce good seed, flowers should be selected that open towards the close of the summer; about August, when the spathes decay they may be cut off, leaving the twisted spadix growing upon the peduncles. These will remain through the winter in much the same condition; in autumn they appear quite brown, with little apparent vitality in them, but in spring the spadix will all, or partially, untwist, and the seed-vessels will begin to swell, keeping at first green, after which they gradually change to an orange-red as they ripen. When fit to gather they are almost transparent, and will part readily from the spadix. They should then be removed, washed out of the pulp in which they are embedded in the way usual with Melon or Cucumber seeds, and ought to be at once sown. Procure large-sized pans, and place in them an inch of drainage; then get some clean Sphagnum Moss, free from Grass or weeds, and cut it quite fine with a pair of scissors or hedge shears; then add to it one-fifth of clean sand and some crocks or charcoal, broken about the size of small Peas; fill up the pans with this mixture, pressing it firmly down, and water the surface, sprinkling a little more sand if that which has been already mixed with the Moss is washed down; damp the surface again, and sow the seeds thickly and evenly over it, pressing them gently down with the hand, but not covering them in any way; put a propagating glass over the whole to keep in the moisture, which will prevent the necessity for giving much water, as, if this be required in considerable quantities, it has a tendency to wash the seeds into the material, which must not occur, as they vegetate best on the surface. Keep the whole quite moist; it must never be allowed to become dry, but, when water is given, let it be applied through a fine rose, so as not to disturb the seeds at all. Place them in a night temperature of 65°, allowing 10° more in the day time; in a few weeks they will begin to grow, and as soon as the young plants are large enough to handle, prick them off into 3 in. pots, half-filled with drainage, in similar material to that in which the seeds were sown; put them an inch apart, and keep the compost well moistened, for the Anthurium is a semi-aquatic, and cannot endure to be dry at the roots. Let the young plants, from the time they first vegetate, have plenty of light, but do not allow the sun when at all powerful to come upon them without shading; give air in the middle of the day, and syringe overhead in the afternoons; when they have made a couple of leaves an inch long, move them singly into thumb

pots, still using the Sphagnum and sand mixture. By the end of August the most vigorous should be moved into pots a size larger, now mixing a little fibrous peat with the Moss, sand, and small crocks. The least plants had better remain undisturbed until the following spring. Keep them through the winter in a night temperature of 55° or 60°, and a few degrees warmer during the day. This is considerably hotter than is requisite for them when they get larger; but the object now is to push them on without loss of time. Place them where they will be fully exposed to light, and damp them overhead every day with the syringe. By the beginning of March all will want moving to larger pots; but do not give too much root-room, or the soil will get sour, in which case the roots are sure to perish. Increase the temperature, give air and shade as the days lengthen, similarly to the preceding season. About the end of June most of the plants will need a size larger pots, adding now a little more peat to the Moss. Any that attempt to bloom this season should have their flowers pinched out as soon as they appear, for, if flowering be allowed to go on, it will seriously retard their growth. Treat them through the autumn and winter as before. Again pot them in the spring, now and subsequently using half good fibrous peat with the Sphagnum, sand, and crocks. This summer they may be allowed to open a few flowers. Most of the blooms will differ more or less in size, shape, and depth of colour, and they should be removed before seeds are formed, as that would stop their progress. Those that have the largest and best formed flowers should be marked, and have especial encouragement. As they grow up into a useful decorative size, they may be kept at 50° at night during the winter season, at which they should not have so much water, but still enough to keep them growing. They will make the strongest leaves in the winter; through the spring and summer let the night temperature be 10° or 15° higher, and proportionately warmer in the day time. They will go on making larger leaves and flowering until they get five or six years old, as well as forming numbers of crowns, increasing the bulk of the plants for an indefinite time, provided the soil is never allowed to become sour and adhesive, in which case the roots are sure to perish. To avoid this, each year when re-potted, get as much of the old exhausted material away as can be done without injuring the roots. The best time to re-pot them is in summer, after the principal blooming is over; this will depend upon the temperature in which they are kept during early spring, as the warmer they are the earlier they throw up the main crop of flowers. The white form of *A. Scherzerianum* requires treating in every way like the red variety. Both can be increased by division of the crowns, and by pieces of the rhizome in the manner described for *A. candidum* and *A. floribundum*.

Thrips and green fly are both partial to the leaves and flowers of Anthuriums, but the continuous syringing recommended is generally sufficient to keep them in check, otherwise they may be killed by fumigation. Brown scale thrives upon the leaves, and must be kept under by sponging, as likewise mealy bug, should they become affected with it. T. BAINES.

Camellias Dropping their Buds.—A correspondent of the "Gardener," says, he has good reason to believe that Camellias drop their buds from being over-excited with heat, or any treatment which tends to produce leaf or foliage growth before the buds are fully and firmly grown—the plant will not at the same time develop its flower-buds and produce its new leaves; ergo, the plant must be kept in the cold, even to the extent of some degrees of frost, before any encouragement should be given to the development of its flowers.

Dwarf Fan Palms for House Decoration.—In THE GARDEN for April 1st, it is stated that gas and violent draughts of cold are destructive to all plants in a dwelling-house. From this rule there is certainly one exception—the different varieties of Chamærops, which we have kept in good health and appearance for years in succession in the worst possible positions, both as regards light, heat, and draughts. Where these will not live and keep in fair health, the growing of plants may be given up, and a stock should be obtained of the cast-iron Aloes which are used to decorate some gardens. It is probable that these, if painted regularly, would not lose their foliage very readily; but the Palms in question are nearly as easy to keep, and want but little more attention. They are perfectly

hardy here, standing outside all winter without any protection; in fact, they have the constitution of the cast-iron works of art before referred to, with the advantage of growing and changing their form every year, which the cast-iron variety of Aloe has not, and they have also the advantage of being less costly. When all other things fail, I should advise a trial of these Palms, and if they do not succeed plant-growing may safely be given up as hopeless.—THOS. FLETCHER, Warrington.

Centranthus Lucianus.—This rare plant is the admiration of all who see it. It is in flower more or less for the greater part of the year, but is in its fullest perfection during the four or five months of winter, when it blooms most abundantly in a hothouse. The flowers are long and numerous, of a rich red, and are disposed in a kind of umbel, last a long time, and succeed each other continuously. MM. Rougier, Chauvière, Thibaut, and Keteleer are the principal cultivators of this beautiful flower, which, although its culture and propagation present no difficulties, is nevertheless rarely met with in hothouses.—"Revue Horticole."

Gesnera Houtteana coccinea.—This plant was raised some years ago in the Wellington Road Nurseries, in which it is now in bloom, and it is certainly one of the most distinct of its class. It has thick woody root-stocks, from which its soft hairy stems rise to a height of 18 in. clothed with velvety cordate leaves, and terminated by axillary clusters of hairy tubular flowers, nearly 3 in. long. These flowers are of the most vivid scarlet colour, imaginable, so brilliant indeed, that by the side of them many other so-called scarlet flowers look, comparatively speaking, brick-red. White fresh green Ferns and white-flowered Gardenias, Deutzias, Hyacinths, and Narcissus, look whiter still by being associated with them. Like others of the section to which it belongs, the plant can be stowed away during the autumn and winter months, and started again early in spring, when its brilliant flowers and velvety leaves are required for decorative purposes.—B.

Citrus trifoliata as a Stock for Oranges.—This spinose species of the Orange family has proved thoroughly hardy in Messrs. Henderson's Nursery at St. John's Wood, planted out in a deep rich border, and trained on a sunny wall. It is the *Limonia trifoliata* of some gardens, and is principally used as a stock on which to graft the more choice and tender varieties of Oranges, and more especially for the delicious little *Citrus japonica*, or Kumquat, which indeed can scarcely be induced to perfect its egg-like fruits in cultivation unless worked on this species. The only place with which we are acquainted where this deliciously-flavoured and ornate little Orange is successfully grown is at Knypersley Hall, Cheshire; but if worked on the above-named stock, there can be no difficulty in growing and fruiting it elsewhere in a warm greenhouse or plant stove.—B.

Floating Island in an Aquarium.—I have the pleasure of giving particulars (says a correspondent of "Science Gossip") of a pretty appendage to the aquarium, namely, a floating flower-garden, which has been in operation about a month. I procured a piece of rough "virgin cork" (such as used for ferneries, rustic work, also by photographers), about 9 in. long by 5 in. broad, the thicker the more buoyant, floated it to observe its position, then, from the highest ground, bored two holes about an inch or so in diameter, and a little distance apart, over which I placed two Hyacinth bulbs; the roots soon reached the water. From the present healthy appearance of the leaves I have every hope of the success of my scheme. The fish appear pleased with the addition, and have availed themselves of the shade offered by the floating garden.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Passiflora princeps.—This, when fully established, is nearly always in flower—not one or two blooms, but long wreaths or racemes sufficient in themselves to brighten up any structure, and when planted out in a well prepared border few slow plants are less liable to insect plagues.—J. GAZON, *Zenith*.

Cytisus alipes for the Greenhouse.—I find this as effective and graceful in my small conservatory as the Weeping Willow is in the open garden, only that my delicate weeping Broom bears many pure white flowers. I got my plants from Messrs. Osborn, of Fulham, who, I believe, graft them on the common Laburnum.—L. L.

Caltha leptosepala.—This pretty plant (says "The Gardener") is suitable for planting in moist positions. It grows somewhat in the style of, and about the same height as, *Ficaria ranunculoides*, but with considerably larger pure white flowers internally, externally shaded with yellow. It is a native of the Rocky Mountains.

The Small Creeping Fig (*Ficus minima*).—This delicate-looking little plant, a miniature of *Ficus repens*, is valuable for covering walls with a smooth coat of green leaves. There is a wall well covered with it in one of the houses in the Royal Exotic Nursery at Chelsea. Its slender habit, as compared with that of the larger kind, makes it valuable as a creeper on the surface of pots, and for tree Ferns and other stems.

TREES AND SHRUBS.

THE DOVASTON YEW.

The following, quoted from Loudon's "Arboretum Britannicum," is the correct history of *Taxus baccata* Dovastonian, or Dovaston Yew. "The Westfelton Yew stands in the grounds of J. T. M. Dovaston, Esq., at Westfelton, near Shrewsbury, and the following account has been sent us by that gentleman:—About sixty years ago (now 100), my father, John Dovaston, a man without education, but of unwearied industry and ingenuity, had with his own hands sunk a well, and constructed and placed a pump in it; and the soil being light and sandy, it continually fell in. He secured it with wooden boards, but perceiving their speedy decay, he planted near to the well a Yew tree, which he bought of a cobbler for 6d., rightly judging that the fibrous matting tendency of the Yew roots would hold up the soil. They did so, and, independently of its utility, the Yew grew into a tree of the most extraordinary and striking beauty, spreading horizontally all round to the diameter of (now 1836) 56 feet, with a single aspiring leader to a great height, each branch in every direction dangling in tressy verdure downwards, the lower ones to the very ground, pendulous and playful as the most graceful Birch or Weeping Willow, and visibly obedient to the feeblest breath of summer air. Its foliage is admirably adapted for retaining the dew-drops; and, in consequence, it makes a splendid appearance at sunrise. Though a male tree, it has one entire branch self-productive, and exuberantly profuse in berries, full, rich, red, and luscious, from which I have raised several plants, in the hope that they may inherit some of the beauty of their parent. The circumference of the tree, now at 5 ft. from the ground, is 5 ft. 1 in.; and it is in a growing state quite healthy and vigorous. I have just been favoured with a letter from the present proprietor of Westfelton, giving the present dimensions of the Dovaston Yew. In 1836 the diameter of its branches was 56 ft., and this year it is 72 ft.; circumference of trunk, at 5 ft. from the ground, in 1836, 5 ft. 1 in.; the same in 1876, 7 ft. 6 in.; present height, 34 ft. One of the pendent branchlets, kindly sent me by Mr. Dovaston, measures 2 ft. 3 in. from its junction with the branch. The accompanying illustration, though it hardly does the tree justice, will give some idea of its beauty. I have a fine golden form of it about 3 ft. high, very graceful. Mr. Dovaston informs me that seedling plants from this tree partake of the same pendent character as that of the parent.

WILLIAM BARRON.

Elvaston Nurseries, Borrowash.

Clematis ligusticifolia.—This is a remarkably strong and vigorous growing hardy Clematis, forming a good companion to the well-known *C. virginiana* of the Eastern States. W. C. American Gardener's Monthly notes that it is now being offered in several seedsmen's catalogues.

HORSE CHESTNUTS.

These form a small but interesting group of deciduous trees, indigenous to many parts of Asia and North America; they are remarkable for their symmetrical habits of growth, handsome foliage, and showy flowers, which, in large specimens, are produced in great abundance. They are perfectly hardy, and grow freely in almost every kind of soil, but they prefer that which is of a deep, rich, loamy character. Since their introduction, the various sorts, and notably the Asiatic form with its varieties, have been largely planted and with good effect in our parks and woodlands. Though in some instances they attain considerable dimensions, the timber is too soft, and easily acted on by the weather, to be available for other than minor or temporary purposes; and they are therefore rarely or at least sparingly introduced by foresters into plantations from which profitable returns are expected. The undomestic species and varieties are very distinct, and deserve the especial attention of planters for ornament.

Æsculus Hippocastanum (Common Horse Chestnut).—This is indigenous to the north of India and to various other of the temperate regions of Asia; it grows to heights of from 50 ft. to 70 ft., and, in exceptionally favourable circumstances, even to 100 ft. It is reported having been in cultivation as an ornamental tree in southern and central Europe for more than 300 years, and the date given for its introduction to Britain is 1629. When planted in a park, and allowed to branch out on every side without interruption, it forms a surpassingly handsome tree, with a broadly pyramidal and regular outline. The branches are long and numerous; the bark of a pale brown colour; and the large, prominent leaf-buds thickly coated with a dark gummy or resinous substance, which becomes glutinous in early spring, and gives the tree an interesting appearance. The leaves are large, palmated, usually with seven leaflets, the two lower ones much smaller than the others; they are of a light

The Dovaston Yew.

green tint when developing in April and May, becoming darker when matured. The flowers, which expand shortly after the leaves, are white, spotted with delicate pink and yellow. They are disposed in large, erect, Hyacinth-like spikes, from the points of the young shoots. The fruit capsules are prickly, and contain from one to three nuts, which are ripe in September or October. They are so bitter as to be useless as food; but it is said that "that quality can be extracted by chemical processes, and then, when the kernel is ground and mixed with wheat-flour for bread, it is agreeable to the taste, and very nutritious." For massive grandeur of form, graceful foliage, and beautiful flowers, the common Horse Chestnut yields to none of its companions in our pleasure-grounds. It forms a noble characteristic object in the landscape at all seasons of the year, and superlatively so in early summer. It is scarcely necessary to say that it is hardy enough to stand the severest winters in any part of this country; and, though of rapid growth in moist soils, comes to the greatest perfection in deep loam, with a dry sub-soil, and in situations sheltered from wind, which injures the young leaves. Of a number of sports and seminal varieties in cultivation, the following are distinct and worthy of introduction into collections of choice trees.—*Æ. H. argentea variegata*—in this form the leaves are more or less blotched with silvery white; *Æ. H. aurea varie-*

gate—blotched with yellow in a similar manner to the preceding. Both these variegations are interesting, and when in character very showy; in some soils, however, they are not very constant, and have a tendency to revert to the original green; *Æ. H. carnea*—the flowers of this variety are pale pink, and very showy; *Æ. H. crispum*—so named from its leaves being curiously crisped, it forms a pretty, distinct-looking specimen tree; *Æ. H. flore-pleno alba*—flowers semi-double, but otherwise identical with the species; *Æ. H. flore-pleno rubra*—another semi-double variety, with pale pink or red flowers; *Æ. H. incisum*—the leaflets of this sort are deeply cut into shred-like divisions. It is an interesting and very elegant tree, well suited for a prominent situation on a large lawn, or for associating with the taller growing shrubs in mixed collections.

Æ. ohioensis (Ohio Horse Chestnut).—As its name implies, this is one of the American forms of the genus. It was first sent to Britain about 1820, and is reported as occurring not only on the banks of the Ohio, where it was first discovered, but more or less abundantly over several of the States, particularly in Western Pennsylvania and Kentucky. In its native habitats it forms a moderate-sized tree, rarely exceeding 20 ft. in height, and in high exposed situations dwindling down to a bush of about 8 or 10 ft. The leaves are pale green, divided into five leaflets, much smaller than those of the typical species. The flowers, which expand in May, are creamy-white tinted with pink, and are borne in erect spikes from the points of the young shoots. The nuts are enclosed in small prickly capsules, and are usually ripe in October. Though not often met with in our pleasure grounds, this is a beautiful ornamental tree, resembling in general appearance the common Horse Chestnut, but sufficiently distinct to render it very desirable for planting in parks, avenues, or spacious lawns. It requires a deep, rich, and well-drained soil, and succeeds best in situations sheltered from the blast.

Æ. rubicunda (Red-flowered Horse Chestnut).—This species—or variety, for a great diversity of opinion prevails among botanical writers as to its claims to rank as a species, some regarding it as a hybrid or sport from *Hippocastanum*—is recorded as having been introduced from North America in 1820. In general appearance it resembles the common Horse Chestnut, but is less robust in habit of growth, and rarely exceeds 30 ft. in height. The leaves are similar to those of that species; and the flowers, which even on comparatively young specimens are produced in great profusion, differ only in being of a deep pink or rose colour. It is, moreover, easily distinguished in winter by its lighter-coloured bark, and the almost entire absence of that gummy secretion which forms such a prominent feature on the buds of the common sort. It succeeds perfectly under the same conditions which are necessary for the well-being of its congeners, and is, beyond question, one of the grandest of our hardy flowering trees, suitable from its neat bushy habit, handsome foliage, and gorgeous flowers, for planting on a lawn as a specimen tree, or for grouping among evergreens and other flowering shrubs, small trees in borders, or clumps, in the best kept grounds. *Æ. r. coccinea*.—This is a variety with flowers of a deeper red colour than the parent. It is a distinct and very beautiful tree.—“The Gardener.”

THE DOGWOODS.

TREE planters in search of novelties need not look far from home to find many really good things, especially in the way of hardy-flowering shrubs. Among these the Dogwoods hold a conspicuous place, although it is a rare sight to find any of the various species in cultivation, excepting a chance specimen of the common Large Cornel (*Cornus florida*). This showy plant, or rather small tree, is exceedingly attractive, owing to the large white leaves of the involucre, which are generally mistaken for the true flowers; they are merely the floral covering, the true flowers being of a greenish colour, and massed closely together in a head or cluster. The foliage changes to a brilliant crimson in the autumn, and the bright red fruit is very ornamental. A closely allied species to the above, and one that is equally deserving of culture, is known as the Dwarf Cornel (*C. canadensis*). This, which is really little more than a herbaceous plant, only grows 5 or 6 in. in height, from an underground creeping stem, with mostly four or six roundish pointed leaves, arranged in a whorl, as botanists term it. It is likewise very attractive when in bloom. Other species may be enumerated as follows: Panicked Dogwood (*C. paniculata*) a kind with pretty white flowers in a panicle, or (as it is called) a cyme; succeeded by pure white fruit. The Round-leaved Dogwood (*C. circinata*), forms a handsome shrubby plant with its large roundish woolly leaves, and light blue fruit. The Alternate-leaved Cornel (*C. alternifolia*) quite frequently makes a small tree of 15 or 20 ft. in height, with greenish striped branches, and dark blue fruit borne on reddish stems. The Kinn-

innik (*C. sericea*), sometimes called the Silky Cornel, is found growing in low, moist situations, and is easily distinguished by its reddish branchlets, round leaves, and light blue fruit. The Erect-growing Cornel (*C. stricta*), is not especially attractive, although worthy of a place in a group. Its branches are red, leaves ovate and smooth, and fruit pale blue. It belongs to the more southern parts of North America. The Red Osier Dogwood (*C. stolonifera*) appears to advantage in a collection; it has bright reddish-purple shoots, with ovate roughish leaves whitened beneath, and white fruit. It multiplies itself freely by means of suckers produced by numerous underground stems. The Rough-leaved Dogwood (*C. asperifolia*), unlike most of the genus, grows in dry sandy soil, the brownish coloured branches being covered with a rough pubescence; the leaves are long, pointed, and downy. The most beautiful of the genus is, however, the species found along the Pacific coast, called Nuttall's Dogwood (*C. Nuttalli*), a kind which forms quite a large tree in favourable localities; it has exceedingly showy, large involucres, followed by very brilliant scarlet fruit borne in dense close clusters. Its leaves are much larger than those of any other species, and the tree always forms a striking object in its native forests. The Cornelian Cherry (*C. mas*), is always a favourite on account of its bright scarlet fruit. It is a native of Europe. A variegated form of it is in cultivation. The Red-twigged Dogwood (*C. sanguinea*) is also a European species; it has deep red branches, greenish flowers, and purple bitter fruit. The White-fruited Dogwood (*C. alba*), known in the nurseries as the Red-twigged Dogwood, has bright scarlet bark on the young branches, and pure white fruit. It is a desirable ornamental shrub.—“Arboriculturist.”

The Ailantus.—This, as an ornamental and shade tree, has of late years fallen into disrepute on account of the offensive effluvia of its male blossoms; its planting in Washington has been forbidden by an Act of Congress—at least an appropriation for the district of Columbia, made some years ago, was granted upon the condition that no Ailantus trees should thereafter be planted in the city of Washington. The tree is, however, one of great value as a timber tree. It is one of the largest trees known, being said to attain a height of 300 ft. in China. Little attention has been directed to its medicinal virtues; but, according to Dr. Robert, of the French naval fleet in the waters of China and Japan, the bark of the root, in the form of a powder, is more efficient in the treatment of dysentery than ipecac, calomel, astringents, or opiates.

Shelter for Wellingtonias.—Although the Wellingtonia withstands the severest frosts with which we are visited, it is greatly benefited by shelter from the full force of the wind. We have many specimens planted in both sheltered and exposed situations, and while the former retain a fresh verdant green the whole season, the exposed ones have a seared and rusty appearance in spring, which, if not the result of permanent injury to the trees, is undeniable proof of their growth being checked, as the sheltered ones soon surpass the others in height. But, in providing shelter, great care must be exercised that it is not overdone, or the trees will become drawn up and weakly, and the side-shoots thin and wanting in vigour. The most perfect specimens that I have yet seen have been growing on soil rather poor than rich, which is doubtless accounted for by the roots influencing the character of the top growth, as rich soil and rapid growth induce a somewhat straggling habit, while poorer soil of a fibry nature produces a corresponding densely furnished habit of growth.—J. GROOM.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

The Weeping Chinese Cherry.—This (in nursery nomenclature *Cerasus pendula f. rosea*) is a singularly beautiful small weeping tree, with slender drooping branches clad with delicate rosy flowers. There is a specimen in the Exotic Nursery, Tooting. There are also good specimens of the large-flowered Almond (?) (*Amygdalus macrocarpa*), which, from its very large and firm flowers, deserves a place in every collection of early-blooming trees.

Sweet Acorns.—I have met with two Oak trees, one in Windsor Great Park and the other in Richmond Park, the Acorns of which, when perfectly ripe, are quite as sweet as Filberts, and I am persuaded that few people would know the difference. The Acorns are small and rather long, and the foliage of the tree very unlike that of any other Oak. I am not aware (says Mr. Jesse, in his “Scenes and Occupations of Country Life”) that this variety has been noticed by any writers on trees.

Flowers of *Choisya ternata* a Substitute for Orange Blossom.—This trifoliolate evergreen Mexican shrub, of which an example may be seen trained on a south wall in the Wellington Road Nurseries, is perfectly hardy in sheltered situations near London. It is nearly allied to the Rue family, and bears panicles of white flowers, in general appearance not unlike Orange blossoms, for which, when the plant is forced, they may some day form a substitute. Continental nurserymen use its flowers largely in a cut state for decorative purposes, and we see no reason why the plant should be less valuable for forcing than *Deutzias*, *Daphnes*, and shrubs of a similar kind.—B.

RAISING MYRSIPHYLLUM FROM SEED.

THIS interesting plant, commonly known as Smilax, from the Cape of Good Hope, is, according to the "Gardener's Monthly," now largely used in American cities for indoor decoration and also as a green for bouquets. It is easily raised from seeds, which should be sown in boxes of light but rich soil in August, and placed in a close shaded greenhouse. Of seed sown in two boxes, one that we placed in a close house germinated well, while that in the other, put in a hot-bed in which the heat was 95°, remained for eight weeks, and only five or six of the seeds germinated. Thinking the greater part of the seed had decayed, the box was taken out of the hot-bed and placed along with the first box, when in less than a week every seed germinated and grew at a rapid rate, soon outstripping that in the first box. When plants in 2-in. pots, placed in a warm house, and kept growing until early spring, when they require rest; for, it must be remembered, that they belong to the Lily family; after gradually drying them off, place them under the bench, turning the pots on their sides. About the first of August they will begin to show life by throwing up long slender shoots, of a pale purple colour, looking somewhat like Asparagus. At this stage they want planting out or potting; if they are desired for cutting, by all means plant them out, as they are great feeders, and want plenty of room and plenty

Sprays of Myrsiphyllum.

of water to bring them to perfection. Plant them in soil composed of two parts rich manure, two parts good loam, one part old turf, and one part sand; give plenty of water, never allowing them to become dry; their two greatest enemies are drought and red spider, either of which causes them to drop their leaves, and then they are worthless. Each plant will throw up six or eight shoots, and will need strings to hold them up; twine three or four shoots to one string, and when they have grown to the height of 5 or 6 ft. they are ready for market, each string being worth at wholesale about a shilling. After all are cut, dry them off gradually, and give them a slight top-dressing of manure. Each following year they will increase in value, throwing up more and stronger shoots. While growing, they should be often syringed, and occasionally watered with weak liquid manure. The second winter they will flower and produce seed. The flowers are greenish-white and, though small, very fragrant. The fruit is a berry, which grows to the size of an English Pea, and when ripe—in August—is a light red colour, containing three or four seeds, which are hard and black.

Aucubas as House Plants.—These are probably the most useful of all shrubs for rooms, corridors, &c. A group in Mr. Parker's house at Tooting, standing in a large window, has grown for three years without a check, and set and coloured their fruit freely, the flowers being fertilised by a small male plant placed on a shelf near. The fine and now greatly varied foliage of the Aucubas, and their easy culture, should make them very attractive for houses in towns.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Bedding Plants.—Where any deficiency yet exists of soft easily propagated plants, such as Heliotropes, Verbenas, Fuchsias, or Ageratums, more of these should at once be put in, the free-growing tops of the earliest struck cuttings that have been already boxed or potted off will strike readily, and if well attended to make better plants by the time for bedding-out than weaker cuttings that were put in earlier. Amateurs who have at command a plentiful supply of leaf-mould should mix it in the proportion of one-third to two-thirds of loam, in which compost they should pot their newly-struck bedding plants; but should there be a scarcity of leaf-mould, thoroughly decomposed manure, such as old hot-bed material, is the next best substitute. Any bedding plants that do not grow freely will be much benefited by manure-water, as filling the beds early in the season, and making a lengthened display, will materially depend upon their not being in a stunted condition at the time of planting out. Where fresh horse-manure is continually procurable, it will be ample for making manure-water; such not being available, amateurs will find nothing better than good guano, used at the rate of a dessert-spoonful to a gallon of water; if as much be made at a time as will last for a week, and a handful or two of soot be added to it at the time, it will be found much better than preparing it as it may be required; by letting the mixture stand for a few days, any offensive smell will be so reduced that it may be used to plants in rooms without any inconvenience. Its beneficial effects will surprise those who have not tried it, especially upon room-plants that have not had their soil renewed for a year or two.

By its use Polargoniums of all kinds, Hydrangeas, Fuchsias, Campanulas, Vallotas, Ferns, Lycopodiums, Palms, and similar subjects suitable for room cultivation, and which, if well attended to, may be kept in a healthy condition for years, instead of being thrown away after a short time; this is especially in the case of flowering plants, for which an annual shaking out and a replacement of fresh soil are frequently thought indispensable; whereas, if they were regularly supplied with manure-water from the commencement of their growth in the spring, they might generally be induced to flourish for two or three years, but little inferior to what they would in new soil; but, to make the system work successfully, the manure-water must be given as early in the spring as the plants commence growth, in order to supply food to the young roots as soon as these begin to form. Although it is advisable to gradually inure all bedding plants to the full influence of the open air before planting out, to prevent too sudden a check to their growth, and it is necessary to begin with the hardiest first, yet care should be taken that in this hardening process the plants are not subject to dry parching winds, and, above all, that they are not allowed to get too dry at the roots, which is the most likely to occur if they are in little pots; where this latter is the case, the pots should be plunged in ashes, or in many cases it is better to turn them out of the pots altogether, putting for that purpose in the pits and frames 4 in. or 5 in. of light soil, from which they can be taken up without much injury to the roots. Dahlia shoots should still, as they get large enough, be taken off and struck; these will succeed best singly in small pots. Where there is a deficiency of glazed lights to put those bedding plants under that are being hardened off, they may be covered at night and during cold wintry weather with thin canvas tacked to light frames, which can be taken off altogether on fine days.

Pits and Frames.—With the driving winds, drenching rains, and snows we have had during the last month, it has been more than usually difficult to keep up the requisite heat to Cucumber and Melon beds, which will make but slight progress unless a night temperature of 60° to 65° can be maintained. When the heat gets down to the lowest of the above figures, linings should at once be applied. The best plan after this time in the spring in making hot-beds for the above plants is to put them so that the frames will stand behind each other with about 4 ft. between, of course facing south; so arranged a lining of fermenting material betwixt them will heat both beds, retaining its heating properties much longer than if exposed to the wind on one side in the usual way; and after this time the sun gets sufficiently high above the horizon to prevent the front frame shading the one behind, as would be the case earlier in the season. I have had eight or ten hot-beds so placed, thereby effecting a great saving in labour and also in hot manure for linings. Some Melons should now be sown to put in frames after the bedding plants are out, as also some more Tomato seed.

Kitchen Garden.—The land will now be in better condition for sowing than hitherto, and advantage should at once be taken to fetch up arrears in both this and planting.

Peas.—More Peas should now be sown. Where suitable stakes are available there is nothing like the tall-growing varieties, not only for the greater quantity of produce they yield, but also for the much

longer time each sowing keeps bearing than is the case with the dwarf kinds, especially when they are not sown too thickly, and with enough space between each row. Peas, of whatever kinds, tall or dwarf, should now be sown much thinner in the row than was advisable earlier in the season, when it was necessary to make allowance for the destruction effected by both slugs and birds, as also through the seed rotting, to which it is always more or less liable with the early sowings—in fact, in many wet localities during the present season, early-sown Peas have disappeared almost entirely. Where such is the case, and only a few stragling plants come up, it is better to remove these altogether, and sow entirely afresh, than attempt to mend the rows, as the few that remain of the first sowing will come to maturity before the others, which will make a confusion of the whole.

Broad Beans, Cauliflowers, Cabbages, &c.—More Broad Beans should also be put in, as likewise early Cauliflower, and Veitch's Autumn Giant Cauliflower, autumn and winter-flowering Broccoli, Cottager's Kale, Green-curled Kale, Savoy, and summer Cabbages and Onions; where the ground has not been in condition for sowing before, Seakale, Turnips, Parsnips, Carrots, more Radishes, Lettuce, Spinach, and small salad.

Potato planting, if not completed, should be finished as soon as possible; a piece of ground ought to be chosen for this purpose that has been manured for a preceding crop, or else manure of a light mild nature should be used, such as rotten leaves or decayed vegetable matter from the refuse-heap. If there be a piece of old Strawberry ground that was broken up last summer after bearing and sown with Turnips, this will be most suitable for Potatoes, which will not only grow well amongst the decayed roots of the Strawberries, but will be less likely to suffer from disease than if succeeding a heavily-manured crop, such as Onions or Celery. In a well-managed kitchen garden, where the space will permit, the more Strawberries are grown the better, as they prepare the ground for culinary vegetables better than any other crop that can be grown.

Strawberries.—The ground between the plants should now be well hoed to destroy any annual weeds that are vegetating at the same time; such as Dandelions, or small patches of Couch Grass should be carefully got up by the roots. If one hoeing be not sufficient to kill all, give a second, so as to have the ground perfectly clear before mulching, which may now be done; this most essential operation should be carried out, whatever may be the nature of the soil, either light or heavy. The system that used to be all but general, and still practised by many—laying down straw or short Grass just before the fruit was ripe—is fallacious. The use of clean straw is wasteful, and assists the plants but slightly in a manurial point of view, while Grass is still worse; whereas if a good covering of stable manure that has fermented sufficiently for the straw to become discoloured be applied, it will act as a powerful stimulant that will increase materially the size and weight of the present crop, and will also greatly benefit the plants for another year, particularly in keeping the roots cool and moist through the summer by preventing evaporation; and when mulched with this kind of material about the middle of the present month, the manurial matter has time to get washed into the soil, leaving the littery portion clean for the fruit to lie upon equal to the best new straw. There is not much danger of overdoing the crop with thirty tons per acre, manuring their Strawberries generally at no other time and in no other way; it also effectually prevents the growth of weeds.

Stoves.

Many of the occupants of the above structures will now require shade of some kind, as the sun is becoming too powerful for such as have thin tender leaves, or object to bright light. When shade is applied thus early, it should only be for a few hours in the hottest part of the day, otherwise the young growth now being formed will become drawn and long-jointed, at the same time lacking that firmness necessary to produce satisfactory results when the period of flowering arrives. The material used to impart the required shade ought to be of the thinnest description, so as to break the sun's rays without obstructing too much of the light, plenty of which is necessary in the case of most plants subjected to strong heat abounding with atmospheric moisture. Tiffany forms a very suitable shade, but where it has to be used on rollers outside the house, the edges require binding with strong tape, or it soon gets rent by the wind. The most lasting material for outside shading is a kind of canvas known in the trade and sold by drapers as "strainer." This is a thin open material that affords plenty of shade, and as the threads composing it are made of the strongest fibre, it stands the tear and wear better than any other with which I am acquainted. Longer days necessitate a

marked increase of temperature, but this must in all cases be moderate and regulated by the amount of light at command. Take advantage of sunny days to close early, and damp well down by using the syringe freely over the heads of the plants and other available surfaces, that the moisture may be proportionate to the light and the extra heat applied. In cases where the general collection has to be treated in one house, it will be found necessary to make a separation of those plants that require shade from others that are benefited by a moderate amount of sunshine.

Crotons.—All the different varieties of Crotons require plenty of light to bring out their beautiful leaf markings that render them so very attractive. Light alone can develop these rich colours, and therefore they should be favoured in this respect as much as possible. When their natural colours are fully brought out, there is, perhaps, no more useful or ornamental occupant of the stove. For table decorations, small plants having single stems well clothed with foliage are as attractive as any that can be used for the purpose, especially such long narrow varieties as *C. inferruptum*, *Youngii*, *undulatum*, *Veitchianum*, *Weismanni*, and others of that class. Plants about 18 in. or 2 ft. high are the best for the purpose. After they attain that height, nip out the top close to the axil of the young leaf, in order that the wounds may heal over and not show. Any buds that start down the stem should be rubbed out as they show themselves, the effect of which will be to force the whole strength of the plant into the limited number of leaves, which will thus be developed to an unusual size, and the plants kept in the same serviceable condition suitable for small vases during several months in succession. The leaves, too, if kept clean and free from spider and other insects, brighten with age, and are thus more effective for decorative purposes. Larger plants, if grown freely now and gradually hardened off, may be used in the height of the summer in warm conservatories where their beauties are sure to be appreciated, as they look all the richer when seen in contrast with less choice subjects. Cuttings of any of these strike readily now if placed in strong bottom-heat, and kept close for a time. They do best taken off with a heel, inserting each cutting separately in a small pot, so that they may be shifted on without any disturbance to the young roots. Any that are pot-bound should at once be moved into pots of a larger size, that their growth may not be impeded, if fine specimens be desired. A free open soil, such as rough turfy loam and peat in about equal proportions, is the best in which to grow Crotons, and, as they require liberal supplies of water during the next few months, they must not be stinted for drainage. See that they are free from insects before they commence growing, as they will be difficult to eradicate without injuring the young leaves. Spider and thrips are the most troublesome, the former of which is often brought about through dryness at the root, but may always be kept in subjection by a free use of the syringe, and the latter by fumigations of Tobacco.

Dracenas are plants that also require plenty of light to develop their colours properly, and should therefore occupy a portion of the house not too much shaded, unless they can afterwards be placed in a better position to finish them off before they are required for decorative purposes. By an occasional watering with manure-water and keeping them constantly moist at the roots, they may be confined to very small pots without suffering in any way from the limited space afforded them. For general decoration plants with single stems are mostly preferred, but to be effective, they should be clothed with healthy, bright foliage almost down to the surface of the soil. Where any choice varieties have become naked and leggy, the stems should be bound round just below the leaves with some Moss or Sphagnum, which, if kept constantly moist, will soon induce them to emit roots, when the top can be taken off and potted in small pots. Plants so treated are at once ready for table decoration, and are far superior to such as can be propagated and grown in the ordinary way. Young plants generally have their lower leaves small and but indifferently coloured, whereas those on old plants have attained their full size and are then generally perfect in other respects. The beheaded stems can either be left to break again, or they may be divided into 2-in. pieces for cuttings, which, if subjected to brisk heat, will soon start into growth and form useful plants. *Dracenas* may likewise be increased by taking off pieces of the thick tuberous-looking roots that may generally be found in the ball of the plant, or amongst the cracks. The time of re-potting affords a favourable opportunity for removing any of these for the above purpose, as, with fresh soil, the roots are soon actively at work again, recovering quickly from any slight check they may have received.

Caladiums.—Where the stock of these is likely to be insufficient, any bulbs now started may be divided into as many pieces as there are crowns. By waiting till they break slightly into leaf this may be done without risk, provided they are kept dry for a short time afterwards to give the cut part a chance to heal over. Cala-

diums delight in a brisk bottom-heat, but when vigorous plants are required for decorative purposes, they should not be subjected to it for some time previously, or they soon flag when removed to more airy quarters. To get the leaves of good substance and develop their natural colours to the fullest extent, plenty of light is necessary, but this must be accompanied by a proportionate amount of moisture, both in the atmosphere and at the roots. If potted in loose open soil, such as rough peat or plenty of decomposed leaves and loam, with proper drainage and the requisite amount of heat afforded them, they can scarcely be overwatered while growth is active.

Cyperus alternifolius variegatus.—Plants of this have a very graceful appearance, either singly for table decoration or when associated with the brilliant-coloured *Dracona Cooperi*, groups of which, in combination with the above, are exceedingly effective. The variegated form of the *Cyperus* is very inconstant, as it soon reverts to the green state, especially if it receive liberal treatment inducing free growth. Poor sandy peat is the best material to pot it in, as the growth is thus kept within moderate bounds, and the variegation is more distinct. Being semi-aquatic, the pots should be well drained, that an abundant supply of water may be given them without risk of souring the soil. In dividing the roots or shaking them out for the purpose of re-potting, pull away any green portions that may be visible, or the variegated part will be starved and die out. A brisk moist heat is necessary, but if gradually hardened, they will stand in almost any position during the summer months where they can have plenty of moisture.

Achimenes.—The latest batch of these should now be started, and those already growing thickly in pans separated and placed about 1 in. apart in their flowering pots or baskets. Keep them well up to the light, so as to prevent them becoming weak and drawn, in which state the plants present a very weedy appearance, the flowers being but little more than half the size of those produced on well-grown stocky plants. Well-drained pots or pans, with rough fibry peat, or well-decomposed leaf-soil and loam in the proportion of three parts of the former to one part of the latter is the best in which to grow them. With the requisite shade, a moist atmosphere, and plenty of water at the roots, a satisfactory condition of these plants will be ensured.

Gardenias.—Cuttings of these should now be put in, and any young plants already rooted or requiring a shift should at once be potted on, so as to get them into useful flowering size as quickly as possible. Any that have done blooming may be pruned in at once, and the plants kept a little drier at the roots till they break again, when they should be shaken out and re-potted. Gardenias are very subject to scale and mealy bug, which are very difficult to eradicate while the growth is young and tender, or the plants have flower-buds on them. When pruned in, a good opportunity is afforded of getting them in a thoroughly clean state before they commence to start any of their dormant buds. The most expeditious way is to dissolve sufficient insecticide, and immerse the heads of the plants in the mixture, or to syringe them thoroughly over a tub or other vessel. This will be found much more effectual than hand washing, for, however careful it may be conducted, some part or other is sure to be overlooked, and these troublesome insects will quickly re-stock the plant. From 4 oz. to 6 oz. of Fowler's Insecticide, or Gishurst Compound will be required to each gallon of water to make it of sufficient strength to destroy scale or mealy bug.

Pelargoniums.—The pots of these being now well filled with roots, an increased supply of water will be necessary, or the plants will soon assume a sickly starved look that no after management will set right again. Without ample foliage, and that of a healthy green colour, Pelargoniums lose much of the attractiveness they possess when cultivation has been of a liberal character. All well-established plants, and such as are at all cramped for pot-room, should at once receive occasional assistance by giving them weak manure-water; this should be done once or twice a week, or even more frequently if drying weather prevail, rendering frequent applications of water necessary. In no case should it be given at all strong, as it is always better to apply it in a well-diluted state, and oftener, than to run the least risk of an overdose of stimulants at any one time. Nothing that I have ever used answers so well for the purpose as clear soot-water, to which about a table-spoonful or so of guano to a four-gallon pot has been added. This quickly acts on the plants by the ready way it is assimilated by them, and the soot-water has a wonderful effect on the foliage, imparting to it a healthy deep green colour, such as is not attained by the use of any other stimulant. As the bloom-buds will soon be developed, whatever lying or staking is necessary should be done at once, that the plants may have time to assume a natural shape and position before the flowers expand. Stakes as near the colour of the stems of the plants as can be obtained should be used, otherwise they are much too conspicuous, and detract

from the general appearance of the plants. Dried Willow or Hazel are the best for the purpose; but even with these, only what are absolutely necessary to support the branches in their proper positions should be used, as plants of no kind ever look so well if stakes predominate, and they be made to assume a too rigid, formal appearance. Green fly is sure to become troublesome at this season, and it will require great watchfulness to keep the plants clear of them. Fumigate the moment the plants appear blighted, and before the insects have time to become established, otherwise the plants will soon become crippled and disfigured.

Forcing Houses.

Choice Rhododendrons, hardy Azaleas, and plants of that class that have been forced and have now done blooming, should be re-placed in some of the houses where they can be kept well syringed in order to encourage them to continue and complete their growth in a satisfactory manner. From insufficiency of room, pressure of work, or other causes, it often happens that plants of the above character, after having been forced, get stowed away in positions where they stand little or no chance of setting flower-buds for another season's display, and fresh batches have to be introduced that require much more forcing to obtain them early. It is, therefore, good economy to keep all that have been forced under the protection of glass till such time as they have fully completed their growth, and the leaves have sufficiently hardened to withstand the weather without becoming disfigured by spring frosts, that are sure to affect them after having been subjected to a close moist atmosphere. Plants that have been forced a few times naturally acquire a habit of blooming early, and it is much less costly to prepare them at this end of the season, while the sun is enabled to give us the necessary heat, than it is to obtain it from the coal heap, when the days are short and vegetation sluggish. Continue to introduce the necessary quantity of plants to render the flower-house gay and afford the requisite supply for cutting. The beautifully-variegated *Acer Negundo* is a first-rate subject for forcing, as the delicate leaf markings are brought out in a very striking manner, and far superior to anything they ever attain under any other conditions. Standards of this are exceedingly ornamental when placed in suitable positions among dark-foliaged or gay-flowering plants, such as *Salvias* or others that have plenty of colour to contrast with the pure white margins of their handsomely-formed leaves. For drooping over the edges of flower-stands, greenhouse stages, vases, or similar positions, the Variegated Vine is almost unrivalled. This is greatly improved in richness; and delicacy of colouring by being subjected to the close moist heat of a stove or forcing house before being placed in a lower temperature. Treated in this way it is one of the most beautiful plants in existence, by the side of which those grown in the open air bear no comparison whatever. In the flower vase for dressing with others in a cut state they impart a finish so light and elegant in appearance, as to be worth growing for that purpose alone. Cuttings of the young wood root readily at this season, and if planted and grown out during the summer they make fine subjects for lifting and potting up in the autumn, to be forced and used for any of the above purposes.—J. SHEPPARD, Woolverstone Park.

Kitchen Garden.

At last we have been favoured with a few fine days, and on light soils the main crops of seeds will have been sown, though on heavy clayey ground, by reason of the excessive wet, a suitable seed-bed could not possibly have been obtained; such ground should now be pointed over, and all seeds sown in drills and covered in with light soil, such as the siftings from the potting shed, intermixed with burnt vegetable refuse or leaf-mould. The main crops of Potatoes should be planted at once, giving them plenty of room; 3 ft. by 2 ft. from set to set may by some be considered a waste of ground, but we know from experience that the produce will be increased both in quality and quantity to a greater extent than if but half that distance be given. Take care that those on warm borders which will now be emerging through the ground have soil drawn over them, or are covered with litter whenever frost seems imminent. We have tried most of the American varieties, and have consigned them to oblivion as worthless, with the exception of Early Rose, Snowflake, and Extra Early Vermont; these kinds on our light soil have proved to be wonderfully prolific, and passable in quality, but will bear no comparison to such as the Old Ashleaf, Lapstone, Fluke, Paterson's Victoria, and York Regent. The autumn-planted Cabbages are now growing freely, and should be earthed up; any that are going to seed should be pulled up and others planted in their places. If new ground be selected for planting Cabbages at this season, drill them in deeply, so that when the requisite earthing up is finished, the whole plot of soil may be of the same level, that the plants may benefit to the utmost by all the rain that falls, which is of the greatest importance in a dry season. A general sowing

of Broccoli, Cabbages, Cauliflowers, Kales, and Savoys should now be made. We sow thinly in drills 1 ft. asunder, and then rarely have occasion to prick out, but transplant direct to their permanent places; indeed, when the ground has been at liberty, we have sown Brussels Sprouts in their permanent positions, and certainly never have had them finer than by this mode; of course a sharp watch must be kept for slugs—bran, put down in small patches and frequently renewed, is the best remedy. Broccoli will shortly be in season, and if there be any probability of a break in the supply, dig up these that are least advanced, and hang them up by the heels in a cool shed open to the north, where they will keep good for a considerable time. When Broccoli is cut, do not leave the stumps to impoverish the ground, but dig them up and prepare for another crop, such as Celery, Potatoes, or French Beans. A sowing of the latter may now be made on a border where protection can be given. The two best varieties are—Canadian Wonder (an immense bearer), and Osborn's Forcing (a truly wonderful Bean, either for forcing or open-air culture). Broad Beans are seldom in request after Peas and French Beans are plentiful, but where a supply must be kept up, a few rows should be sown about every three weeks. Earth up the earliest sown ones, and, if desired extra early, pinch out the tops when about 18 in. or 2 ft. high, and this will induce them to flower somewhat earlier. A constant succession of Peas is expected in every garden, therefore, sow at regular intervals such kinds as have proved best in former years; of course novelties should be tried, but regard them with suspicion till fully tested. Great advances have been made of late years in the improvement of Peas; still many of the old kinds can worthily hold their position with the newer kinds, and none more so than British Queen, Ne Plus Ultra, and Champion of England, and these sorts should be sown now. Successional supplies of Spinach and Radishes may be had by sowing between the rows of Peas, as indicated in a former calendar. Lettuces that have been raised in heat, and are sufficiently hardened off, may now be planted out. The richer the soil the quicker the growth, and therefore the crisper the Lettuce; another sowing may be made in the open ground. Blonde de Berlin is a Cabbage Lettuce that is not so generally known as its merits deserve; it is much superior to any other Cabbage Lettuce we have yet grown, and the same may be said of Sutton's Superb White Cos. If the herbery have not yet received any attention, let it be no longer delayed. Most kinds of herbs do best by annual division and transplantation, and the same remark applies to Sorrel, which should be commenced forthwith. With the advent of warmer weather, Asparagus will soon be ready for use in the open air, and should be looked over every evening to cut any that is ready, as a sharp frost would blacken, perhaps destroy it; sprinkle the beds with guano or salt, either of which is more than usually beneficial at this stage of growth.

Forcing Vegetables.

Forcing, in the full acceptance of the term, will now be nearly at an end, still, greater attention will be requisite in the matter of airing and watering to prevent, on the one hand, a spindly growth, and, on the other, a check through want of moisture. Potatoes, Carrots, Radishes, and other small seedlings, should have full exposure when the sun shines. French Beans prefer to be kept closer, but should have plenty of air in the early part of the day and be closed up in the afternoon to husband the sun's warmth; at the same time they should be freely syringed to keep in check red spider. Plant out Cucumbers and keep up the required heat by frequent renewal of linings; as soon as frames are at liberty, if not wanted for more important crops, they may be filled with Ridge Cucumbers, Gherkins, Vegetable Marrows, or Tomatoes, and as soon as the plants are well established, and all danger from frost is past, the lights may be entirely removed and stowed away for the season. All kinds of herbs may soon be had from the open ground; Sweet Basil is an exception, and being so tender and always in request, must still be grown under glass for some time to come.—W. WILDSMITH, *Heckfield*.

Tobin's System of Ventilation.—The question of ventilation by Tobin's process has lately been brought prominently before the public, and adapted to various public and private buildings with satisfactory results. The expense is almost nominal, as it is merely placing in a room a tube of about .5 ft. long and 3 in. to 4 in. diameter, which communicates direct with the open air. The effect is, that pure air is introduced without the slightest draft except immediately over the top of the tube, which can of course be closed at pleasure or regulated by an ordinary oven valve. Has this process been tried by gardeners in their glass-houses, and, if so, with what result? My own experience seems to point to its great value.—JNO. L. OLIVER, *Unbridge*.

THE LIBRARY.

BOTANICAL NAMES FOR ENGLISH READERS.*

LEAVING the study of botany out of the question, amateurs—and it is not too much to say many professional gardeners also—encounter one great source of difficulty in the pursuit of an otherwise pleasant recreation or calling, as the case may be. We allude to the botanical names of plants. Even those who can boast a fair knowledge of Latin and Greek are often as much in the dark as to the meaning of certain botanical names as their less fortunate brethren. The vagaries of some botanists in fabricating names are astonishing. Hybrid compounds of Greek and Latin words, transposition of the letters of the name of a known genus to designate a closely allied new one, and various other ingenious devices in this direction, have done much to bring botany into contempt and ridicule. Fortunately most botanists are now guided by sensible rules, and although we may not get rid of the absurdities of former offenders, we may at least hope to be spared the infliction of others. Names are necessary, and although our friends often say "we do not want to know the Latin names; tell us the English ones," our reply in nine cases out of ten is perforce that none such exist. To the inquiry why botanists do not give plants English as well as Latin names, we can only say that few of them would ever get into general use, and therefore such a course would only increase the existing confusion. Assuming, then, that a knowledge of botanical names is imperative, it becomes a question how they may be most readily acquired. In spite of the difficulties indicated, we think that no very great mental effort need be called into action to overcome them. By a series of associations, many growers, both amateur and professional, carry scores, nay hundreds, of names of varieties of florists' flowers and fruits in their heads; and these varieties are distinguished by differences almost inappreciable to many of the most acute botanist; clearly, then, with some aid to an association of ideas, the horticulturist could retain and understand many botanical names as well as he does the names of his Roses, Fuchsias, Pelargoniums, and the rest. In fact, it seems to us that the latter are more difficult to the average gardener, when, as is frequently the case, they are in either French, or German, or Dutch, because the pronunciation of words belonging to these several languages is only acquired by comparatively few people after the days of youth are past. With similar ideas in his head, Mr. Alcock has written a book, in which he "attempts to explain the scientific names of British plants in a popular manner, so as to be useful to those who have no knowledge of foreign languages." As far as he goes, we think Mr. Alcock has succeeded admirably; we only wish it had occurred to him to extend his work to the plants commonly cultivated. This need not have added greatly to the size of the book, and it would have increased its usefulness, and doubtless its circulation, in a very considerable degree. As it is, we can conscientiously recommend it to all those in need of some such assistance in mastering the names of plants. It bears the evidence of having been carefully edited, and the explanations are terse and to the point. Without being diffuse, the author is intelligible. For example, concerning the terminations of Latin adjectival specific names, he says:—"Taking them generally they are governed in this way: masculine, *us*; feminine, *a*; neuter, *um*; as acute-*us*, acute-*a*, acute-*um*;" according to the substantive name with which it may happen to be joined. In other cases, where the termination is *is*, it serves for the masculine and feminine genders, being changed to *e* for the neuter, as *gracilis*, *gracile*. We have, masculine, *niger* (black); feminine, *nigra*; neuter, *nigrum*; but such instances are not common, and where they occur they are written in full." But we are anticipating. We should explain that the book is divided into two parts; the first, comprising eighty-three pages, is devoted to a succinct history of botany and botanists. As may be imagined from its brevity, this is a very imperfect and incomplete sketch, in which only a few distinguished authors are mentioned. Some of the omissions are inexplicable. Thus Hudson, who we believe was the first

* "Botanical Names for English Readers," by Randal H. Alcock, 8vo, 236 pp. London: L. Reeve & Co., 1876.

to apply the Linnaean system of nomenclature in a flora of the British Islands, is not mentioned; much less could that "hortulanorum princeps," Philip Miller, of whose dictionary Linnaeus is reported to have said, *Non erit lexiæon hortulanorum sed botanicorum*, find a place. This part is supplemented by an appendix, containing some additional information respecting Turner, Gerard, Johnson, Parkinson, and Evelyn. The second part contains lists of all the generic and specific names (accented and explained) employed to designate our wild plants, and is far more satisfactory. Where there are two or more pronunciations, authorised by custom or derivation, they are given. Thus *Clématis* and *Clem'atis*, *Veronica* and *Veron'ica*, etc.; and the correct pronunciation of such names as *Erica*, *Arbutus*, *Enothe'ra*, and *Umbilif'ous*. A few slips occur, which we point out with no wish to find a fault. Thus *gigant'ous*, the customary though incorrect pronunciation, is given, and not *gigant'us radicans*, and not *radicans*; *hy'brids*, and not *hyb'ridus*; and *rufus* and *ruber* (red), and *lutens* and *flavus* (yellow) are given without any explanation as to the different tints they are intended to designate. But these few exceptions prove the general excellence of the work. In conclusion, we again recommend it, because, as far as it goes, in regard to the pronunciation and meaning of plant names, it is the most reliable authority we know that is accessible to every one. W. H. HEMSLEY.

EFFECTS OF NOXIOUS VAPOURS ON LONDON GARDENS.

In speaking in the House of Lords, on the motion for appointing a Royal Commission to inquire into the working of manufactories emitting noxious vapours, the Archbishop of Canterbury made some remarks that are much called for at the present time. It must strike everybody, he said, who had known the metropolis for a good many years that the gardens which used to be the glory of the neighbourhood of London were fast disappearing, and that those beautiful Cedars which were seen in the neighbourhood of London more than in any other part of the kingdom were fast washing away. It was equally true that the rich people who used to live in the suburbs of London were going further out. In a report of an official character, strong reference was made to a state of things which existed within a few minutes' walk of their lordships' House. It is stated that along the Lambeth Embankment, between Vauxhall and Lambeth Bridges, there were works which were highly injurious to the health of the inhabitants of a very crowded neighbourhood. The trees died on that Embankment, and he was informed that the Local Board had determined not plant any more trees there. Their lordships, who were able to live in large and healthy houses, enjoyed the satisfaction of feeling that they might enjoy comparative immunity from noxious vapours and gases, and he himself, though dwelling in Lambeth, had the advantage of a spacious house with a large garden, and had the further advantage of being able to go in the country when he liked to do so; but let their lordships think of the thousands of poor, who, living in such a neighbourhood, were shut up in their narrow lanes and crowded houses from morning to evening and from evening to morning throughout the whole twelve months of the year, always breathing the atmosphere created by those neglected manufactories and heaps of manure. It must not be supposed that he did not enter into the feelings of the manufacturers. No one could have visited the Pottery Works over the river, and seen the wonderful articles sent from there to Philadelphia, without fully recognising how much good was done by these works. No one could say that because they suffered from the vicinity of a candle manufactory they did not appreciate the advantage of having bright lights and beautiful wax candles. Nor did they object to manure in its right place, but that place was not within a few minutes' walk of that House and of his own residence. What they complained of was, not that these things were done, but that proper care was not taken in the doing of them. Were they to believe that modern science could not find some remedy for these evils—that some of those gentlemen who were receiving liberal salaries for carrying on their researches could not find some way of at once preserving our health and carrying on the civilising arts in a flourishing manner among us? Manufacturers had no vested right to destroy our health in order that they might minister to the progress of the arts which they had introduced into this country. He hoped the inquiry would be granted, that it would be extended to the metropolis, and that as soon as possible legislation could rescue a large portion of the community from the evils under which it at present laboured.

Ripening of Pears.—It may be interesting to Mr. Gilbert and others to know that the northern and midland districts do not stand alone this season as regards the uncertain ripening of pears. With me, Marie Louise, Napoleon, Passe Colmar, Beurré de Capiaumont, Seckel, and Glou Moreceau have been very good, especially the two last-named kinds, but Glou Moreceau has been the best Pear of the season; of this a heavy crop from a pyramid commenced ripening in December, and has furnished a succession till March 30. On the other hand, Winter Nells, Beurré Diel, Chamaumont, Husbelt Prince of Wales, Winter Crassane, and Knight's Monarch have not ripened well, and even now (April 4) Knight's Monarch is tough and hard. The best showing Pear this season has been Bezi d'Heri. With the exception of Winter Crassane and Chamaumont, all were grown on pyramids, bushes, or espaliers, within forty miles of the south coast, and on a southern slope not more than 180 to 200 ft. above the sea-level. Soil, light sharp loam, substratum, rock known as Kentish rag-stone.—W. DIVERS, *Wierton, Maidstone*.

Fruit Prospects in West Middlesex.—Another fruitful year is apparently in store for us, if we can but overcome the late spring frosts, which are always the terror of fruit growers. Apricots, Peaches, and Nectarines are blooming profusely, and, as far as my own trees are concerned, although not protected, the blossoms are uninjured. On an Apricot tree, recently literally a sheet of bloom when the weather was at its worst, hundreds of fruit have set, although the flowers looked as though they had been burnt. Probably too much protection tends to coddle and weaken the fertilizing organs of the flowers. Gooseberries and Currants are in full flower, and, if no injury follows, there will be a heavy crop of each. Some of the early standard Plums are already in full bloom, and on later sorts the buds are thickly set, even on trees that were over-weighted with fruit last year. The same might be said of Apples and Pears. Heavy crops, such as were gathered last year, are not all profit, as much fruit, owing to its abundance, gets wasted, and unremunerative prices are obtained for it.—D.

Souvenir du Congrès.—This new and remarkable variety was exhibited by us for the first time in September, 1873. Then, on account of its large size, fine form, superior quality, and earliness, it attracted greater attention than any other variety. The tree is an upright pyramidal grower, vigorous and very productive. The fruit grows sometimes singly, but generally in clusters of two and three from the same bud, and hangs firmly to the tree when exposed to influences which cause other varieties to drop. It weighs from one to two pounds, and it is larger than the Bartlett or Clapp's Pavorine, to which it bears a strong resemblance. The skin is smooth, bright yellow, when the fruit is fully matured, with the parts exposed to the sun a brilliant red or carmine. The flesh, while it is very like that of the Bartlett, has a less defined musky flavour, and it is firm to the core. It commences to ripen about the 1st of August, before the Bartlett, and extends into September. We cannot too strongly recommend this as one of the greatest acquisitions to our lists of new and fine Pears.—ELLWANGER & BARRY.

House Sewage (see p. 307).—For upwards of fifty years sewage has been utilised here as follows:—All shearings of hedges, prunings of fruit trees, and any rubbish that will burn are collected together into a heap and kept smouldering for weeks, by being continually earthed up, in order to make as large a quantity of wood-ashes and burnt earth as possible. This burnt material we bank up and keep dry until November, when it is carted to the cesspool and made into a large basin or cavity, several inches thick at bottom, with good thick sides built up to the required height; the cesspool is then emptied into it, and the sides are turned in so as to form a heap, the ashes absorbing all liquid and sediment. The heap is then well banked up and allowed to be undisturbed for about a week, when it is used as a dressing for Asparagus beds, the produce of which for the last half century has never been equalled in Devonshire.—JOHN GARLAND, *Killerton, Exeter*.

Slugs and Wasps.—I am curious to learn if any of your readers have remarked the extraordinary numbers of slugs this season. In the absence of any other reason, I am inclined to attribute it to the excessive rainfall of last year. Writing of garden pests and pilferers reminds me that I caught the first wasp I have seen on the 3rd inst., and to those who like myself do not admire or appreciate this interesting insect, I would urge the adoption of my plan—which I have practised with marked success for many years—viz., of offering a penny for each wasp up to the middle of June. Our village school children are keenly alive to this, and keep an active and anxious look-out for them. I must confess, however, to having been a little taken aback one day last spring when a boy brought me seventy-four in a ginger-beer bottle!—WINCHMORE.

30,000 TREES were blown down in the Forest of Compiègne by the tornado which passed over Normandy a few days ago.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

APRIL 8TH.

THE subjects of exhibition on this occasion were somewhat limited in number; but amongst them were one or two of especial interest. The new white purple-spotted *Odontoglossum cirrhosum* was shown in admirable condition by Mr. Spencer Brunton, of Beckenham, and is in every way a desirable addition to this popular group of Orchids. It is one of Mr. Bull's recent introductions, dried specimens of which we have recently seen, bearing over twenty flowers, on tall branching spikes. Messrs. Veitch & Sons sent their new Fern, *Adiantum digitatum*, which is one of the most graceful of all the Maiden-hair kinds, and several other novelties, to which we allude elsewhere. The Rev. J. T. Boscawen contributed fruit of a Cucumber which he had perpetuated from cuttings for 13 years, and which was said to be perfectly seedless, and of very superior flavour. A singularly-fasciated underground branch of *Jasminum revolutum* was exhibited by Mr. Kinghorn; and Mr. Paul furnished a plant of the purple-leaved Birch, which had been grafted on the common green-leaved form. The grafted portion of the purple-leaved kind had originally three buds; after the lowermost one of these started into growth, the two uppermost were cut off, and from the scars thus produced masses of perfectly green adventitious twigs and leaves were produced. Several large stands of cut Roses came from Messrs. G. Paul & Sons, of Cheshunt, one being filled with large, full, and superbly-coloured blooms of *Marchal Niel*.

First-class Certificates.—These were awarded to the following new and rare plants:—

Adiantum digitatum (Veitch).—A distinct and graceful new Peruvian Maiden-hair Fern, which, together with the following *Rhododendron*, was certificated by the Royal Botanic Society last week; of both of these descriptions will be found at p. 324 of our last week's number:—

Rhododendron Princess of Wales (Veitch).—A cross between *R. Lobbiai* and *R. Princess Royal*.

Clematis President (Noble).—A beautiful large-flowered spring-blooming variety of robust habit and a decided merit, the result of an attempt to increase the deep colour of the autumn-flowering *C. Jackmanii* type into the early-blooming section. Its flowers measure about 7 in. in diameter, and consist of eight stout, well-formed, and much-lobed sepals of a vivid bluish-purple colour. It forms a beautiful addition to the early-flowered section of this deservedly popular genus.

Odontoglossum cirrhosum (Henley).—This is one of the best of all *Odontoglossum* of recent introduction. Its slightly compressed one-leaved pseudo-bulbs are clustered along a scandent rhizome, and the flowers are borne on a slender branching spike, about 18 in. in height. Imported specimens of it show from twenty to thirty flowers, and the plant exhibited bore about a dozen of a pure white colour, conspicuously spotted with chocolate, inclining to purple. Its sepals and petals are ovate with a much undulated margin, their apices very much elongated into tail-like extremities, while the lip is three-lobed, the lateral lobes being serrated or fringed, of a yellow colour, streaked with close brown lines, the apex of the central lobe being continued into a tail-like curved point. The largest blooms are fully 4 in. long, by about 3 in. in width. It is a plant which well deserves a place in even the most select collections.

Miscellaneous Subjects.—Messrs. Veitch contributed a choice group of Orchids, Ferns, and other decorative plants, among which we remarked *Odontoglossum Mulus*, a kind which looks like a dark and profusely blotched form of *O. gloriosum*; *Cattleya Veitchii*, a beautiful hybrid, raised some years ago by Messrs. Veitch—one which has dark glossy leaves of great substance, and from five to six flowered spikes. Its sepals and petals are rosy-lilac, the lip richly blotched with velvety crimson-purple. From the same firm also came a plant of *Dendrobium Wardianum*, bearing twenty-two flowers on a pseudo-bulb, nearly 4 ft. in length, and several other with a less number of flowers, the white sepals and petals being richly tipped with magenta-purple. Mr. B. S. Williams, of Holloway, showed a large and effective group of new and rare Ferns, Orchids, fine-foiled plants, and some brilliantly coloured scarlet-flowered *Amaryllis*. Messrs. Geo. Paul & Son furnished, in addition to four splendid boxes of cut Roses, several healthy and well-flowered little specimens of Roses in pots, of the most distinct of those being the salmon-tinted *Pen-scented* variety, named *Jean Ducher*, a kind which has glossy foliage and fine full flowers like those of the well-known *Gloire de Dijon* in shape, but distinct in colour. Emily Laxton (H. P.), also shown by this firm, is a richly-coloured variety, and the pale-blush or rosy H. P. *Comtesse de Serey*, promises to be a useful and beautiful addition to exhibition varieties. Mr. H. Bennett, of the Manor Farm Nursery, Stapleford, Wilts., contributed an effective stand of about a dozen cut roses in good condition, including several seedlings and the new *Rose Comtesse de Serey*. Mr. Gibbons, of the Gardens, Taplow Hill, Maidenhead, sent a collection of large and richly-coloured *Cineraria* flowers. Mr. G. F. Wilson contributed a basketful of choice *Primulas*, among which we observed well-flowered plants of *P. ciliata*, having Auricular-like flowers of the richest crimson-purple; and *P. intermedia*, a kind which has deep purple flowers, rather smaller in size, but with a more conspicuous yellow eye; *P. purpurea*, also shown in the same collection, had neat rugose-oblong leaves and erect scapes 10 in. high, of bright lilac

flowers borne in dense globular heads, the upper portion of the scapes being farinose, but without the least trace of meanness on the foliage. Mr. F. Sanders, St. Albans, showed an example of the new *Primula Roezlii*, from Japan, a kind having *Cineraria*-like foliage and pink flowers, borne on slender hairy scapes. Mr. Harrison Weir sent a strong-growing variety of *Myosotis sylvatica* named "Weirleigh Surprise," a novelty having terminal clusters of white flowers, each division of which is conspicuously striped with porcelain blue. Colonel Trevor Clarke showed a double *Primrose*, raised at his place at Welton; it has flowers like those of the old double lilac, but they are borne on short-stalked umbels like those of a *Polyanthus*. The same exhibitor also furnished other fine seedling forms of *Polyanthus-Primroses*, some with white or creamy-yellow flowers and rich orange centres being very pretty. Mr. Ollerhead, gardener to Sir H. Peck, of Wimbledon House, sent a group of Orchids and other plants, the most interesting among them being five large baskets of a strong-growing *Lachenalia* named *L. pendula*, the drooping foliage and blossoms of which completely hid the basket. In the same group we noticed a healthy example of *Lycopodium Phlegmaria*, a plant with a graceful habit, having pendulous *Epacris*-like stems terminated by fresh green tassell-like fertile fronds. Messrs. Barr & Sugden furnished some fifty varieties of *Daffodils* and *Narcissis*, among which we noted *N. Macleai*, *N. cernuus*, *N. moschatos*, *N. minor*, and *N. nanus*, the three last-named being the smallest of all *Daffodils*, just as *N. major* and *N. maximus* are the largest. *N. incomparabilis* and the sweet-scented *N. odoratus* were also represented by several distinct single and double flowered forms of each. One of the rarest of all double *Daffodils*, *N. pseudo-Narcissus fl.-pl.*, was represented by three fine blooms, and its ally, *N. Eystettensis*, of Heberich, is very interesting also, as having the segments of the corona entirely separated, and those of the perianth arranged in six rows, something like those of a *Lady Hume's Blush Camellia*. Messrs. Fisher, Holmes & Co. again exhibited their new hybrid *Rhododendron*, *R. Fisher Holmes*, which has from three to five flowered trusses of white sweetly-perfumed flowers, each measuring from 3 in. to 4 in. in diameter. The foliage is of a deep glossy green colour, and the plant was highly commended, but was not considered quite distinct enough to merit a first-class certificate.

Messrs. Rivers sent a small collection of late Apples, and a well-flowered Cucumber came from the Hon. and Rev. J. T. Boscawen. Mr. Parsons, of Danesbury, Welwyn, showed half-a-dozen fine examples of the *Magnus Bonum Onion*, which in general appearance resembles James's Keeping or Brown Spanish, but is much larger.

NOTES AND QUESTIONS—VARIOUS.

Acubia Fertilisation.—The pollen in this case (see p. 318) has probably been distributed through the agency of bees. I have an *Acubia* in my garden which has borne the nearest male plant (it is about 20 yards off. I keep bees and attribute the cause of fertilisation to them.—S. B.

The Cow Pea.—A plant is cultivated very largely in the Southern States of North America under this name. It now occurs in a good many varieties, the seeds of some of which are figured in the "American Agriculturist" for April. Its name is *Dolichos sinensis*, and it is supposed to have been long in cultivation in China and Cochinchina.

Seakale and Rhubarb at Christmas.—Ought not a garden, well supplied with stable manure and with a staff of four men, to afford a supply of Seakale and Rhubarb at Christmas?—P. S. N. [Undoubtedly, if there be any kind of structure in which the usual modern way of forcing these plants may be carried out.—W. T.]

Ficus minima hardy.—This delicate-looking and graceful little plant is apparently hardy. In Mr. Kinghorn's nursery at Richmond, it is cultivated in a warm house creeping closely over the wall of the same. Some of the shoots found their way through the bricks, and are now growing over the outer surface, having stood the winter and spring without injury.

Fruit Prospects in Northamptonshire.—All kinds of fruit, except Pears, are promising here. Pears, both on standards and on walls are very thin. Apricots, to which 700 ft. of south wall are devoted, have been quite sheets of blossom; they are protected with double fish netting; but I fear the early flowers have got frosted. Of Peaches and Nectarines we shall apparently have heavy crops. But of all places in which to grow fruit, give me cool lean-to houses.—R. GILBERT, *Bargely*.

A Simple Protector.—The "Fincastle Herald" has been informed "that a piece of iron hung in fruit trees will effectually prevent the ravages of frost. A piece of horse-shoe was hung in a Cherry tree in an orchard, and the yield was abundant; while in three adjacent trees the fruit was entirely killed."

Echeveria-eating Insects.—What is the name of the enclosed insects? They are making sad havoc amongst *Echeverias*, completely eating their roots off, and boring up the centres of the stems, so that on lifting the pots the plants fall over. I am burning the soil, in order to destroy them, if possible. [The pest of which you complain is the well-known *Otiorynchus notatus*.—A. M.]

Early Beatrice, Hales' Early, and Early Louise Peaches.—What is the experience of Peach growers with regard to the usefulness of these varieties, especially for early forcing? Will any of them shake the position of that old worthy veteran, the Royal George, as a first-rate Peach for forcing?—W. B. *Chesham*.

Missing Coloured Plates.—We learn that agents sometimes deliver THE GARDEN without the coloured plates. Every copy that leaves our office contains a coloured plate, and purchasers should refuse copies that do not contain the plate.

Coca.—This plant, which affords the leaf so much talked of recently, was, owing to a clerical error, mis-applied Coca in the last issue of THE GARDEN. As a well known, the two plants are quite distinct.

No. 230.]

SATURDAY, APRIL 15, 1876.

[Vol. IX.]

"This is an art;

Which does mend Nature: change it rather: but
The Art itself is Nature."—Shakespeare.

VIOLETS AND THEIR CULTURE.

By GEORGE LEE, Cleveland.

A CORRESPONDENT "R" (p. 238), in his remarks upon these fragrant flowers, truthfully says, "that few plants are more appreciated at this season of the year, by rich and poor, than Violets, and few are, as a rule, more neglected." Also, that "few people imagine that they can be improved by good cultivation; and, in preparing a bed for them, that the soil can scarcely be made too rich, provided it be open and well drained." With these statements I thoroughly coincide; but in the following directions, "that if the soil happen to be light and gravelly, some stiff material and plenty of manure must be added to it; and, if poor and hard clay, it will be benefited by the addition of some sharp, gritty matter and abundance of rotten manure," I believe that he has omitted a most important item as regards culture, viz., that "the stiff material," and "poor and hard clay," should be thoroughly pulverised before admixture with manure or gritty matter. My own impression, until lately, was that partial shade was most serviceable to the full development of Violets, founding my conviction at that time upon their natural habitats (hedgerows and woods), but subsequent experience has convinced me that a full exposure to the sun has benefited very materially both the quantity and quality of their bloom. Before I sent out the *Victoria Regina* Violet, I had the rooted runners taken up and "laid in" in some spare ground to the amount of some 30,000 plants. Many of these were allowed to remain in their "laid in" state over the summer, which was very dry. The soil was so thin and so fully exposed to the sun, that many of them had to be watered to keep life in them, and I expected that the show of bloom would be unsatisfactory; the results were, however, otherwise, for I had the finest possible blooms, as well as a profusion of them, and even now (their second blooming season) I have none to equal them. Of course the soil (what there was) had been made good for previous crops, and the plants had last season every attention paid to them during their growth in the way of removing all runners, and in July cutting off all the leaves, with an immediate plentiful dressing of soot; I have found that soot most effectually clears the plants from red spider, and acts as a stimulant for the loss of their leaves. It was on one of these "laid in" patches; of some 70 to 80 perches in extent, that I counted, some few weeks ago, 120 fully-expanded blooms to the square foot, about 9-10ths of which were erect, and perhaps not one of them less than $1\frac{1}{2}$ in. in diameter. Visitors from a distance frequently come to see them, and express their amazement at the size and luxuriance of the flowers. Previous to my experience as above recorded, my own impression, and indeed my expression in writing upon the treatment of Violets was just that of your correspondent, that "in deep rich soil they will bear a considerable amount of sunshine." As to the propagation of Violets they do well from cuttings, but the best method is by means of layers; it is more troublesome and expensive, but the plants thus obtained are far preferable to those produced by any other method. The trimmings of Pea sticks may be used as crooks for the runners in June and early in July, but as soon as the Fern (the common Bracken) is firm enough, this constitutes the best material for crooks, especially when Violets in quantity are required to be grown for market, as pots can be dispensed with altogether, and the plants give much greater satisfaction. Beds of plants should be set apart for runners—that is, if a good display of bloom be desired; as runners much impoverish the parent plants if allowed to remain on them. The second year the plants must be well cleared of runners several times during the growing season, the effect of which will be to materially improve the blooms both in colour and texture. The end of February or early in March is a better time for inserting cuttings than April, as then (except in the

north) one does not need hand-lights and covering. Then as to planting, I used, like your correspondent, to plant in 4 ft. beds, three rows in a bed; but I now plant the beds transversely, which I find much better, especially if protection be used for the beds in severe weather. Make the beds run east and west in order that the rows may receive the full benefit of the sun in the winter and early spring months. Plants that are allowed to remain more than two years in the same bed yield but few blooms till February and March, and these are not equal to those on younger plants. It is my opinion that taking up and dividing the plants is a most barbarous method of increasing one's stock; it may succeed for a few varieties, such as *V. alba compacta* and some other double ones, but the plan should be avoided as a rule. I have not mentioned many varieties of Violets, having done so in previous papers on their culture; I however created some discussion about two years ago when I wrote favourably about the old Russian, respecting which I have now no reason to alter my opinion, which was to the effect that there was no Violet to supersede it for winter blooming and profusion of flowers, although its period of flowering was much shorter than that of many others not so early or so late; then there is Russian Superb, which comes in quantity the earliest of all, but it is soon over. Neither variety can be grown profitably for the market, the stems being too short, while their shape and size are also prejudicial to their sale; but for an amateur, either for pot culture, or in the open border, the old Russian is a most compact and desirable kind. As to the Czar, I am of opinion that it is a distinct variety. The Tree, the King, and other double blues, are mostly well known, but *Brandyana* is not so well known as it should be; neither of these suit me as market varieties, but the last for an amateur (as a spring-flowering kind) is most desirable, being a profuse bloomer; from forty to sixty fully expanded blooms of it might be covered by the open hand, and their beautiful markings make them most attractive, being white, bright purple, and blue beautifully striped with other shades. The white of the Hedge-row is much improved by culture, as your correspondent very truly observes. Some of your readers may very likely say—why all this about Violets? About twelve years ago, when I began cultivating Violets for market, I searched in vain for anything like a treatise on their culture, and as those of your readers who took an interest in the "see modest flower" may have been equally unsuccessful when seeking for information, I trust I may be pardoned for giving the benefit of my experience in its culture, which may not be the less trustworthy from having acquired my knowledge by frequent, and in some cases serious, failures: for example, till about sixteen months ago I was of opinion that the planting season of Violets might be in any open weather from the beginning of October or end of September to the end of March; but I found, to my most serious cost, that I had made a mistake, and my beautiful *Prince Consort* was the victim. They had been planted in large quantities a few days only before the occurrence of severe frost, from the effects of which they have never recovered; and till even a later period I advocated a deep soil, but again I find that I have been mistaken, and *Prince Consort* is again the sufferer. A rich, thoroughly-drained soil is absolutely necessary for success. In some of my previous papers on the culture of Violets, I stated that the soil, when not well drained, should be taken out to the depth of 2 ft. or more, half filling the space with stones; I would recommend the planting of the stones in the form of a ridge, allowing it to rise some 16 in. or 18 in. above the surrounding surface, and placing the soil on the ridge to the depth of 10 in. or 1 ft.; the width should be 5 ft. or 6 ft. running east and west, so that the ridge faces south and north. No language can describe the beauty of *Victoria Regina* in my grounds this season. Imagine a bed covered with bloom (from 100 to 120 or more in a square foot) of fully-expanded flowers, scarcely one being under $1\frac{1}{2}$ in. in diameter, and this continuing for some weeks; together with a quantity of bloom from the end of August till the end of March or middle of April, and what can be more desirable in the way of flowers? Violets may be grown in pots in a cold pit or frame, for furnishing the conservatory or greenhouse, and to great advantage through December and January. The plants should be from the earliest runners, two to four in a pot, layered in June and taken up and potted

early in September; they should be kept in the open ground till the end of October, and then plunged in Cocoa-nut fibre within about 8 in. of the glass, with the lights off every fine day (except it be frosty); even when wet they should have plenty of air so as to prevent drawing; divide them in three or four sets of, say, six to twelve or more each, according to space to be appropriated by their use, and allow each set to occupy the conservatory for a week or ten days, replacing them in the pit till it comes to their turn again. In this way compact growth and perfect health are maintained.

TREES AND SHRUBS FOR EXPOSED SITUATIONS.

Those who live in high and exposed situations have difficulties to contend with in furnishing their gardens, of which people who live in sheltered valleys and in the low lands know nothing. Low-lying districts undoubtedly experience the severest frosts, which are bad enough, but they are a moderate evil compared with persistent and cold winds, which starve and retard vegetation more than all other causes put together; and I speak from considerable experience in the matter. I am acquainted with gardens and parks situated many hundreds of feet above the level of the sea, where the effects of exposure on the one hand and shelter on the other are strikingly contrasted. In some of these instances the demesne may fitly be compared to a circle planted in concentric rings; the outer circle, being most exposed, is stunted and poor; the next is better; and, as we approach the centre, the trees improve both in height, girth, and luxuriance, the result simply of the shelter afforded by the other outer rings, which break the force of the blast. On one high-lying estate, exposed to the north and north-west winds, it is found that such trees as Wellingtonias and some of the more tender Conifers positively refuse to grow anywhere but in the sheltered glades of the woods. Planted in the open park, they will not thrive. The Wellingtonias were protected for the first few years by close palings some 5 ft. high; and, nursed in this way, they made densely-furnished little trees; but, as soon as they reared their tops above the line of shelter, their disfigurement began, and the attempt to grow them had to be discontinued. In the low country, however, not many miles away, and on the same formation, the same Conifers thrive amazingly. Much disappointment would be avoided if, in planting exposed sites, suitable subjects only were selected; for, although all specimens are affected, more or less, by exposure, there are many trees and shrubs that will thrive tolerably well if they get a favourable start. The following subjects I can recommend, from personal observation, as likely to grow and reach a fair size at an altitude of from 600 to 1000 ft. above the sea-level, as far north as the midland counties at least. Along the "backbone of England," and on other high-lying tracts, there are many residences situated at or near these elevations, where planting for shelter would be very desirable if it could always be carried out successfully.

DECIDUOUS TREES.—Among these the following will be found serviceable:—Horse Chestnut, Sycamore, Oak, Beech, Double White and Scarlet Thorns, Laburnum, Spanish Chestnut (a good grower), Elm, Poplar, Willow, Birch, Mountain Ash, Gean or Wild Cherry, and Crab; the Lime succeeds also, but is liable to be disfigured by having its limbs blown off by the wind. As an undergrowth, the Hazel and Elderberry will be found excellent for forming an almost impenetrable thicket.

EVERGREEN TREES.—Among these Conifers rank first. The Scotch Fir will grow almost anywhere, but for shelter the common Silver and Spruce Firs are unsurpassed. If the soil be tolerably moist and deep, they grow with great rapidity in the bleakest situations, and in a few years form a dense covert. It is not advisable to plant many of the ornamental Pines, as they get thin and weedy in habit as soon as they grow to any size; at least, I never saw a handsome Conifer in an exposed situation, except P. Nordmanniana and the Deodar. These two are well worth planting, especially the latter, which grows and forms a fine symmetrical tree where few of the others will thrive. The Araucaria imbricata and the Cedar of Lebanon are the next best. The Araucaria is dwarfed by exposure, but

it grows and retains its symmetry. Some of the oldest trees of this species in the country grow at an exposed altitude of 650 ft. or more, and have escaped all the severe frosts of recent years. Cupressus Lawsoniana and the hardier varieties do fairly well, and attain a good height; also the Irish Juniper, the Thuja, and last, but not least, the common English Yew and the common Holly, both of which should be planted extensively.

EVERGREEN SHRUBS.—Many of these will live on exposed sites; but I will name such only as are likely to grow, viz.:—Portugal and common Laurel—the latter the best; of this I have seen a good bank in a most exposed situation, 1000 ft. up, on the face of a moor in the north of England. Other kinds comprise the Laurustinus (in shelter), Rhododendron, Aucuba (excellent), Berberis Aquifolium, B. Darwinii, Box, Cotoneaster microphylla, Lavender, Rosemary, and double Furze, the latter highly ornamental.

DECIDUOUS SHRUBS.—Common Azalea, Berberis vulgaris, Daphne Mezereum, Philadelphus coronarius or Mock Orange, Deutzia scabra, Ribes sanguineum (very hardy), Parsley-leaved Bramble, common Lilac, Spanish Broom, Weigela rosea, Sweet Brier, Scotch and other Roses of the hardest kind.

CLIMBERS.—Some of the foregoing, such as the Cotoneaster, may be trained as climbers if desirable, and the following may be added:—Ampelopsis hederacea (Virginian Creeper), A. Veitchii (for a warm wall), Clematis montana, C. Jackmanni and its varieties (very hardy), Ivies of sorts, Jasminum nudiflorum and officinale, Cratægus Pyracantha, Cotoneaster Simonsii (a rapid grower and free fruiter), Wistaria sinensis, and Honeysuckles.

The above selections are not extensive, but I have ventured to recommend nothing that I am not sure of, and it must not be forgotten that I am supposing cases where the shelter has first to be created; after this is accomplished, the variety might probably be increased, but hardly before that. A few years ago a gentleman with whom I am acquainted had his new mansion, situated on a high and bleak hill side, furnished by contract with the usual varied selection of trees and shrubs, many of them entirely unsuited, and the consequence was that before two years were over many species were dead, and others had made scarcely any growth; the place has since, therefore, had to be planted with commoner plants, but such as are likely to grow.

It now remains to say a few words about planting under the circumstances here contemplated. In the first place, nothing is so likely to promote a vigorous growth, or to sustain the vitality of plant life under adverse circumstances, as a good deep and well-drained soil. If the soil be not deep, then thick mulchings of any loose vegetable matter should be applied to the surface after the trees are planted, and for a year or two afterwards, till they have become fairly established. There is nothing so likely to promote the well-being of shrubs in any way as a good mulching. It retains the heat of the ground in a wonderful degree, and also prevents evaporation. The scathing dry winds of the spring months try newly-planted trees worse than anything else, as I have had occasion to observe very frequently, and their evil effects are felt ten times more if the soil be bare and hard, for then both branches and roots are literally starved with cold and drought. Another point is, in buying the stock to get what are called transplanted trees—that is, trees that have been moved perhaps two years previously. These are not nearly so likely to fail after planting as others are. Some nurserymen take great pains to transplant their stock periodically, while others do not trouble themselves to do so; but to the buyer it is a matter of much importance. The non-transplanted trees are generally the finest-looking and largest, never having received any check—a fact which frequently deceives the inexperienced, but they have proportionately few roots, and lifting them as they are usually lifted in a nursery simply half ruins them, and it is long before they recover the shock after planting; while transplanted trees experience little or no check at all. With the exception of Hollies, which should be planted in August, or in May or June, according to the locality, the general planting should be done in October or early in November, or it should

be deferred till March or April following. Unless in very favourable seasons mid-winter is the worst season in the whole year for such work, and especially so in cold districts. Care should be taken to have the plants put in the ground as soon as they arrive from the nursery, where they should remain till they are wanted. When warmth and shelter round the house and gardens are the objects, the hardier species—such as the Firs, Birch, Willow, Mountain Ash, and others—should occupy the background, chiefly at those points from which cold winds prevail, and thick planting should be the rule. Thinning can be effected afterwards, if necessary, but nursing for the first few years is of great importance, and thick planting is the best protection. J. S. W.

NEW PLANTS, &c.

Stapelia olivacea.—A South African species, having dingy greenish flowers barred with brown, each about the size of a florin. The erect four-angled stems are covered with short downy hairs. It succeeds under ordinary treatment; but it is not at all a showy plant.—"Botanical Magazine," t. 6212.

Saccolabium Hendersonianum.—This is a pretty little pink-flowered species, which has been known in this country for several years under the name of *S. Cruikshankii*. It has narrow, fleshy, glaucous leaves, about 6 in. in length, and erect spikes of pale rosy flowers, the lip consisting nearly entirely of a long, white, flattened spur, fully half-an-inch in length. It is a native of Borneo, and is not very showy.—"Botanical Magazine," t. 6222.

Alonsoa acutifolia.—A slender growing herb, 1 to 2 ft. in height, bearing opposite ovate leaves, coarsely serrate, and erect spikes of bright orange-scarlet flowers. It may be freely propagated from seeds or cuttings, and makes a very pretty decorative plant in pots, or for out-door decoration in the flower garden during the summer months.—"Gartenflora," t. 849.

Anthurium Saundersii.—A singular-looking climbing Arad, bearing elegant, bright, green, digitate leaves at intervals along its slender rhizomatous stem. The digitate segments of the leaf droop gracefully, and are 6 to 8 in. in length and about $\frac{1}{2}$ in. wide in the broadest parts. The spathe are small and green, the spadix being about $2\frac{1}{2}$ in. in length, of a greenish colour, tinted with rose at the base. Although not showy, it is of graceful habit, and might be useful as a climber on the back wall of a moist stove. It was sent to Kew from Mr. W. W. Saunders' collection, under the erroneous name of *A. coriaceum*.—"Botanical Magazine," t. 6218.

Epicisia erythrops.—A very pretty pale rosy-flowered Gesnerid, from New Granada, having broadly lanceolate or ovate leaves, 1 ft. or more in length, of a bright green colour above, and a dull reddish-purple tint beneath. It has been introduced by Messrs. Veitch & Sons, and flowered in their nursery at Chelsea in March, 1874. The pale rose-coloured flowers, borne in dense clusters Monolena-like at the base of the crimson leaf-stalks, render this plant a very ornamental one for stove culture.—"Botanical Magazine," t. 6219.

Talinum Arnotii, a South African plant, belonging to the Portulacaceæ, having a thick brown stem or root-stock; ovate, alternate leaves, and bright yellow quinque-partite flowers each, the size of a shilling, and borne solitary on slender pedicels from the axils of the leaves. This plant is likely to be of botanical interest only.—"Botanical Magazine," t. 6220.

Bouchea pseudogervaoi.—An annual Brazilian herb, with opposite Nettle-like leaves and slender terminal spikes of bright purple flowers having a conspicuous white eye and yellow anthers. It is a weed in many parts of Peru and South Brazil, inhabiting woods, waste places, and rubbish heaps, and belongs to the Verbenaceæ, being, indeed, very nearly related to the Verbenas. The plant was introduced by Messrs. Veitch & Sons, with whom it flowered in September, 1874.—"Botanical Magazine," t. 6221.

Felargonium oblongatum.—A pale-flowered species from the Cape of Good Hope, bearing large yellow flowers in terminal clusters, the anthers being borne on slender curved filaments and of a bright red colour. It is in cultivation in this country, and is likely to be of some service to hybridisers. The figure cited below is a most faithful portrait so far as the flowers are concerned, but no evidence is given of the characteristic thickened root-stocks, and the foliage is represented as contemporaneous with the flowers, whereas it is never or very rarely so produced by the plants we have seen in cultivation at Kew and elsewhere, and we find this character well shown in the "Botanical Magazine,"—"Revue Horticole," 1876, t. 91.

PEARS ON APPLE STOCKS.

Fruit growers are more than ever on the alert to discover any possible improvement in the raising and management of fruit trees. The selection of suitable stocks, according to the object in view, is, of course, of the first importance. Although the Pear will thrive, for a few years at least, on many of its more or less near allies, as the Hawthorn and Medlar, nurserymen rarely employ more than two kinds of stock—usually the common Pear and the Quince. Within the last few years double grafting has found some very strong advocates, notably Mr. Thos. Rivers, who says that an acre of double-grafted Jargonelle Pears would be a little fortune to a gardener. The stock in this case is the Quince, grafted with the Beurré d'Amanlis Pear, and this with the Jargonelle. Mr. Stole, the Director of the Pomological Institute of Proskau, writing in the "Monatschrift," for March, on this subject, again recommends grafting Pears on Apple stocks. The main advantage of this stock is early productiveness; and this is an important consideration to many planters. Mr. Stole states that Pear trees thus raised will bear good fruit the second season; and, although they are not very long-lived, they are exceedingly prolific for a number of years. The Apple stock is not advocated for permanent orchards, but it is said to be very advantageous and profitable to the growers for market, to whom a speedy return on the capital expended is of great moment. This plan finds practical application in some parts of Prussian Poland, where fruit is largely grown for the markets of Berlin, Posen, &c. At Czerventitz, near Posen, the writer saw last autumn considerable plantations of miniature Pear trees on Apple stocks, each tree laden with handsome fully developed fruit, and abundantly confirming the merits of the system for the purposes indicated. To ensure success, strong healthy stocks alone should be employed. No particular varieties are recommended, but we presume those commonly grown for market are intended, as the writer goes on to say that fine fruit of Beurré Diel, &c., weighing a pound each, will fetch from 1s. to 2s. each, even in Posen. But it must not be forgotten that Posen, although a degree north of London, possesses a much more favourable climate for ripening fruit than any part of England. Grapes ripen perfectly against reed screens or palings. Nevertheless, grafting Pears on Apple stocks may prove to be of practical value in this country. H.

The French Paradise Stock.—Thinking, during some recent discussion as to the merits of this stock, that experienced growers in America might be able to throw some light on the subject, we wrote to Mr. J. J. Thomas, a pomologist of long and deserved repute, author of a standard book on fruit culture, and pomological editor of the "Albany Cultivator," who obligingly replied as follows:—"The French Paradise Stock grows well on strong soils, with suitable pruning and cultivation. Neglected, and on light soils, it frequently falls after a lapse of several years. The oldest trees with which I am acquainted in western New York are on the grounds of Ellwanger & Barry, at Rochester. Trees which have been worked on it thirty years old still possess a fair degree of vigour, having stems 6 in. to 8 in. in diameter, and the trees are about 8 ft. high, with about the same extent of branches. Twelve-year-old trees are 5 ft. or 6 ft. high, and 4 in. or 5 in. in diameter. On my own grounds, which are a strong clay-loam, trees which have been planted twenty-five years are 7 in. in diameter at the base, and are about 10 ft. high, with 10 ft. spread of top. These have been sparingly pruned. In these remarks I carefully distinguish the true French Paradise, with its peculiar yellow wood and small fruit, with a mixture of sweet and bitter in its flavour. It will always afford me pleasure to furnish any information I may possess in relation to fruit culture in this country.—J. J. THOMAS.

Picking Over Apples.—There is much to be said both for and against picking over Apples. I would give little for the discretion of a person who would not touch his Apples from the time when they are gathered until they are used. To say that decayed fruit will not infect their neighbours is against both reason and experience; uninfected their neighbours is against both reason and experience; gathered and going through what is termed the "sweating" stage; let one decayed fruit remain, and it will be found that it will affect all around it. I have not been convinced of this by a solitary instance, but by thousands. The process is much more rapid at this stage (sweating) than afterwards, though at all times it is certain to take place, except, perhaps, in the case of a few very hard-skinned fruits. Handle fruit as little as possible at all times, and especially after the New Year; if it be wanted to keep, not a fruit should be "picked" up in the hand and placed in another part of the room, as is usually done, just to keep all tidy. Of course, this does not matter much in the case of cooking Apples.—JOHN TAYLOR.

NOTES OF THE WEEK.

— IN the old-fashioned flower garden at Wimbledon House there is a fine plant of *Cydonia japonica*, 60 ft. in circumference, and from 8 ft. to 10 ft. in height. Being now covered with bloom, it is, as might be expected, a very striking object.

— WE have just seen flowers of Mr. Geo. Smith's new double-flowered zonal Pelargonium, named Wonderful. It is a sport from the well-known variety called Vesuvius, and one which is well adapted for decorative purposes and for supplying cut flowers. Its colour is a brilliant scarlet, and its flowers are very durable.

— THE *Fritillaria*, called *F. meleagris* var. *Hector*, in Mr. Barr's collection, and now in bloom, is a very singular plant, not without beauty. It seems larger and stronger than the type, and is shining green outside, and spotted and netted with dull crimson within the large drooping bell. If a variety of the common Snake's-head, which is doubtful, it is a valuable one.

— DR. TRISTRAM, the Chancellor of the diocese of London, on Monday week granted the application by the Rev. H. Jones, rector of St. George's-in-the-East, for a faculty to convert a part of the churchyard into a flower garden, so that we may hope to see more London graveyards made beautiful. The planting of a few trees likely to live in London should take precedence of every other kind of gardening, however, in such places.

— IT is with satisfaction we notice that the beautiful varieties of *Auriculas* are becoming plentiful at our London flower shows in spring. There are surely no more lovely flowers, especially when grown as was the collection shown by that excellent cultivator, Mr. Douglas, at the Westminster Aquarium the other day. We trust that many amateurs will take up their culture, and that raisers will so strain their rules that we may have all the variety of lovely colour of which the plants are capable, as well as the particular modulations desired by the "Florists."

— MR. PERRY, in the Hale Farm Nurseries, dotted some hardy bulbs through the tufted carpets of the mossy Saxifrages last autumn. They were not planted so as to touch the earth, but simply plunged in the moist mossy tufts. All the bulbs rooted through the Saxifrage into the earth and flowered, and the effect has recently been very pretty. The carpets formed by the dwarfed mossy Saxifrages offer good positions for the growth of small bulbous and similar plants, and they do not hurt each other in the least.

— THE idea of the wild garden has been taken up with earnestness by many lovers of hardy flowers. A forester, writing to us this week, says:—"I am forming plantations of the Lily of the Valley, with which one of our outskirting woods is overrun. I have brought in three cartloads of it to plant alongside our drives. I planted three cartloads of Daffodils two months ago: they are now in blossom, and look effective already." Our woodlands thus treated will, we believe, in good time afford more real beauty than the prim flower-gardens of the present day.

— FROM Aldborough Rectory gardens—one of the old homes of the rarer hardy flowers—the Rev. Mr. Nelson sends us blooms of *Polyanthus Golden Prince*, which he describes as just now a blaze of colour in the garden. It is a robust and beautiful variety, of a rich golden colour throughout. Although called a *Polyanthus*, it has the broad showy flowers of the stoutest forms of the *Primrose*. From the same garden we also have *Primula Nelsonii*, a white Alpine *Primrose*, of the origin of which we know nothing, but it is no doubt a white form of *P. viscosa*.

— THE Rose has been so long the subject of ill-treatment at flower shows, arranged in the stiffest possible manner in oblong boxes, that it is pleasing to notice a slight change for the better. The Roses shown at the Westminster Aquarium show the other day in round baskets, were very attractive. Messrs. Standish had some in baskets, with a nest of Rose-leaves round each small group of flowers. Mr. Willis' way of placing Roses singly or in groups, in rich flakes of *Lycopodium*, is also good. We shall no doubt soon see the Rose, with all its beauty of foliage and natural grace, at our flower shows, as well as in all its glory of colour. It, however, is but one of many subjects that, as yet, are not seen to advantage at our flower shows.

— IT is with great pleasure we notice that the beautifully laced *Polyanthuses* are beginning to be seen at our flower shows once more, and we hope they may find a home again in many gardens. There seems some monotony in them at present as regards colour, and it is to be hoped new raisers will not be so guided by old rules, that the variety so desirable in such plants may not be gained. A hardy race of well marked and beautiful forms is what is wanted for our gardens generally. Raisers would do well to consider the names they give these modest flowers. One was named "Consternation!" This reminds us of a nursery catalogue in which a modest but free-blooming Alpine flower is described as a "tremendous bloomer."

A Well-bloomed *Pyrostegia ignea*.—At a recent fortnightly meeting of the Central Horticultural Society of France, a branch of the beautiful and but little known *Bignoniaceae* plant, described by Presl in his "Symbola Botanica" under the name of *Pyrostegia ignea*, and known to other botanists as *Tecoma venusta*, was exhibited by Madame E. Léon, from Sainte Croix, near Bayonne, Basses-Pyrénées, profusely covered with flowers, which excited much interest, as the plant is but a shy bloomer and of difficult culture in the neighbourhood of Paris. Madame Léon was requested to inform the society whether the abundant bloom on her plant was due merely to the warmer climate where she lived, or to any special system of culture adopted by her. A special certificate of merit was awarded it.—W. E. G.

Gardenia Flowers all the Year Round.—Though the natural flowering season of *Gardenia florida* is early summer, yet it blossoms during winter and early spring; indeed, the same plant produces flowers in succession for a long period. One cultivator, who grows it in quantity (old bushes, seldom re-potted), on the back shelves of his warmest Pine stove, tells us that he is hardly ever without flowers all the year round. At all events, by having a few bushes and moving them into the hottest division as required, a succession of flowers may be had for a long period. The *Gardenia* is so strongly scented that one flower is usually enough at a time for a room. It forms a handsome shrub, which should not be over-potted, and, during the growing season it should be well exposed to the light, but thinly shaded from bright sunshine. Heat and moisture it delights in while in active growth, and at all times it will perhaps bear with advantage as high a temperature as any stove plant. Some recommend cutting back the shoots freely after flowering; but, except so far as keeping the plant in shape, the practice is not essential. The great point is to get a free growth and keep the plant free from insects—bug and scale—which are exceedingly partial to it.—W. S. J.

Flower Beds.—What is your opinion as to the propriety of planting an oblong bed as follows:—Centre block, *Coleus Verschaffeltii* splendens, edged with two rows of *Crystal Palace Gem Pelargonium*; or shall I use *Golden Feather* instead of *Pelargonium*?—H. M. [You had better use the *Pelargonium Palace Gem* in union with your improved *Coleus*, and if you were then to edge the bed with *Blue Lobelia*—say two rows of *L. pumila grandiflora*, or *Blue Stone*, the effect would be much improved. One of the prettiest round beds we saw last season was planted thus—*Central mass, Coleus*, then a ring of *Centaurea ragulina*, then a row of *Iresine Lindenii*, followed by the *Golden-leaved Pelargonium Crystal Palace Gem* and *Blue Lobelia*.—B.]

Cape Heaths at Home.—As regards vegetation, I believe Nature is neither so unyielding nor inflexible as many insist, but is, to a certain extent, governed by circumstances. That Nature often deviates from accustomed ways, and seems none the worse for the change, is obvious to all intelligent observers. In corroboration of my assertion, I will cite but one instance, which came under my notice in South Africa, namely the *Erica*, which is an interesting genus, always considered so difficult to manage in cultivation. Of all the plants which come under a gardener's care, *Cape Heaths* require, probably, a higher order of floricultural skill than most other plants do to ensure success. At the Cape of Good Hope, *Erica imperialis*, *E. pelucida*, *E. grandiflora*, *E. viridiflora*, *E. vestita alba*, *E. mirabilis*, *E. princeps*, *E. blanda*, and many others, I saw springing from slight cracks and openings in the rocks, and growing amazingly, with apparently little or no soil to support them, and where the sun's rays literally blazed upon them. The same kinds, with numbers of other species, were equally happy and vigorous on the mountain-sides, beneath shady, broad-leaved forest trees; near the sea-beach, in the snow-white sand, and in boggy hollows. With such a variety of soils and conditions, they flourished, as if to show the different ways Dame Nature had of doing things.—W. T. HARTING.

THE GARDENER'S SOLILOQUY OVER THE SEED CATALOGUES.

To sow? or not to sow?—that is the question:
Whether 'tis nobler in the mind to suffer
The greatest torment of a gardener's life
In poring yearly through "fat catalogues,"
Or to take means by popping them, when sent,
In the waste basket—to be looked to
No more; and by doing so, to say we end
The thirst for new and "special novelties";
That flesh is heir to. "Tis a consummation
Devoutly to be wished. To grow?—to sow?
To grow?—perchance to cram our beds and borders
With useless rubbish. Aye, there's the rub!

W. TILLEY.

THE INDOOR GARDEN.

A NEW HALF-HARDY BULB.

(SYRINGODEA PULCHELLA).

This is a dwarf slender-habited little plant from Southern Africa, almost *Crocus*-like in general contour, but more nearly allied to the *Ixias* and the *Trichonemas*, both strikingly handsome genera now too seldom met with in gardens. It was discovered by Mr. H. Bolus in plains among the Sneeuwberg mountains at an elevation of about 4600 ft. above the sea, where it flowers in April; bulbs collected by him and sent to Kew flowered in September 1873. Our illustration represents the plant as figured in the "Botanical Magazine," t. 6072, about half the natural size, the whole plant, flowers and all, rarely exceeding 4 in. in height. The bulbs are about the size of small Hazel Nuts, and of nearly the same colour, the slender sub-cylindrical leaves being almost thread-like, and of a deep green hue. The flowers are solitary, and somewhat *Crocus*-like in form and colour, the tube being very slender and

Syringodea pulchella.

nearly 3 in. in length. The perianth segments are open or gently incurved, and of a soft lilac colour streaked with deep purple behind. The three anthers are closely adpressed, and of a golden yellow hue, the apex of the long and slender style being tri-lobed, and fringed with short hairs. It is a most elegant and attractive little plant, and one which, together with its allies, we should like to see more abundant. B.

CISSUS DISCOLOR FESTOONED.

It is not too much to say that this is one of the most singularly beautiful of stove climbers. When grown in a hot stove, where it ought to be, the leaves acquire that gorgeous lustre and colour which give the plant its splendid appearance; and it is only when it is allowed to scramble in festoons about the roof of a house, drooping its long tapering shoots here and there, that it is seen in its true character. To train it on a balloon-shaped trellis, as it often is for exhibition purposes, is about the worst way of growing it that could be conceived. The plant must have a high temperature and generous treatment, as it will grow 20 ft. or more during the summer months, and produce leaves splendid both in size and colour, and such as can be produced in no other way. We once grew it in this way in a warm Orchid house—running it round the house in festoons, and up and down the columns, never restricting it in any way, and it

was a spectacle worth going miles to see. It is seldom that this *Cissus* is grown in this way or grown well, and though the leaves are always beautiful, it is only when it is growing fast and draped with plenty of young shoots and leaves, that a true idea of its beauty can be formed. It strikes freely from cuttings made from the points of the young growing shoots, and inserted in sand under a bell-glass, and plunged in a bottom-heat of about 90°. Young plants succeed best. We used to strike them annually in February, for the purpose referred to, and always had good plants. As soon as the cuttings were struck they were potted off in 4-in. or 5-in. pots, and again plunged in bottom-heat in a hot pit, and when the roots reached the sides of the pot they were shifted, for the second and last time, into 10-in. pots; the compost should be loam and peat in equal quantities, about one quarter well-rotted cow manure, and plenty of sand if the loam be heavy. After this they were put in the same pit again till established, and then removed to the Orchid-house about the middle or end of April, when the temperature of the house had attained to about the summer figure. A plant was set to each iron column, up to the top of which they ran directly, and then they were led round the house on both sides of the path with string, which is handier than wire for festooning. We are preparing plants in this way now for a similar purpose. It is too late now to put in cuttings, but young plants are cheap, and half-a-dozen are sufficient for a long house if treated as here directed. The only enemy almost the plant has is the mealy bug, but a little attention with the brush will keep it down if the plants be kept growing fast, as they then run away from it. Frequent applications of liquid manure will also be serviceable in promoting a quick and vigorous growth. J. S. W.

BRYOPHYLLUM CALYGINUM.

This is a singularly interesting plant, both as regards foliage and flowers. When in bloom it presents successively two distinct aspects; first, when the calyx develops itself—membranous, inflated, smooth as silk, cylindrical, round at either end, of a pea-green colour streaked with red, increasing in size until it becomes 1½ in. in length; and afterwards, when the corolla-tube, which is five-cleft and of a dull red colour, breaks through and protrudes half-an-inch beyond the toothed limb of the calyx. In a neighbouring greenhouse, a plant of *Bryophyllum*, three years old, from the leaf-bud, is now producing over 300 flowers—if I may call the oblong, inflated calyces flowers, for, as yet, few have revealed the corolla. The blooming-stalks are about 3 ft. in height. The flowers, borne upon slight pedicels, droop directly downwards, and are swayed by every breath of air like so many suspended Chinese lanterns. In panicles, 300 or more of these form a singular display, and one that is, perhaps, worth waiting three years for, if one is not already over-familiar with the plant. But there are other characteristics about *Bryophyllum* that render it desirable, foremost among which may be mentioned its endless powers of reproduction. Years ago I was told, when first I procured a leaf, that it was necessary to suspend it by a thread in an airy warm place, so that nothing should touch it, and that in three weeks young plants, furnished with root, stem, and leaves, would develop at the end of every nerve or between the crenatures. I followed the directions, and the promise was fulfilled; but had it been placed upon the mantel-shelf, or upon earth, the same result would have followed. Indeed, I have found plants 6 in. high in the garden which had, through the summer, grown from fallen leaves. It is not true, however, that a bud grows from every junction of two scollops; a parent leaf does not seem able to produce or support more than two or three plantlets, and these appear only when it begins to wither. Le Maout and Decaisne say that "these buds, which spontaneously fall off and root in the earth may be likened to embryos that do not need to be fertilised before developing; and the leaf may be regarded as an open carpel on which the seeds have been developed by nutritive action alone." But, in my experience, the buds do not drop off, but, on the contrary, if I remember rightly, are very persistent. After the plantlets have attained 1 in. in height, it is best to cut them out, leaving a portion of the parent leaf,

which will continue to support them until the small roots have taken hold of the soil in which they are planted. The compound leaves are unequally pinnate, with, for the most part, five leaflets to a main petiole. They are thick, opposite, elliptical, the terminal leaflet larger than the rest, and ovately elliptical, doubly crenate, dark green, fresh-looking and vigorous. The growth is exceedingly rapid, and the young plant thickly foliated, highly symmetrical, and beautiful in every way. As it grows old, however, or prepares to bloom, the leading stalk or stalks which grow as straight and as precisely graduated as a Bamboo cane, lose their foliage. If cut down they will start, however, with all the beauty and vigour of young plants. They may be treated the same as any other Crassulaceous plants, and flourish alike in the sitting-room, greenhouse, or border.

E. S. CARMAN.

River Edge, Bergen Co., N.J.

NEW DOUBLE POINSETTIA.

THIS, which you have so well represented at p. 288, seems likely to rank highly among winter flowering plants, for if it only turns out to be half as grand an acquisition as it is said to be, and is found to be as easily cultivated as the old single kind, it will undoubtedly soon become a popular plant. The fault of the Poinsettia is its rather lanky habit, which necessitates special culture in order to have it of a size and shape suitable for ordinary purposes. One great bush or thicket of the plant in a house where there was plenty of room, would doubtless be a splendid object: but for general decorative purposes it has to be grown in pots of various sizes, and to have it of convenient size its growth has to be restricted. It strikes very freely from cuttings. The usual way of providing a stock of plants for winter is to start the old stumps, which are usually kept rather dry and cool in a greenhouse or pit till June or July, in a stove,inery, or other place where a temperature of from 65° to 85° can be afforded them; they soon break, and as soon as the shoots are a few inches long, they are taken off, but clean at a joint in the usual way, and inserted singly in small pots, or, what is better, in the pots in which they are to flower, using a rich compost of leaf-mould and good turfy loam, or peat and loam, with a sprinkling of sand; but taking care to make a hole with the finger where the cutting is to be inserted, and to fill it up with silver sand, in which, of course, the cutting first roots. This plan saves the trouble of potting off, and the plant is not checked in growth. When struck singly in pots they need to be shifted on afterwards, putting one, two, or three plants in a pot just as desired. In dealing with the old *P. pulcherrima* at one time, when we used to get batches of it speedily, and with as little trouble as possible, the cuttings were put in a few inches apart round the side of a 6-in. or 7-in. pot, and one in the middle. In this way they were struck, and afterwards pushed on rapidly till they flowered. One object was to have a bushy plant, and the cuttings were put in in August. Of course the old variety produces but thin or single flowers, and a thicket of shoots was needed to get a good display; but with the new, double, large-headed one, single plants will no doubt look well, and it will be advisable to crowd the cuttings. To strike it successfully it requires a close and moist stove temperature and a bottom-heat of 85°, or thereabouts. General culture consists in liberal watering and generous treatment, in order to get stout shoots and good heads of bloom.

J. S.

THYRSACANTHUS RUTILANS.

THIS is an excellent winter-flowering plant of easy culture. Its roots grow up singly and perfectly straight to a height of 2½ ft. or 3 ft., and long racemes of bright crimson flowers are produced from their summits, and droop gracefully down to the surface of the pot. There are few or no plants that have the peculiarly graceful weeping habit of the *Thyrsacanthus*, a circumstance which renders it so useful for certain positions—as, for example, on a pedestal, around which the flowers hang like a crimson drapery. I ought to state that the size just recorded relates to the annual growth, for the plant attains to a height of 5 ft. or 6 ft. if not cut down; but vigorous young plants, cut down when done flowering, or propagated from cuttings, make the most useful specimens. Perhaps the best way is

to grow plants from cuttings annually, as follows:—After flowering a cluster of young shoots is always produced at the top of the old ones. These should be taken off, cut below the third joint, and struck in sand in a moist close temperature on bottom-heat, like the *Poinsettia*. When fairly rooted and slightly hardened off by being lifted out of the plunging material, they should be potted in 6-in. and 8-in. pots, two or three plants in a pot, in order to make a bush, and in a rich compost of leaf-mould, tan, rotten manure, and sand. They will require no further shifting, and they need no staking. From the time they are potted till they come into flower they must have a genial stove temperature, and be grown on rapidly, taking care that they are not pinched for want of water or checked by cold, evils which cause the lower leaves to fall off. By November, if all has gone well, they will be throwing out flowers, with long thread-like stems, which generally push a foot or eighteen inches before the first flowers expand, while the extremity of the runners usually fall below the level of the pot; consequently the plants must be lifted well up and placed upon an inverted pot, or something else, so as to give the flowers light and air. The plants will continue to throw up flowers throughout the winter, but it is well to have a few plants retarded in an intermediate house to insure a succession. Cuttings may be put from February to May, but after April it is better to trust to cut down plants shaken out and re-potted and started in bottom-heat. CHEF.

PHALÆNOPSIS INTERMEDIA BRYMERIANA.

I HAVE just seen this novelty, kindly furnished by Mr. Brymer, of Ilington House, Dorchester, and a most beautiful variety it is, bearing from twenty-five to thirty flowers, rather closely arranged on a dark purplish-coloured spike. The flowers are those of the typical *P. intermedia* of Lindl. (see Lem. Jard. Fl., t. 44) in size and shape, but very different in colour from either those of the type or *P. Portei* now in bloom in the Londesborough collection. The flushing of soft lilac at the bases of the sepals and petals reminds one of the figure of *P. Portei* in Warner's "Select Orchids," but here in addition to the soft spreading wash of lilac, we have distinct indications of the dotting which belongs to the typical plant, and as shown in the late Dr. Lindley's own sketch now in the Herbarium at Kew. This *P. intermedia* is a singular plant, for although we have only six or eight examples of it in cultivation, scarcely two are alike. Messrs. Veitch have a form very near the type of *P. intermedia* as figured by Lindley, but in this case the petals are pure white, and the lip shades into white at its bicirrhose apex, and the *P. Portei* in the Londesborough collection has not the flushing of rosy lilac on the sepals and petals as in the specimen figured from Mr. Robert Warner's collection. The new *P. Brymeriana* is, however, abundantly distinct as a variety from all others which I have yet seen, and to my mind is by far the most beautiful. Its sepals and petals are white—pure crystalline white—delicately flushed with lilac at the base, and also furnished with evidence of profuse dotting, the lateral sepals being distinctly dotted with brown just behind the lip, viewing the flower from the front. The lip is very beautiful, the lateral lobes being of a bright amethystine-purple at the rounded extremities, delicately veined with deeper purple, while their narrowed and thickened bases are of ivory-like whiteness, and having the characteristic brownish streaks and dots. The crest resembles that of *P. amabilis* in being white suffused with yellow, and dotted with brown, but it is smaller, and the basal lobes are not quite so distinct. The central lobe of the lip is yellow at the extreme base near the crest, and profusely dotted with red; then the yellow becomes suffused with bright amethyst purple, forming a rather bright maroon tint, which shades into bright amethyst at the bicirrhose apex, even the short tendrils being amethystine. A dark purple line runs down the middle of the central lobe of the lip, and as this approaches the bicirrhose apex, it forms a short ridge of about two lines in length, and easily seen when the flower is viewed laterally. It is very difficult to describe the brilliant colouring of the lip, but it seems to have more blue in it than any other of the forms of *P. intermedia*, and this gives an amethystine or stained-glass-like appearance to it, similar to that of the best and brightest forms of *P. Luddemanniana*, and it is this brilliancy which adds so much to the distinctness and attractiveness of the plant as a distinct variety. The column is of a bright rosy lilac colour. Independent altogether of the glowing colours of the lip, as contrasted with the more chaste crystalline lilac-flushed sepals and petals, the latter are delicately rounded and of great substance; hence the plant lasts a long time in beauty.

F. W. B.

Ivy in Houses.—Some time ago one of your correspondents inquired as to the healthiness of Ivy in houses. It is often grown in rooms in Norway and, I believe, in Sweden for its beauty, and I have seen it trained over a window and along the walls in graceful festoons. It cannot, therefore, be unhealthy.—P.

THE KITCHEN GARDEN.

SCARLET RUNNER BEANS IN TRENCHES.

For some time after its introduction into this country, the Scarlet Runner was merely prized for the beauty of its brilliant blossoms, and had not its merits as a vegetable become so fully recognised, it would doubtless have been largely employed as a decorative plant in pleasure grounds, from which it is now generally banished. Nevertheless, for climbing round and covering old tree stumps in shrubby borders, few climbing plants are more suitable or effective. Considered, however, merely as a vegetable, it deservedly holds a high position, as, owing to its easy culture and enormous yielding properties, and being more than most occupants of the kitchen garden uninfluenced by seasons or disease, a large amount of produce may be obtained from a small space of ground.

There is one point connected with its general culture, however, which has somehow escaped attention, and that is the want of a system of sowing to ensure a proper succession of tender Beans during the season. In the generality of gardens, one particular spot is chosen for Scarlet Runners—often some boundary line where they are intended to shut out some unsightly object. Here the one annual sowing is made, and if the season happen to be hot and dry, the chances are that just when their produce is most needed, they run short. To ensure good produce, a fair supply of nutriment when the plants are in full bearing should be the first consideration. Runner Beans, when in full growth, make heavy demands upon the soil, and if not complied with, an attack of red spider and consequent deterioration in quality are the result. To ensure perfect success, some pains should be taken in the preparation of the soil; and the most uniformly satisfactory system which I have ever employed is sowing in trenches, that is to say, slightly below the level of the surrounding ground, a plan which ensures their being thoroughly watered in dry weather. The ground should be marked out with a line to the length required; the soil should then be taken out two spits in width and about the same in depth, cutting down one side quite straight and level, and throwing the soil out on the opposite side. This should be done some time before the Beans are planted, in order to allow the soil thrown out to become well sweetened. At sowing time, having previously placed good strong sticks close at hand, a layer of manure should be placed in the bottom of the trench; a lad should then take the sticks and place their ends firmly upon the bottom, setting them upright against the even side of the trench; a man should then fill in with the soil already mentioned, mixing with it some manure as the work proceeds, and treading the sticks firmly in, in order to make all secure. In this manner the labour of cutting sticks will be saved, and they will have a firmer hold of the ground than they would have if merely inserted in the ordinary way—no small advantage, as in exposed situations they are liable to get displaced in rough windy weather. Where one pair of hands only are employed, enough soil must be drawn to the sticks as they are placed in position to keep them upright until the trench can be filled up. If, as I have mentioned, the trench be not quite filled, and if, moreover, it be mulched with manure or litter of some kind, the labour of watering will be much reduced, the whole amount given going direct to the root. The evil regarding watering outdoor crops grown upon the level without mulching is that the water does not penetrate readily where it is most needed; the surrounding soil being lower than that actually occupied by the roots, the water runs off without benefiting the plants. To many, this method of growing Runner Beans may appear to involve a greater amount of labour than is necessary; I write, however, for small cultivators—those principally who are obliged to make the most of a limited area. Market gardeners, of course, who grow Beans in large quantities are naturally obliged to get through their work in a somewhat quicker way, and could not well be troubled with sticking and other details of that kind. I am sure, however, that anyone who will make a trial of the plan just recorded, and will compare the results with those obtained in the ordinary way, will never begrudge the extra time and labour bestowed. I should not recommend Runner

Beans to be sown before the first week in May, as if up before the latter end of that month protection must be afforded them, and many would not care to incur that trouble. A second sowing should be made towards the end of the month, and then again about the middle of June. These three sowings will ensure a good succession of tender juicy Beans, care being taken to keep them well gathered, as if the haulm remain heavily loaded for a few days only, its growth will be stopped and the yield much diminished. There is no advantage in allowing the haulm to run to a great height; therefore top it at 5 ft. from the ground, so as to have the Beans lower down, where they can be seen and easily gathered. So much ground will not then be over-shadowed and made useless. Runner Beans are excellent preserved in brine and kept for winter use. I have often wondered that they are not more extensively used in that way than they are, for, when properly done, they may be had good during nine months out of the twelve. I have eaten in the months of January and February Runner Beans as juicy and full of flavour as when freshly gathered in the growing season.

In order to preserve Runner Beans good and fresh for winter use they should be cut in the ordinary manner as for boiling, well dredged with salt and placed in a glazed earthenware jar. It is not necessary to fill the jar at once, but each time Beans are put in they should be covered with a layer of salt, and the jar should be covered. In this manner they make their own brine. Only young tender Beans should be used, and upon using care in this respect depends the perfect success of the process; all old and tough Beans should be rejected, for, if any containing seeds be employed, the brine becomes tinged and the Beans when boiled discoloured. Beans thus preserved should be soaked in cold water at least twelve hours before cooking, in order to draw out the salt. I have lately cooked some which had been two years in pickle, and found them in all respects perfectly good.

J. CORNHILL.

Bylect.

Self-covered Seeds.—Mr. F. Darwin read before the last meeting of the Linnean Society a paper on the "Twisting of the Awn in Stipa and other Plants," the effect of which is to force the seed into the ground; the upper feathery end of the awn being relatively fixed, the seed worms its way into the soil. Mr. F. Darwin, finding that the seeds so buried did not germinate so well as those which were simply placed on, or just beneath the surface of the soil, suggested that the burial of the seed was intended as a protection against seed-eating birds.

Potatoes by Express.—At a late meeting of the Royal Horticultural Society, Messrs Hooper, of Covent Garden, exhibited a dish of the Potato Alpha, the result of a simple mode of forcing adopted by Mr. Barker, of Littlehampton. The sets were planted on January 13 in large pots, which were placed in a greenhouse pit facing south, from which frost was excluded by a single flow and return pipe. On March 7 the crop was lifted, and a portion sent for exhibition. The tubers were of good size, the colour delicately white, with a very faint tinge of rose about the eye.

House Sewage (see p. 307).—House sewage in the garden, if used with moderation, causes both fruit trees and vegetables to grow more luxuriantly, especially in dry summers, than they otherwise would do. If the sewage be strong it is best to dilute it with one half water when applying it to Strawberries, Currants, Gooseberries, and standard fruit trees. The best time to use it is after the fruit is set and swelling, and in the case of Strawberries it should be discontinued some time before the fruit begins to colour, for fear of deteriorating its flavour. It may be applied to vegetables without dilution after showery or rainy weather; it is particularly suitable for all the Brassica tribe, and for Celery. I have never tried it for evergreen shrubs or for coniferous trees, but if used in dry summers in a diluted state I should think it would be the means of making them grow more vigorously.—W. TILLEY, *Welbeck*.

Celery and Celery Trenches.—The produce of the first sowing will be up some time ago, and care should be taken to keep the young plants from damping off. I generally sift a little good soil or old rotten manure, and distribute it with the hand amongst the young plants, which strike fresh roots into it. Never allow them to get dry, if possible, and when the plants are ready for the nursery bed, get them pricked out as soon as possible. I water them every day, and when the plants are established I apply diluted nitrate of soda, but with care. I make my trenches 10 in. deep, and from 15 in. to

18 in. thick, and 5½ ft. from row to row in March; forming the trenches late in the season is a mistake. I keep the manure as near the top as possible; but too much manure will produce coarse produce. My Celery never runs to seed nor becomes hollow, but it will make a joint or two, and that is considered the best part of the Celery. I generally plant from the end of May to the second week in June; when I lift the plants from the nursery bed, I dip them in a tub of water; by this plan I get the roots straight, and they go better through the manure. But of course this is immaterial, as the plant will make fresh roots. In THE GARDEN of January 1, a correspondent says:—"Celery, to be of the highest quality, white, crisp, and sweet, should be all blanched at once," I say no. Earth-up a little at a time, just as the heart grows up, for, when Celery has done growing, there should be no blanching.—JAMES RAMSAY, *Retford*.

THE LIBRARY.

SCIENCE PRIMERS.*

A SCHOOL Primer, written by a President of the Royal Society, is perhaps without previous example. Students may now begin the reading of botany with the aid of a grammar stamped with the highest authority, and may therefore reasonably expect to take their first lessons from a source uncontaminated with the ignorance, errors, and loose expositions which have often infected such books in this as well as in other sciences. But after perusing it, we cannot exempt the present work from a few serious slips, and several cases of careless composition. In order to make it safe for placing in the hands of beginners, the more important mistakes and misprints ought to be corrected; and it is to be hoped that a page of errata will be promptly added. It is surely not a sufficient definition of a Catkin, that it "is a spike that falls away after flowering" (page 46); nothing is said about the flowers being unisexual. Again, it is not customary, though inexperienced observers readily fall into the mistake, to regard the Rose as having a superior perianth; and it is at least questionable whether pappus in Compositæ is itself the calyx, or even the representative of it. On page 108, we find the Buckthorn classed in the Order Celastrineæ, the Laurastinus in the Order Cornaceæ; and on page 110, the Order Retulaceæ is placed amongst the Monocotyledons—all blunders which are not only quite unaccountable, but perilous to the success of the book, and highly dangerous to candidates for examination. The lustrous hue and glossy appearance of leaves, in most cases, is explained on page 7, and again in nearly the same terms on page 49; such a needless repetition suggests want of care in preparation. The lettering of the parts of the figure on page 26 is omitted, leaving the student in doubt and bewilderment; and on page 72 the letters a and b of the figure are transposed so as to mislead; and, again, the figure of the Fig on page 82 is not magnified like the subjoined figures of the male and female flowers, although both are equally stated to be much enlarged. On page 38 we are told that the Elm increases only by terminal buds; while we cannot agree with the author in this statement, yet we perfectly appreciate and join in the recommendation of the study of the modes of branching of trees as being one full of interest, as well to the botanist as to the artist. "Leafless branches of the common English trees, suspended against a wall, are capital studies for pupils, and reveal characters that escape the observation of teachers whose attention has not been called to them" (page 40). The section on the fruit is concisely and clearly set forth, without the unnecessary complexity and fulness of nomenclature which encumber most, even elementary, manuals; also that on Conifers and Cycads is very satisfactorily given. The book consists of about 120 small octavo pages printed in clear open type, and is illustrated by sixty-eight woodcuts, many of which we remember as having done service in Oliver's "Lessons." At the end of the preface, the pupil is told that, after mastering the contents of the Primer, he may proceed to the use of Professor Oliver's "Lessons in Elementary Botany," which goes over the same ground in more detail. For our part, we see no reason why pupils who intend to proceed so far should not at once begin with Professor Oliver's volume.

Anacasia grandiflora.—A magnificent East Indian plant, also known under the appellation of *Acacia grandiflora*. It is a miniature of *Albizia Julibrissin*. It is extremely prolific, and the lightness and elegance of the flowers are quite out of the common. The foliage, too, is very beautiful, and it is strongly recommended to every one who has a hothouse or even a pretty warm greenhouse.—*Revue Horticole*.*

THE FLOWER GARDEN.

HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

The bright and warm days at the end of last week induced many blooms to open, but did little to change the backward character of the spring. The snowy-looking dots of the unopened flowers of the Bloodroot (*Sanguinaria canadensis*) appeared during the week, and where plentiful afforded a distinct and pretty effect. The best use for the plant is as a subject for naturalisation on the margins of shrubberies or under the branches of deciduous trees on the lawn, where, when its evanescent floral effects vanish, the blank spaces it leaves when it dies down are not conspicuous. There is also little danger of its being destroyed from digging and planting in such positions. The Snake's-head (*Fritillaria meleagris*), finest of its race, has also come into flower abundantly during the week. It has very high merit indeed, inasmuch as it is a fitting ornament for borders, bulb-beds, the margins of shrubberies, or naturalisation in grassy places. Some of the varieties are beautifully marked and shaded, so that they please on the closest inspection, while their distant effect growing among the early Grass is charming. The Crimean Iris (*I. pumila*) has opened its large and richly-hued flowers during the week on the coldest soils round London; it is a very hardy and a very precious plant, and some of its varieties are more beautiful than the type, like very large Orchid blossoms on very dwarf stems. Quite distinct from it is the diminutive Persian Iris (*I. persica*)

The Persian Iris.

with its singular and delicate hues and grateful odour. This is sometimes supposed to be a tender species, but in the Hale Farm Nurseries, where the soil is rather heavy, it is quite hardy, and flowers freely. There is no more interesting rock plant or choice border flower. The winter-flowering *Iris stylosa*, which Mr. Ellacombe sent us in mid-winter, is this year flowering round London now, and a very lovely spring flower it is. The new Tulipa Greigi flowered during the week in Ware's Nurseries, and a splendid flower it bears, orange-crimson with marbled leaves. The graceful *Epimedium*, which seldom look happy except in the milder sea-shore or hill districts, show their blossoms half-hidden among the spare foliage which they bear in London gardens; the Rush Daffodil (*Narcissus juncifolius*) is now in flower; it varies a good deal. The beauty of the earlier *Scillas* has past away; they are replaced by the faint blue Italian *Scilla* (*S. italica*). The old *Phlox verna*, once very popular in gardens, and worthy to be always so from its neat tufted habit, is beginning to show its rosy bloom. The fairest among the white flowers of the week is the White Buttercup (*Ranunculus amplexicaulis*), and among the blue the Apennine *Anemone* (*A. apennina*), which, like many other flowers, is much later than usual. The blue *Gromwell* (*Lithospermum prostratum*) begins to show its Gentian-blue blossoms, and the spring *Orobus*, some time open, is gradually showing more blossoms on its graceful tufts. *Dentaria digitata* is in full bloom, a slender plant with a stock-like bloom, admirably suited for quiet moist nooks, in half shady places and among shrubs. In the Stock Order we have also among the smaller plants in flower during the week the neat Mountain *Alyssum* (*A. montanum*), and the pretty white *Cardamine trifoliata*. Among the older Tulips there are *T. Oculis solis* or *præcox*, and the Wood Tulip (*T. sylvestris*) and its varieties. The seldom seen and beautiful *Pulmonaria virginica* is slowly expanding its purplish buds, and the

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

THE FRUIT GARDEN.

WALL TREE PROTECTIONS.

THE early season at which our choice wall fruits naturally come into flower renders the protection of their blossoms from injury by frost an important point in their cultivation. The present season has been well calculated to prove the relative value of the various kinds of wall tree protections in general use, as upon several occasions since the earliest blossoms of Apricots and Peaches expanded, the thermometer has denoted from 10° to 12° of frost, an amount which any one conversant with plant culture must know is sufficient to penetrate a well-glazed house, and greatly affect the inmates, even if they are far removed from the glass, unless artificial heat is applied. Under such circumstances it would require a considerable stretch of the imagination to suppose that any kind of coping could alone ensure protection sufficient to guarantee the safety of the crop. Yet we often see it stated that certain widths of projecting glass or other movable coping are sufficient protection against any amount of frost; but in what way copings retain heat better than a close-glazed roof I am at a loss to discover, and fear that those who rest their hopes of a crop on coping alone will have little use for the fruit-basket, *i.e.*, if their trees, when in full bloom, be exposed for several hours to a temperature of 20° Fah. On March 19 I saw such hardy foliage as that of the Christmas Rose lying prostrate on a well-sheltered border, under a projecting roof wider than those often employed for fruit tree protection. I have no wish to undervalue the protection afforded by copings in connection with a really efficient covering in the shape of blinds, fish-nets, or other contrivances of that kind, but I do think that the true value of a form of protection that can only end in failure, except on occasions when no protection is required, deserves to be pointed out. My own idea is, that the wall itself is the best protector, and that the closer the young bearing wood is trained to the brickwork the better. Copings and movable blinds are serviceable for keeping off storms of snow and hail, and also for mitigating extremes of temperature; they should therefore be used judiciously day and night, for, when thoroughly dry, several degrees of frost are required to destroy the blossom; whereas when wet a slight amount of frost is sufficient to complete its destruction. Something may also be said as regards the aspect of walls for trees, and the advisability of having a portion of both Peach and Apricot trees on other aspects besides a full south one. With us Apricots do well on a west aspect, which not only prolongs the season of ripening but also retards their flowering; those on south aspects being in full bloom during the severest frosts, while those on a west aspect are only just commencing to expand. It should also be borne in mind that west aspects receive the greatest benefit from the sun's rays late in the evening, and that a greater amount of latent heat is given out during the night, and that after a frost the sun's rays do not shine on the trees until the middle of the day, so that west aspects are not subject to such violent transitions as south ones—transitions which are even more destructive than severe frost. When movable blinds are employed, they should not be drawn up immediately after the frost disappears, but should be employed to mitigate the sun's rays until the day is well advanced. By careful attention to these apparently trifling matters, a crop will not only be secured, but the health of the trees will be ensured. J. GROOM.

Hemlock.

PROGRESS IN FRUIT CULTURE.

OUR young contemporary, the "Nord Est," a horticultural monthly which appears at Troyes, publishes an article on this subject in its issue for the present month from the pen of Dr. Pigeaux. Fruit culture, says the doctor, has in our day made real and incontestable progress. Without going back to the time of the Valois, or even to the time of Louis XIV., whose table was often worse provided with fruit than that of the ordinary amateur of to-day, it cannot be denied that our present supply of fruit is utterly inadequate to our wants. Unfortunately, the tendencies of cultivation, as applied to fruit

Adonis vernalis has flowers open, though the tufts have not yet attained their full splendour. To the same slow-opening and apparently cautious plants belongs the noble *Fumaria* (*F. nobilis*) now in flower; the yellow American Dog's-tooth Violet (*Erythronium americanum*) has been sent us by the Colchester New Plant Company during the week, but we have not noticed it in flower in London gardens.

Primrose "Purity."—Among the richly-hued and prettily-laced Primroses now in our gardens there is enough beauty to make whole parterres gay with these flowers alone. Purity is not distinguished for either its size or richness of colour; on the contrary, it seems the smallest of the varieties of the common Primrose, and it is supposed to be the whitest as yet in cultivation, though the white is only primrose-white after all. It, however, flowers profusely, and has quite a sparkling effect among its kind or among other flowers of the season.—V.

Floral Effects in Norway.—Early in summer, say the middle of June, the country about Trondhjem is of a vivid velvety-green, like that afforded by Moss in this less rainy country. This lovely hue is brightened up by extraordinary masses of wild flowers, among which broad patches of bright colour, furnished by acres of wild Pansies, Ragged Robin, &c., growing in families, are conspicuous. Many of the houses in the country have turf roofs, and the myriads of wild Pansies growing upon them and all looking one way are very striking. Later on in the year I have seen miles of the high fjelds or fells, 1500 to 2000 ft. above the sea, covered with Sundews. I have seen the flora of the Alps in full glow, but, though the species are, perhaps, more numerous, the effect of the masses of flowers is not so striking as in Norway. A grey-bearded Lichen gives a venerable aspect to many of the Pine forests.—P.

Short-leaved Yucca (*Yucca brevifolia*).—This tree-like species, in its ultimate floral growth, or final expansion into its flowering state, attains from 10 ft. to 30 ft. in height, and from 8 in. to 2 ft. in diameter; bark thick and rough; branches from 3 ft. to 6 ft. in length; leaves short, narrow, and dagger-like, crowded at the ends of the branches, and having finely saw-toothed edges; the masses of white, nodding, Lily-like flowers are closely set at the ends of short root-leaves of from 4 in. to 6 in., so that it occupies but a small space of ground. This will prove one of the most ornamental and desirable of Yuccas. The fibre is said to be as fine as silk and very strong, readily taking the aniline colours. This class of liliaceous or aloes-like plants very providently store up their treasures of starch and sugar to a great amount preparatory to their flowering and fruiting, which, for the most part, is every other year. The large, vigorous, and tender flower-stem buds are often cut off at an early period of growth, and roasted or boiled by the natives as a delicious dish. Dr. Palmer has observed that this plant, having once set its heart on blooming, is not so easily banked by the hand of man. Being decapitated, the parent plant bequeaths the acquired fortune to the eldest plantlet previously provided for an emergency, and the heir takes up and carries out the last will and testament of the departing parent, prematurely blooming in its stead.—A. KELLOGG.

Flower Gardening in Norway.—This is not much pursued in the north of Norway, so far as outdoor gardens are concerned, and the window conservatories are the only ones known. The climate forbids the cultivation of any but the hardiest outdoor flowers; but Roses on their own roots are plentiful. I was much surprised, however, to see *Delytra* spectabilis coming up in June in a garden as far north as Hammerfest. Hammerfest is in latitude 70°, and the most northerly town in Europe. On the hills behind it the Silver Birch creeps along the ground, almost like Ivy; and the natives say that they have eleven months of summer and one month that is not summer. Flowers are a passion with the northern Norwegians, and it is touching to see how their climate teaches them to love them. Failing flowers, in some of the houses it is customary to strew fragrant Fir tips about the floors, and I have also seen them strewed in the path of a funeral. Flowers, either in pots or in vases, are often placed on tombs in the churchyards.—P.

Three Good Daffodils.—*Narcissus bicolor*, *N. Horsfieldii*, and *N. Empress*, all of which are now in bloom, are three of the best of the large yellow-cupped kinds. The perianth segments are white, and the cups a rich golden yellow as bright as that of an *Altamanda*. These are three of the most distinct and beautiful of all the *Pseudo-Narcissus* or Daffodil section, and ought to find a place in every garden.

ACCORDING to Mr. Schwarz, of Lyons, between 5000 and 6000 varieties of Roses have been named and catalogued.

growing, seem to lag farther and farther behind the end to be aimed at by trying to produce fruit of exceptional size, and of a price which can rarely be remunerative, high as it undoubtedly is; but fruit culture, as adapted to the wants of the age, ought to seek to produce fruit of moderate size in sufficient abundance to suit moderately filled purses, by furnishing to commerce a certain quantity of early fruit, a large supply of fruit in proper season, and a still larger winter stock. What is necessary to supply this pressing want? First of all, we must make the very utmost of all the fruit trees which we cultivate at present in such large numbers. In order to arrive at this result, we must plant them farther apart than we do now, and absolutely proscribe the system of oblique cordons placed at the distance of only a few feet. We must also abolish the method of growing fruit trees in the form of spindles, pyramids, &c., which only serve to amuse children; but it is to be feared that these practices have laid too firm a hold on our fruit growers to be easily eradicated. They now practise these methods of training to show their talent; in a few years hence they will only be found in schools, where they will be exhibited for the sake of pointing out their defects. The desire to grow fruit of excellent quality, and of beautiful form and colour, and above all, to have trees that will bear early, has caused the almost universal rejection of natural stocks, or grafts on natural stocks, which is one of the weaknesses of modern fruit growers. Without totally rejecting the system of grafting on the Quince or paradise stocks, we must, for market supplies, come back to the free stock. With proper pruning and training a tree on the free stock can be made to bear in six years, and sustain its powers of production of fruit for half a century at least, while grafting it on its congener gives trees which only bear during some five-and-twenty years. Without old trees we cannot have fruit that will keep and export well. We have been following a wrong tack, and it will be both wise and profitable to adopt a more rational practice. In the culture of free stocks, it is indispensable not to plant them in soil having only a depth of 15 in. or 18 in. Good vegetable mould, 3 ft. or 4 ft. in depth, is not too much for a fruit tree which is to live and bear for, let us say fifty years. With vigorous trees to choose from, trees that have not been enervated by too early production, that have come of a good stock, and that have been properly pruned, of a good form, with plenty of room for the passage of the air, we may count on a sufficient and lasting yield, which is, after all, the most desirable point. Experience has shown that fruits with pips will not flourish in certain districts, while stone fruits on the contrary succeed admirably. Now-a-days, no one in their senses would plant Chestnuts in calcareous land on which the Walnut seems to thrive and attain enormous proportions. A grave error, which cannot be too clearly pointed out, consists in giving the worst part of the land to fruit tree growing, the best portion by far being devoted to flowers and vegetables. In a poor soil trees soon degenerate, and the most careful culture will not suffice to maintain the production of fruit at its proper level. The clever Montreuil growers know only too well the value of the town manure which is consumed there to neglect the use of such an aid. Fruit growers will do well to imitate them, and above all to match as they do the adaptation of the different varieties of fruit to the peculiar qualities of the land they cultivate. We must resist the temptation to introduce new varieties of fruit trees into a plantation, except indeed as an experiment. For a similar reason we must avoid the worthless varieties which our forefathers planted in their ignorance of what was really good. Ground taken up by worthless trees is simply a continual source of loss.

In virtue of the principles laid down above, we deprecate the system of cultivation which only allows of trees being grown which are cared for by trained cultivators. One of the complaints to be urged against modern fruit growers is evidently the system of pruning at present in vogue, and which has been carried to an extreme by the majority of those who practise it. To such a pitch has pruning now arrived, that it is held to be synonymous with cultivation. We frankly declare that this assertion is erroneous. A properly pruned tree, that is to say, pruned with knowledge

and circumspection, of which our best practitioners give every proof, ought easily to satisfy the wants of all amateur cultivators, but in the hands of unpractised or amateur growers it may be affirmed that it will never return during the whole of its short existence, the half of the sums laid out upon it. What fault could we not find with the system of reversing the natural order of vegetation by curving the branches downwards towards the soil, of the grafting of fruit buds, of the cutting of leaves, and of the twisting of shoots. These modes of procedure are looked upon as constituting a real progress in fruit culture, but, on the contrary, they are a mistake. Without in any way wishing to abolish amateurs' small gardens, let us make the cultivation of fruit what we have already made the cultivation of the Vine, and let us no longer be afraid of devoting the best part of our land, even of our corn-growing districts, to the growing of fruit. It would soon become largely remunerative. But it must not be thought that it is only necessary to cover large surfaces of land with fruit trees well fitted for the particular soil and climate of the locality chosen, and then fold our arms and trust in Providence; far from it, for an orchard of only a few acres requires the assiduous care of an experienced and laborious cultivator. The management of a good orchard, including the gathering and the storing of the fruits, the packing and transport at the proper time to those parts of the country which require them, is certainly no sinecure, but an occupation worthy of a man of enterprise and intelligence.

FRUIT CULTURE IN KITCHEN GARDENS.*

In growing fruits I do not condemn the system followed in market gardens—quite the contrary, but that system cannot be carried out successfully in private gardens, from which vegetables are expected to be supplied all the year round. In most cases kitchen gardens are planted with trees in rows, between which vegetables are grown. If the gardens have boundary walls, that having a south aspect is generally planted with Peach, Nectarine, and Apricot trees. I train my Peaches and Nectarines on Seymour's plan. Let us begin with a maiden tree planted when the leaves begin to fall; the ground is then warm, and it will make roots, and get established before winter. As soon as the buds begin to move the following spring cut the shoots back to three eyes, and when broken train one young shoot to the right and another to the left horizontally, leaving the centre one perpendicular. About June the centre shoot should be stopped, which will then strengthen the side shoots. In the spring following cut the upright shoot again back to three eyes, retaining one additional shoot on each side. By cutting back from year to year the requisite number of shoots is obtained to complete the tree. As regards summer pruning, as soon as the trees make shoots about an inch long, disbud or thumb-prune them by taking off all the young shoots where there is no fruit, except the lowest one upon the bearing branch, and that at the extreme point of it. This end shoot is allowed to grow about 3 in., and is then stopped; and the buds by the fruit are all broken off to about four of their bottom leaves, so as to make a cover for the young fruit until the time of thinning, when those little spurs are taken away—that is, such as are not wanted, and the others are retained with the fruit that is left. Thus we encourage the growth of the shoot for fruiting next year, and no other. All shoots on the lower sides of the branches should be rubbed off. Morello Cherries require similar treatment. They are generally grown on a north wall, but standards planted in rows also do well along with other trees. When in fruit they must be netted.

Pears may be planted against an east wall, and Plums on one facing the west. I prefer horizontal training in the case of Pears. If the young tree be what is termed a maiden, cut back to three eyes, train the shoots—one right and the other left, and one upright. The second year cut back the leader to about 11 in., so as to induce a break about 9 in. from that of the last year, still keeping an upright shoot for the stem, and rubbing off it all eyes, except those required for shoots, so that

* Read by Mr. Roser at the Wimbledon Village Club Gardeners' Society, March 24.

the tree may have a clear 9 in. of stem between every tier of branches. When fully established, summer-prune the top part of it first, say to the extent of about one-third. In about a fortnight give a second pruning, and in a fortnight after that clear the bottom or third part. This helps to strengthen the bottom part of the tree, which is invariably the weakest. Should the trees be unfruitful, root-prune them, more particularly the tap-root. Plums may be trained horizontally, or on the fan system. One thing is important, *i.e.*, if a good fan-shaped tree be required, and that is, it should be headed back sufficiently to get the requisite number of shoots, for if allowed its own way too long, great difficulty will be experienced in getting it again into good shape. Apples in rows, to be trained as espaliers, require about the same treatment as Pears on the walls trained horizontally. Sometimes they are trained in the form of a goblet, a method which keeps the centre open. The branches should stand about 9 in. apart and should be spurred-in every year, thus forming a thrifty tree. Another method is the bush system of growing them; let them be thinned sufficiently to keep the branches from crossing each other, and spur them annually. Thus treated they make neat compact trees. For Plums the bush form is best. Where Pears are planted in open quarters I prefer standards with their branches bent down; this can be done by fixing an iron hoop at the bottom, and tying the shoots down on it with a piece of string. Young trees often grow very vigorously, which they may be allowed to do until a sufficient quantity of branches has been secured; after which, if the tree proves unproductive, it must be lifted, and, after carefully pruning the roots, re-planted. Another way of restricting the growth of a too vigorous young tree is to dig well under it and cut the bottom roots; in fact, all trees that are to be kept within certain limits by pruning and training, cannot have too great attention paid to the state of their roots. Where the ground is suitable I prefer free stocks; some like the Quince stock for Pears, but if they are grown on free stocks and have the same attention paid to their roots as to their branches, good crops of fruit will always be obtained; and, when the trees have acquired a good fruiting condition, manure, applied both in a liquid and solid state, will add to the size of the fruit. Apricots, with the exception of situation, require similar treatment to Plums.

Birds and Gooseberry Buds.—During the period snow was deep on the ground the birds picked all the eyes from the shoots of my Gooseberry trees, and the result is long shoots, perfectly bare of both leaves and fruit; under the circumstances, what is best to be done—should the shoots be cut back to one eye, or should the whole shoot be removed? As I cannot net my trees, what is the best way to protect the buds in winter? The birds perfectly swarm here, and as to scarecrows they attract them rather than frighten them, as they seem to know their presence indicates food.—HARRISON. [Birds have been more than usually destructive to buds of Gooseberry and other fruit trees this winter. As the bushes in question have sustained so great a thinning, the shoots should be pruned back to any eyes left to induce the trees to make strong growths for another year. A mixture of soot, quicklime, and a little clay—the latter to make it stick—should be applied to the bushes in the autumn by means of a syringe or garden engine. Birds dislike buds after doses of this kind. Another great point is never to prune the bushes in the autumn, but, on the contrary, to leave all the thinning or shortening of the shoots until spring, when any great danger from birds or spring frost is over. I have followed this plan for many years with success.—WILLIAM TILLERY, Welbeck.]

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

A Green Currant.—Black, red, and white Currants are known to all, but I have also seen a number of green Currants. They occurred in the garden of the Leusmaund, or local representative of justice at Visnaes on the Nord-fjord in Norway. The fruit was quite ripe, and tasted like a Black Currant. The time was about the middle of August.—P.

Fruit Prospects in Cornwall.—Fruit trees and bushes are unusually well furnished with bloom this year; Plums and Pears are uncommonly full; Apples have abundance of unexpanded buds, and bush fruit of all kinds is very promising. We experienced $\frac{7}{8}$ of frost in March, and had some exceedingly rough, cold winds, accompanied by hail and snow. The weather is now, however, mild and spring-like, and vegetation is moving.—H. M.

PLATE XVI.

A NEW EUCHARIS.

(EUCHARIS CANDIDA.)

Drawn by H. HYDE.

THE Amazonian, or large white-flowered Eucharis, has become so popular in our gardens, and so eminently satisfactory in almost every way, that we had scarcely hoped to have had to welcome such a graceful and desirable allied species as that which we now figure for, as we believe, the first time in this country. This new Eucharis is a native of the United States of Colombia, from whence it has been quite recently imported to this country by Mr. W. Bull, in whose Nursery, at Chelsea, we saw it flowering freely in February last. Its bulbs are longer in shape than those of the Amazonian species, and the foliage is also longer, and of a brighter green colour. The flower-scapes vary from 16 in. to nearly 2 ft. in height, and are terminated by an umbellate cluster of from three to seven flowers, and about as many short membranous brownish bracts. The individual blossoms measure about 2 in. across, the perianth segments being pure white, and gently reflexed, as shown in our plate. The corolla is smaller and narrower than that of the older species, and tinged towards its base with yellow, whereas in *E. amazonica* it is greenish. Its slender growth and narrow, reflexed, perianth segments, at once distinguish it from its allies, and as it grows and blooms freely, and is of equal duration under the same conditions as the other species, it will prove of great value, not only in the way of furnishing cut flowers, but for decorative purposes of other kinds; and, since its blooms have none of that florist-flower-like stiffness which characterises those of the older species, they will form an agreeable variety. This Eucharis is, as will be seen from our plate, quite distinct from a plant sometimes grown in gardens under the name of *E. candida*, but is evidently the same as that figured in "Flores des Serres," vol. viii., t. 783, under the same name. Our plate well represents the graceful contour of the plant, which, when it becomes more plentiful, cannot fail to rank among the most chaste and useful of all white-flowering plants. B.

The New Vegetable Market in the City.—The preliminary works for this new Market to be erected by the Corporation on the vacant land between Charterhouse Street and Snow Hill, and adjoining the new Poultry Market, are, says the "Builder," actively proceeding. The building is to be uniform in its external features with the two markets already erected, and will extend on the south side in a westerly direction to Farringdon Street, in a line with the south boundary of the Poultry Market. The new Market will occupy an area of upwards of 2 acres in extent.

The Brussels International Exhibition.—The order of proceedings at this great show is arranged as follows:—Friday, April 29, at nine p.m., Official Reception of the Members of the Jury and of the Botanical Congress in the Hall of the Hôtel de Ville. —Saturday, April 30, 9.30 a.m., Meeting of the Jury at the Exhibition in the Plan du Petit Sablon. In the evening, Meeting at the Cercle Artistique. —Sunday at noon, Formal Opening of the Exhibition; Spectacle at the Théâtre de la Monnaie. —Monday, May 1, at ten a.m., Opening of the Congress; at 6 p.m., Grand Banquet offered by the Flora Society to the Members of the Jury and the Congress. —Tuesday, Continuation of the Congress.

The Question of Names.—We notice that the "American Naturalist," a periodical written by the ablest scientific men, makes a much-needed remark on the question of scientific names. In reviewing a first book of zoology, by Professor Morse, it says:—"The objects are called by their common names. The author has had the good sense to omit the scientific names, thus rendering the book vastly more attractive and useful. Many readers are anxious to first learn the Latin names, and are too often content to stop there. The scientific name is a thing of the least importance." There is no doubt that the progress of knowledge in plants, too, has been sadly impeded by presenting beginners with a number of hard words at first.

MR. RUSKIN, according to the "Sheffield Independent," was lately asked to preside at the opening of the Exhibition of the Sheffield Society of Artists, but declined to do so, stating that no artist worth sixpence a-day would consent to live in such a town beneath a canopy of smoke, and no lover of art would take up his abode there for a million a-year.

THE SLENDER VANILLA PLANT WITH ITS FLOWERS

TREES AND SHRUBS.

THE WALNUT AND ITS VARIETIES.

To the superficial observer there is, perhaps, no fruit that promises so little choice in the way of colour, form, and size as the Walnut, but an examination of the following varieties will show that, even amongst the members of this apparently restricted class *Damo Nature* has indulged herself once more in that love of change to which we owe so many of her most charming productions. The Walnut family, *Juglans regia*, properly so called, may be divided into two groups, the Walnuts proper and the *Caryas*, which latter, by the way, only differ in some of their secondary characteristics from the first. The genus Walnut contains two species, *Juglans regia*, which produces all the edible varieties of Walnut, and *Juglans nigra*, generally called the American Walnut, with which may be associated the *Juglans cinerea* and *Mandschuria*, which are only varieties.

Let us take the smallest variety first. The *Juglans regia microcarpa* is represented in its natural size in fig. 1. It is a small tree with spreading branches and compound leaves, imparipinnate, with from seven to nine oval elliptical and sessile leaflets, entire, pointed at the top, and sometimes cusped. The fruits are spherical, and from $\frac{1}{4}$ in. to $\frac{1}{3}$ in. in diameter; when covered with the rind they are terminated by a pretty large persistent style. The outside of the shell is slightly sinuous or almost smooth, and the cotyledons very large in proportion to the size of the entire fruit. They are of a more delicate flavour than those of the ordinary Walnut. This variety is remarkable from several points of view. The

general aspect of the tree reminds us of certain species of *Pterocarya*, especially *Pterocarya caucasica*. The size of its fruit, too, separates it widely from all known species, being less than that of many varieties of Nuts. When mixed with other varieties of widely different shape and size it forms an interesting addition to the dessert-table. When mixed with ordinary Nuts it is hardly to be distinguished from them, except by the shape. As a fruit tree the *Juglans regia microcarpa* has

its points of scientific interest. Differing, as it does, from all known varieties, it shows how a single species may vary, and we are convinced that it is only a variety of the cultivated Walnut; for, if we raise it from its own seed, the results, in the majority of instances, revert to the ordinary type. The *Juglans regia microcarpa* shows that a certain type being given, it is extremely difficult to fix its exact limits, and experience teaches us every day that in practice we are continually obliged either to extend the characteristics which we at first assigned to the type, or else to form secondary types, which will group themselves round the old one, and which themselves even may form the starting-points of fresh varieties. Going still further, but still confining ourselves to the *Juglans regia*, we find numer-

Fig. 1.—Small-fruited Walnut (*Juglans regia microcarpa*).

ous varieties, some differing in shape, others in size, others in the nature of the kernel, the hardness and smoothness of the case, or difficulty with which the two halves of the shell can be separated, &c.

One of the varieties, which is most opposed in size, shape, and general character to the small species which we have just described, is the *Juglans regia gibbosa*, or Gibbous Walnut (figs. 2, 3, and 4), a vigorous tree with a straight stem, covered with an ashy grey bark. The branches are thick with the

bark of a shiny surface, and of a ruddy brown hue speckled with elongated grey striae. The buds are large and spherical. The leaves are composed of five pairs of leaflets, the top being the longest. The leaflets are oval, obtuse, coriaceous, entire, not dentated, shining, slightly bulged on the upper surface, the under surface being pale, principally on the veins, which are of a reddish yellow, and are provided at their intersection with the mid-rib with a little tuft of yellowish red hairs. The fruit is sessile, or very slightly pedunculated (fig. 2), the rind being thinish and marked towards the base with ashy-grey elevations, which, towards the top of the fruit become so crowded together as to give it some resemblance to *Juglans nigra*.

Here and there, particularly at the sides, the fruit shows a number of gibbous elevations, which at the top are prolonged into a well-defined cone. The shell is thick, hard to the touch, and strongly corrugated, on account of the deep depressions and elevations presented by its surface. The flavour of this Walnut is excellent, and the kernel is easily extracted from the shell; but, like all hard species, the shell is thick, and there is an inner deposit which considerably reduces the size of the kernel, as will be seen from the section fig. 4. In spite of this drawback, this variety, from its large size and corrugated appearance, makes an effective fruit for the table, especially when mixed with its smaller and smoother congeners. On the left hand side of fig. 4 we have inserted a representation of the top of the fruit of *Juglans regia microcarpa*, showing that this characteristic is quite distinct in the variety we are describing. The *Juglans regia gibbosa* presents another characteristic in the insertion of its fruit, which appears to be a speciality of this variety. The fruit, instead of growing upright, or, at any rate, horizontal, is always more or less pendulous whenever it is solitary.

The next variety is the *Juglans regia variegata* (fig. 5), a tree of a vigorous habit, the young branches being covered with a dark green bark spotted with grey, and often striped longitudinally with yellow. The leaves resemble those of the common Walnut; the fruit is of a light yellowish-green streaked with darker green, and reminds one closely of certain varieties of Pears which, in common with this variety, frequently have their young branches striped in a similar manner. In order to preserve the peculiar characteristics of this variety it must be propagated by grafting or layers. Fig. 6 represents the fruit and leaf of the *Juglans regia Barthérama*, which is remarkable for the form and, above all, for the extreme length of its fruit. The kernel, which is large for

the size of the fruit, is of an excellent flavour, and the shells are thin and easy to separate. It is, in fact, a good variety, which deserves to be very much better known. It is named after M. Barthère, a horticulturist of Toulouse, who accidentally discovered it growing amongst a number of other trees; its origin, consequently, is a mystery. According to M. Barthère it is very prolific, and grows easily from seed. The seedlings begin to bear fruit very early, and are ready for grafting when four or five years old. The difference presented by the leaves when compared with those of other varieties is sufficiently marked. The leaflets are thin, soft, and flat, their points being long and acuminate, so much so as to be almost cuspid. Other things being equal, the size of the leaflets is longer in this than in the other varieties of *Juglans regia*.

The *Juglans regia oliviformis* (figs. 7 and 8) is a robust and prolific tree, closely resembling the common Walnut in its general aspect, as well as by its wood and leaves, and by the odour they emit, differing only from the typical variety in the fruit, which are generally extremely small, being only from $\frac{1}{2}$ in. to $\frac{3}{4}$ in. in diameter when denuded of the husk, and but little larger before it is stripped off. When in the outer envelope the fruit presents the appearance of an Olive, whence its name. The shell is so thin that it yields to the least pressure, and is even sometimes absent on each side of the top of the fruit, as shown in fig. 7. The kernel, which fully fills the shell, is delicious. As far as the fruit goes, it closely resembles that of the *Juglans regia microcarpa* both in size and general characteristics, but the aspect of the tree and its foliage are quite distinct, and are exactly similar to those of the common *Juglans regia*, the variety we are describing having very small branches, and comparatively enormous leaves.

There are two other varieties of the Walnut which are somewhat peculiar, the *Juglans regia preparatiensis* and the *Juglans regia serotina* (fig. 9). The former variety is precocious on account of the singular and exceptional fact that it is born almost an adult, in fact, it is nothing uncommon to see a tree in its third year bearing excellent fruit. The second—*Juglans regia serotina* (fig. 9), or the Late Walnut—is peculiar for its combined lateness and earliness, two opposite qualities seldom found in the same individual; for, although it develops its leaves, and consequently its fruit, a full month later than the ordinary Walnut, the fruit ripens exactly at the same time as those of the last-mentioned variety.

The *Juglans regia cordata* (fig. 10) is another variety that merits notice from the peculiar form of the nut. The general

Fig. 5.—The Variegated Walnut (*Juglans regia variegata*).

appearance and foliage of the tree closely resemble those of the ordinary kind, and it is not until the fruit arrives at maturity that any difference is perceived. The fruit is heart-shaped, and is flattened in the opposite direction to the suture, which juts out like a flange all round the nut in the direction of its largest circumference. The kernel is of excellent quality, and the shell is pretty thick and solid. This variety is due to M. Charles Dupuy, of Loches (Indre-et-Loire).

The following Walnuts are much grown in the south of France. The Noix St. Jean and Chaberto (figs. 11 and 12) which are cultivated for the sake of the oil contained in the kernel, and the Noix Mayette, Parisienne, and Franquette, (figs. 13, 14, and 15) which are grown for the table. They are all varieties of the common Walnut, which they closely resemble, and do not, therefore, call for any special description.

We now come to several varieties which merit our attention from a scientific point of view as occupying a position midway between the two typical species of the genus—*Juglans regia* and *Juglans nigra*, the former being Asiatic in its origin, the latter American. Leaving our readers to draw their own conclusions from the facts adduced, we commence with the *Juglans intermedia quadrangulata* (figs. 16, 17, and 18), a vigorous tree relatively low in size, in consequence of the branches spreading

through the weight of the fruit. When young the fruit is somewhat angular, and entirely covered with stiff reddish hairs, and is surmounted by a well-developed bifid style, which is somewhat persistent. As the season advances, the angles become more marked, and by the time that the fruit has reached its full size they become sensibly rounded and the surface becomes rough from the remains of the bases of the hairs which are left behind. On taking off the rind the shell is found to be covered with irregular thorns, reminding one of the fruit of the *Juglans nigra*. The shells are just as hard and as difficult to separate as those of the last-named species, which it also resembles in the kernel being inedible. The origin of this variety is interesting. M. E. A. Carrière, of the Jardin des Plantes, having made a sowing of the seeds of the *Noyer de Montbron* (*Juglans regia heterophylla*), three of the plants differed most notably from the rest. As they arrived at maturity their characteristics

became more marked, and so much resembled those of the *Juglans nigra* that several botanists came to the conclusion that some of the seeds of this variety had been mixed with the others. M. Carrière, however, dug round the trees, and luckily found the Walnut shells still adhering to the root, leaving no doubt whatever that the new variety had sprung from seed of the *Juglans regia heterophylla*. There are several

Figs. 2 and 3.—*Juglans regia gibbosa*.

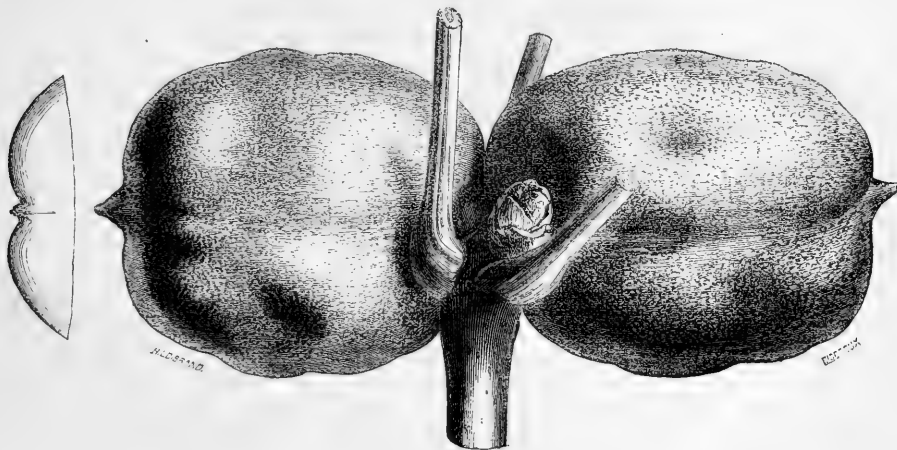

Fig. 4.—*Juglans regia gibbosa*.

nearly horizontally, and having very few ramifications. The wood and bark resemble those of the common Walnut. The leaves are very long, attaining a length of 15 in. or 16 in., and even longer. The leaflets are thin, tender, denticulated, strongly veined and reticulated, sharply acuminate at the top, and of a light or yellowish green. The fruit (fig. 16) is disposed in bunches, or rather in an upright spike, on a peduncle, which elongates and becomes ultimately pendent

other examples of this intermediate variety, two of which we will proceed to describe.

The *Juglans regia octagona* (figs. 19 and 20), or *Mandschurica* of M. Carrière, is another Walnut which is remarkable for the deviation of the shape of its fruit from the ordinary type. As its name implies, the surface of the shell has eight angular projections, with corresponding depressions between them. The hollows are rough and corrugated, giving the

shell an appearance similar to that of the *Juglans nigra*. A section of this variety is shown in fig. 19. The shells, although very hard, open readily. The section (fig. 19) shows that the shell, which is very thick, folds as it were on itself, and projects into the interior, forming a deep cavity on each side, while at the top the part constituting the cotyledons may be said to have hardly any existence. Again, the interior of the shell which touches the kernel, instead of being more or less rough, is smooth and even polished, a characteristic which seems to indicate a near approach to *Juglans nigra*, and, like *Juglans intermedia*, giving it the right to be considered a kind of link between the two species. Instead, however, of being a native of America, like *Juglans nigra*, it belongs to Asia, like the ordinary Walnut. It is a curious fact that it not only approaches *Juglans nigra* in its general appearance, but its habitat is on the easternmost border of the Asiatic continent.

The *Juglans intermedia pyriformis*, as its name implies, bears Pear-shaped fruit. The shell of this variety is very hard, of a greyish brown, and in its general characteristics resemble the *Juglans nigra* even more closely than the last named variety.

The woodcuts illustrating this article were purchased from the "Revue Horticole," to which we are also indebted for much information on this interesting subject.

Slow Tree Growth.—At a recent meeting of the St. Louis Academy of Science, Dr. Engelmann exhibited a section of the trunk of *Juniperus californica*, which was not quite 4 in. in diameter, and yet showed an unmistakable age of 127 years, each ring being on an average about one-fifth of a line wide. The largest growth in ten years had been about 4 lines, the smallest during a similar period about 1½ line.

End of a Celebrated Tree.—The traveller visiting the village of Lenna, in Hainault, Belgium, has always had pointed out to him an old Linden tree, on the plain where the great Condé won the famous battle of the 20th of August, 1648. A marble column well known to tourists was erected close to it, bearing an inscription by Boileau, beginning, "It was here, great Condé, that thy arm made the Rhine, the Escantail, and the Euro tremble." The historical Linden is now no more; it was torn up by the late tempest that passed over the country. An iron railing has been erected around its remains to protect them from the hands of the curious.

Berry-bearing Aucubas in London Gardens.—I have noticed a great many stray Aucuba berries on plants in the front gardens in the neighbourhood of Putney this year. A friend also tells me that he has, to his surprise, found a considerable number of berries on a plant in the back garden attached to his house. Another friend fertilised a plant artificially two years ago with bought pollen without any good results. This year he was surprised at finding berries on his plant, which he put down to his previous fertilisation, till I pointed out the numerous berries scattered about here on plants on which no artificial fertilisation had been attempted. Aucuba pollen is not, I should say, carried by bees, judging from the look of the flower and its inconspicuous appearance, but by the wind, and I imagine that the stray fruiting of old female plants can only be due to the increase in the number of male plants and to the pollen being thus drifted about.—P.

New Light on Transplanting Trees.—For many years I have had the transplanting of a great number of large trees annually, and such trees were generally dug round and prepared for transplanting several years previously, under the conviction that their future success would be thereby promoted. Within the last few weeks, however, I was induced to look carefully over all the large trees thus removed, and was not a little surprised to find that those trees dug round and lifted the same season, and generally the same day as dug round, were growing better than most of those that had been previously prepared. The only principle upon which this can be accounted for is that the one check, sudden though it be, is less injurious to the trees than the two lesser checks, with an interval between. If a tree in full vigour of health be dug carefully round, growing upon a dry open soil, and removed forthwith to other suitable soil and set, the roots cut, bruised, and mutilated though they be, will heal up and recover better than if the operation had been performed at two separate periods, as commonly practised and generally recommended. The next important matter to attend to is that of fixing or sustaining the trees against the winds, and for this purpose, after trying

many expedients, I find stones laid over their roots the best. If the top be heavy it may require two or three tons of flat stones to sustain it properly, but less if the trees be smaller. In placing the stones care must be taken to preserve 3 or 4 in. of clear space between the stones and the tree, otherwise friction might fatally injure them. In addition to adding momentum to the roots of the tree, the stones preserve moisture and keep out the drought. I have scarcely ever seen a tree fail in producing satisfactory results of growth where stones were judiciously and properly laid over the roots. The best size of trees for transplanting for immediate effect are those between 20 and 25 ft. high, and otherwise proportionable in stem, root, and branch. Trees of this size succeed at least equally well with those which are smaller. Elm, Lime, Sycamore, Ash, and Oak are the safest species to remove, and the work may safely be carried out at any time between October and April, both inclusive, but autumn planting is withal most successful.—C. Y. MITCHELL, in "Gardener's Chronicle." [Mr. Marcock has recently made extensive transplantings of deciduous trees in August with perfect success.]

Alcock's Spruce.—Instances are constantly occurring to prove that Japanese Conifers are, as a rule, hardy. One of the newer and most beautiful species from Japan is the *Abies Alcockiana*, or Alcock's Spruce. The peculiar tint of its foliage at once stamps it as entirely distinct from any other species, as the upper sides of the leaves present a golden tinge, while the under portion is silvery. In the Island of Nippon, whence it comes, it forms a tree nearly 100 ft. in height, growing on the mountain sides at about 6000 or 7000 ft. elevation.

Evils of Thick Planting.—If we wish trees to be firmly rooted (says Dr. Balfour in an address to the Scottish Arboricultural Society), we must allow the branches to spread freely. When they are so planted that the branches and leaves of contiguous trees do not interfere with each other, and thus all parts are exposed to air and light equally, the roots spread vigorously and extensively, so as to fix the plants in the soil, and to draw up copious supplies of nourishment. But in crowded plantations, where the branches are not allowed freedom of growth and exposure, the leaf-buds are either arrested or feebly developed, and the roots are of necessity injured. They do not spread, and the trees are liable to be blown over by the wind; they exhaust the soil in their vicinity, circumscribed by the roots of the trees around; their functions become languid, and thus they react on the stem and branches, so that the additions to the wood are small, and the timber is of inferior quality. In such a plantation there is a marked difference between the trees on the outside and those in the centre; the former, having their branches and leaves fully exposed on one side, grow with comparative vigour, and form excellent timber on that side of the stem where light and air are admitted; while the latter, hemmed in on all sides, are drawn up like bare poles, and produce a small amount of ill-conditioned wood. A crowded plantation, in which the trees are allowed to increase in size until they interfere with each other, cannot be easily reclaimed; for every attempt at thinning in this advanced stage of growth is accompanied with the risk of exposure to the blast, which speedily levels trees having no firm hold of the soil.

The Redwood as a Coppice Plant.—A gentleman showed, at the last meeting of the Royal Horticultural Society, a specimen of the Redwood of California (*Taxodium sempervirens*), grown near Reading, with a view of illustrating its suckering and rapid growth after being cut down, a fact which led him to think that the tree would be useful for coppicing, and also that it would be useful for Hop-poles, scaffold-poles. This character of the tree is one well known to those familiar with it in its native country.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Osiers for Boggy Land.—I shall be obliged if any of your subscribers can give me information with regard to planting some boggy land on the west coast of Ireland with Withies or Osiers. I should be glad to know the most suitable sorts to plant and also the best mode of cultivating them.—B. K.

Jaborandi.—The Barbier prizes for discoveries in medicine and botany were given by the French Academy, to Albert Robin and M. Hardy for their investigation of this new drug, the leaves of *Pilocarpus pinnatus*, a plant of the Rue family.

Rubus australis hardy.—This singular-looking shrub would appear to be quite hardy in the neighbourhood of London. In Mr. Ware's Nursery at Tottenham, it has lived out-of-doors for the past two years and now looks healthy.—R.

Bambusa Metake the Hardest Bamboo.—I am inclined to think this the hardest of its race, so far as we have tried it in England. It is commonly supposed that *Bambusa (Arundinaria) falcata* is the hardest; B. Metake retains its leaves with me well through the winter, even on heavy soil.—V.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Solanums.—Old plants of these should now be well cut back and at once planted out in a sheltered situation; they will bear without injury any frost that may occur after this time, and, if the planting-out be deferred until the ensuing month, they will not flower sufficiently early to enable the berries to become coloured soon enough in the autumn. Plants raised from seed, or cuttings, may be planted a little later; they will succeed the first batch, and will ripen their berries later in the winter.

Pits and Frames.—Zinnias, *Tropæolum canariense*, *Rhodanthe Manglesi*, *Phlox Drummondii*, *Mesembryanthemum*, French Marigolds, and *Asters*, should be sown at once for planting-out; also Cockscombs, Balsams, *Globe Amaranthus*, *Celosias*, and Egg Plants, for growing in pots.

Celery.—As soon as young plants of this are large enough to be handled they should at once be pricked out in a cold frame, where they may remain until they are finally planted out. The system adopted by some of first pricking Celery out from the seed-pans into boxes, thence to a frame, and ultimately to the rows, by which it receives a check each time it is removed, is just the practice calculated to cause it to run to seed; the fewer checks it receives, from whatever cause, the better. In preparing a nursery-bed in a frame for the plants, select a light open situation, level the ground, and tread it quite solid, on it put 4 in. or 6 in. of ashes, rammed and beaten hard so as to render it impervious to the roots; on this place 4 in. or 5 in. of rich light material, consisting of half-rotten manure and leaf-mould, the other half being ordinary fine garden soil; in this the plants will grow rapidly, and move with little injury to the roots, thus obviating any check. Put them in 3 in. apart each way, give a good watering with a fine-rosed can as the plants are put in before they have time to flag, put the lights on the frame, shade from the sun, and admit little air for a few days until they begin to root, after which give plenty of air and light, and at all times sufficient water.

Lawns, Pleasure Grounds, &c.—Where there is any deficiency in the turf on lawns through the Grass being bare, this should be remedied by sowing fresh seeds. It is often better to do such work now than earlier, as if we have the seasonable showery weather usual in this month the seeds vegetate much quicker than if sown earlier, and are sooner out of the reach of birds, especially sparrows, which, if not scared away, will frequently not leave a single seed to grow. To prevent their attacks, white thread should be strung across the newly-sown seeds, secured to small sticks, stuck in the ground as recommended for the protection of kitchen-garden crops. But amateurs must bear in mind that the means that will effectually deter one kind of bird will in all probability be wholly unavailing in the case of others; for instance, the threads just named are generally sufficient to keep off sparrows, whereas chaffinches or greenfinches, which are equally destructive to most kinds of seeds, are no more deterred by such threads than if nothing at all had been used. In the case of these, nothing is so effectual as the gun, or nets, to exclude them. Inattention to protecting seeds in some way or other often neutralises all the labour bestowed in attempting to renovate lawns in that way. Before the seeds are sown a sufficient quantity of moderately dry sifted soil should be prepared for scattering over them to the depth of half-an-inch immediately they are sown, after which run a roller over the surface when the soil that has been scattered on is dry enough not to stick to it. The constant mowing of lawns and verges in time causes the Grass to become so poor that it can scarcely exist. Where this is the case, if a mixture of three-fourths sifted ordinary loam to one of powdered lime be scattered on the surface, about 1 in. in thickness, it will greatly improve the growth of the Grass. Guano and other light but potent manures, mixed with loam, are often recommended for this purpose, but they stimulate growth too much for a time, soon become exhausted, and are very much inferior to lime, which is more conducive to the growth of close fine Grass than anything that can be applied. Where Moss grows to any extent it is objectionable, principally through the brown unsightly appearance which it has in very dry weather, and the propensity that birds have for pulling it up, in order to get at the insects that harbour in it. Lime, in this case, will be found the best antidote. When necessary, the Grass should be mown, for if allowed to get too long before that is done no machine will do the work properly. In machine-mowing, a prevalent mistake is to set the implement so as to make it cut too low, the effects of which are, that a lawn so treated takes several days, after the Grass is mown, to recover its proper appearance; and, later on in the season, when dry weather sets in, it burns so as to frequently destroy the roots. Where Crocuses, Daffodils, or similar bulbs are grown in the Grass, the tops of these should not be cut off whilst in full growth, as that precludes the possibility of the plants blooming the ensuing

season in anything like perfection. Whatever remains to be done in the shape of edging-up lawns or verges should at once be attended to. All evergreens that require cutting-in should now receive that attention; any shortening of the branches needed is best done just before they begin to grow; but on no account should they be subjected to the formal clipping process that is sometimes practised, whereby the natural habit and appearance of the plants are destroyed. When shrubs are planted so close together as to necessitate the whole or the greater part having their branches reduced, it is better to remove some of them altogether. Hollies, evergreen Oaks, *Arbutus*, Tree Box, and all Coniferous trees and shrubs should be but slightly cut, except, perhaps, branches that are taking an undue lead. Laurels, especially common kinds, may be cut in closer. Evergreen hedges, such as those of Holly, Yew, or Privet may now be cut. Where Ivy on walls is left for years without the loose unattached shoots being removed, it gets so heavy that the whole often gets torn off by the wind; another objection, too, is that when not periodically clipped in it casts its old leaves through the summer, and these get blown about by the wind, making a continual litter. In pruning Ivy, all the loose shoots should be removed, and if done now, in a few weeks it will be clothed with fresh leaves.

Mixed Borders.—A sowing of annuals should now be made; many of these, in most places, have given way to bedding plants, but still there are a number that cannot be dispensed with and that should find a place in every garden, large or small; amongst such may be mentioned Candytufts, Clarkias, *Eschscholtzias*, *Helichrysums*, *Convolvulus major* and *minor*, *Collinsias*, *Ipomæas*, *Love-lies-Bleeding*, *Lupinus*, *Mignonette*, *Nemophilas*, Sweet Peas, *Schizanthus*, Stocks, and *Tropæolums*; rapid-growing plants like these require rich soil and an open situation. When crammed under trees, in out-of-the-way places, as is too often the case, they do not, as a matter of course, give satisfaction. Another mistake in the cultivation of annuals is sowing the seeds much too thickly and thinning insufficiently afterwards. In preparing the ground, just level the place where each kind is to be grown, then sow the seeds and cover with $\frac{3}{4}$ in. of finely-sifted soil, and if some coal ashes be added, they will help to keep off slugs.

Edgings.—Unquestionably no edging looks so well as Box, but it has several faults, especially when used in kitchen gardens, it affords a harbour for slugs and snails; and, when it is found necessary to dress the ground with salt for the destruction of grubs and slugs, or for its manurial properties, or to salt the walks to kill weeds, it always stands in the way of the work being effectually done, as whatever precautions are taken, unless such a space near the edging is left undressed as to make the work only partially effective, the Box is sure to get injured; consequently, in the vegetable garden particularly, it is better to use something else, such as tiles made for the purpose, or common bricks set on edge; but the latter should be well burnt, or they will fall in pieces after frost. Where Box is intended to be planted, or where that existing requires making or mending, or where it has got too large, and the whole wants taking up and re-planting, it should be done at once, as there is no time in the year during which it moves so well as just before it begins to grow. In re-planting, the work should be systematically carried out by removing the whole of the gravel from the sides of the walks and laying it up in a ridge along the centre. The Box should then be all taken up and the roots protected; the ground should now be properly prepared and levelled, and the trench for planting on each side opened from end to end. The Box should then be divided, planting it well down so as not to leave it more than $2\frac{1}{2}$ or 3 in. above the soil, treading the ground well to the roots, after which replace the gravel and finish the operations by adding a few inches of new gravel if required. The reason why Box edging in small gardens often gets too large and unsightly, is that it does not receive regular attention in the way of clipping, or is not cut close enough. Where bricks are used, their ends should stand about 2 in. above the gravel; they are liable to get a little out of line in rolling the walks, but this is easily remedied by the use of an ordinary crowbar; insert it deeply into the soil behind any that have been pressed out of line, and wrench them back into their places, treading the soil firmly up to them; by this simple means a considerable length of either brick or tile edging can be put to rights in very little time.

Greenhouse Plants.

Plumbago capensis.—The colour of this plant, and the ready way in which it may be grown and had in bloom for cutting or conservatory decoration in the autumn, render it one of the most desirable plants to cultivate. In our flower vases it may not be quite so lasting as some others, but that deficiency is fully compensated for by the free-blooming properties of the plant, and the soft subdued shade and pleasing form of the flowers. To obtain

a vigorous growth and flowers in abundance, the plants should be turned out of pots about the middle of May, and be planted in some good soil in an open situation, where they can be well supplied with water, and treated in other respects as occasion requires. Any old plants that have been wintered should now be pruned in by cutting away the wood of last season's growth to within 2 in. of its base; place the plants in any forcing house or pit to give them a start, and gradually harden them off before placing them out in the open; plants treated in this way are in a far better condition for producing bloom in the autumn than any that can be grown in pots, while an immense saving of labour is effected.

Daphne indica.—The deliciously-perfumed flowers of the *Daphne indica* are held in the highest esteem, and yet there are few gardens in which the plant is cultivated to the full extent of its merits. Where an increase of stock is desired, the present is a good time for grafting; or cuttings taken off with a heel will root readily in heat under a bell-glass, or close propagating box. The Spurge Laurel (*Daphne laureola*) is a suitable stock on which to work it, but as its growth is much more free than *D. indica*, an unsightly swelling at the point of union frequently takes place. To obviate this, the scion should be placed as low down on the stock as possible, that the united parts may be kept beneath the soil, when the growth will be more regular. Any that require re-potting should now receive that attention, after which place the plants in gentle heat to encourage free growth. A good yellow turfy loam is the proper soil to put them in, but as they do best when rather confined at the root, unless they are very carefully watered, a very small shift should suffice. Healthy plants that have filled their pots with roots will be greatly benefited by a little manure-water occasionally while making their growth and forming their flower-buds, after which it should be discontinued.

Primulas.—As soon as these are large enough to handle, they should be pricked out thinly in pans or placed singly in small pots. A light, rich soil, consisting principally of leaf-mould or peat, with the addition of some mellow loam and sand will suit their wants in that respect; place the pots or pans containing them where they can be properly shaded, and the plants receive an occasional syringing overhead to assist them to start freely.

Calceolarias.—These will now require close watching to keep them free from aphides, insects to which they are very subject at this season. If these be allowed to get ahead, they soon disfigure the plants beyond recovery, and, therefore, fumigation should be resorted to as soon as they begin to show themselves. The tender leaves of the herbaceous varieties are easily injured, and it will be necessary to exercise the greatest care that they do not get an overdose. Two or three weak applications in quick succession are at all times better than giving much at one time. Keep the atmosphere of the pit or frame in which they are growing in a moist state, syringing and shading up early on the afternoons of bright sunny days.

Petunias have been so much improved of late as to be well deserving of pot culture. A packet of seed sown now will afford a great variety of colours, and come in very usefully in the autumn, when flowering plants are becoming scarce. Inferior kinds that may occur amongst them are sure to be acceptable for planting out in the mixed border, where their gay colours show off to great advantage. The young growth of any old plants that may have been saved through the winter if put in now as cuttings will make large showy specimens by July, a time when they are sure to be acceptable

for replacing many of the usual occupants of the greenhouse that are generally removed to other quarters at that season.

Rhodanthe Manglesii.—To afford as much variety as possible during the summer and autumn months, some of the best of the annuals should now be sown for pot culture, for which purpose none are better adapted or more beautiful than the old *Rhodanthe Manglesii*, and its more recent varieties, *R. major* and *Prince Bismarck*. Seed of these should be sown at once, and placed in gentle heat to encourage them to germinate freely, after which pot them in rich light loam in 48's, placing three plants in each triangularly near the edge of the pot. A close moist frame suits well to grow them in till they begin to show bloom, when they should be removed to light airy shelves or other elevated positions where they can be seen to the best advantage. *Martynia fragrans* is likewise a very desirable plant for greenhouse decoration, and may be sown and treated much in the same way as the *Rhodanthes*, except that, being of larger size, one plant is sufficient in a pot.

Globe Amaranthus are very brilliant showy annuals, and are admirably adapted for pot culture. If sown at once and grown on in gentle moist heat they will make fine plants and last in great perfection till late in the autumn.

Salvias.—These are indispensable where a supply of winter-flowering plants has to be kept up, and if they are required of large size a batch of cuttings should be put in at once. By growing two or three varieties a constant succession of bloom may be preserved with but slight intermission from October to the end of April, a time of year when such brilliant-coloured flowers are sure to be much valued. *S. splendens* commences to throw up its fine heads of bloom in September, and these continue in perfection till near Christmas if the plants be placed in a moderately warm greenhouse or conservatory, where they can have plenty of light and air and be kept free from damp, as they soon suffer in a low temperature or close stagnant atmosphere. The flowers are of a bright scarlet colour, and are borne in the greatest profusion at the end of every shoot, so that a few well-grown *Salvias* have a very telling effect. *S. Heeri* is a magnificent bloomer, and comes next in succession. This is quite unsurpassed among soft-wooded winter-blooming greenhouse plants, and a few arranged among the other occupants impart quite a bright cheerful appearance to a whole house. *Salvias* are not good subjects for lasting in a cut state, as the flowers of most of the varieties fall off almost immediately after being severed from the plants. *S. Heeri*, however, lasts well, and is

exceedingly effective on account of its attractive colour and the loose graceful arrangement of the flowers, that are always a great ornament to any vase. *S. gessneriflora* forms a noble-looking specimen, and well repays any attention that may be bestowed upon it. This is the latest-blooming of the trio, and keeps up a supply of its bright-coloured flowers till the end of May. To get early cuttings of the two latter varieties it is necessary to cut down the plants, placing them in gentle heat for the purpose of giving them a start. The young growth taken off roots readily and soon makes strong healthy plants that are sure to flower freely if liberally treated during the summer months. A rich, stiff, loamy soil, a fair amount of pot-room, and a copious supply of manure-water when the roots have made good progress, are the most essential conditions requisite for the production of vigorous-growing *Salvias* of large size and well clothed with foliage down to their base, without which they have only a very mean appearance.

Fig. 6.—*Juglans regia Barthereana* (see p. 352).

Stove and Greenhouse Ferns.

Gradually remove the old shabby fronds of all Ferns, as the young ones emerge and begin to unfold themselves, taking care, while doing so not to injure the latter, which, in their present tender state, is easily done. Watch closely while removing them, to see that the young fronds are free from brown scale, or that none of these pests become dislodged while picking over the plants, and fall where they have a chance of establishing themselves, or they will soon spread and re-stock the house with their progeny. To remove or disturb the scaly covering is only to set free myriads of young ones in the embryo state that are protected beneath its covering, and that when liberated, float about in the air, and alight on other plants, to spread again as soon as conditions are favourable. By exercising a little care now while removing the old fronds, these troublesome insects to Ferns may be, if not entirely got rid of, at least so reduced as to be kept under. Some Ferns are subject to green fly, while the fronds are young and tender, and where these occur they soon cripple and disfigure their growth. The safest and best way to eradicate them is to dip the heads of the plants in weak tobacco-water, and afterwards give them a shake, when the insects will fall off. Fumigation, if applied sufficiently strong to destroy them, would endanger the safety of the young tender shoots, and should therefore be avoided while the fronds are in their present immature state. When any fresh soil is placed in the house for the purpose of potting, or filling up the pockets in which Ferns or other plants are grown, it is frequently the means of introducing slugs or their eggs with them.

Those, when hatched, prey on the growth of Adiantums and other choice Ferns directly they make their appearance, and the plants are thereby seriously injured unless they are closely watched. A Cauliflower or Lettuce leaf, saturated with tallow, or a little bran in heaps, forms a tempting bait for them; but the best way is to search for them by candle light, examining closely the plants they visit, as they will generally be found feeding there in

preference to such common fare as any of the above. It is still the practice with many cultivators of Ferns to cut away the whole of the old fronds at one time, instead of removing them piece-meal, as they become shabby, or the young ones attain sufficient size to take their place. Such a course has a very weakening effect on the plants, and is a very frequent cause of many roots perishing, thus producing an enfeebled growth for a long time afterwards. The supply of water should be gradually increased as the young fronds gain in size and root-action becomes more vigorous, a time when they can scarcely be kept too wet, unless the soil should happen to be unsuitable or the drainage defective. Tree Ferns ought to have their stems kept well moistened, either by syringing them freely, or by pouring water down their stems, so as to insure them being kept in a properly moist state. If these be allowed to flag or suffer in any way from want of water, the young fronds are almost certain to become crippled and deformed, besides the great risk incurred of losing the plant altogether. Any of these, recently planted or not properly established, should have their stems bound up with Moss, and be frequently syringed, so as to keep them constantly moist, and encourage the formation of roots. The atmosphere in Fern houses can hardly have too much moisture in it at this season, and therefore, every available surface should be well damped down. Syringing overhead is of great benefit to the plants, and this should be done just before closing the ventilators, early in the afternoon, whenever the day is dry and sunny. Avoid as much as possible drenching the heads of *Gymnogrammas*, or such as are liable to become disfigured by a course of treatment so suited to

many other varieties. Where the above have to be grown with the general collection, a slight bedewing overhead must suffice. Shading must now be resorted to, but only for a few hours during the early part of the day while air remains on, as when sunshine is too much excluded the fronds are not so stout and serviceable for cutting as they are when more fully exposed. Where shades of a permanent character have to be used, as is sometimes unavoidably the case either from the size or situation of the house, and the difficulty attending the fixing and working a temporary one, the material to be used on the glass should be of the thinnest description, and such as is not of a very perishable nature. A slight coating of lime-wash, neatly applied to the outer surface of the glass, is perhaps the best for the purpose, as the rays of the sun are moderated and subdued without excluding the requisite amount of light for building up and consolidating growth. To fix the lime for the whole of the summer, it should be obtained in a fresh state, and then slaked in hot water, to be afterwards reduced to a thin liquid of about the consistency of paint, or ordinary white-wash. Two handy men should be employed to lay it on so that it may be done quickly, and with a little care and skill in using the brushes, it may be made to look so neat in appearance when seen from the inside of the house, as scarcely to be distinguishable in appearance from ground glass. The wash should be laid on thin, and before it has time to dry be dabbed over with a clean half-worn brush, so as to leave it free from smears and streaks. A shading

put on in this way requires no further attention for the remainder of the season, and gradually comes off in the autumn from the action of the weather, just as the plants require all the light and sun that can be afforded them.

Sub-Tropical Plants.

Slow-growing varieties of these, such as *Wigandias*, *Uphedra*, *Acacia Iophonantha*, *Melicanthus major*, and others of that class, should now be pushed on in heat as fast as possible, in order to have them of sufficient size to produce an early effect after

Fig. 16.—*Juglans intermedia quadrangulata* (see p. 863),

being planted out. Ricinus, Maize, Chilean Beet, and even Solanums do best sown any time this month, as they quickly attain their full size after being planted out, and furnish with much finer foliage than they do when confined in small pots, or in any way checked in their growth. The chief beauty of the Ricinus, when planted as single specimens, is in having the stem well clothed with large handsome foliage down to the surface of the soil; but this can only be done by sowing late, and keeping the young leaves constantly growing. R. Gibson should not be overlooked when ordering seeds of these, as the colour of the foliage is very striking, almost equalling the rich tint of Dell's Crimson-leaved Beet, or that of the Amaranthus. This and the Melianthus major as edging form a very striking and effective group, and suit each other well as to height. Cannas not yet started, should at once be divided and placed somewhere under glass to get them on the move before planting them out. An old half-spent hot-bed, or any pit or frame where they can get a little heat will answer the purpose admirably. Shake some rotten leaf-soil amongst the roots for them to lay hold of, so that they may be lifted at planting time with large balls without receiving a check. Coleus, so much used for carpet-bedding and other purposes, may now be struck with great rapidity in any place where they can have strong moist heat. A single leaf and bud is quite sufficient to form a plant, if taken with a piece of the old stem attached, and when so made, they will root in a few days. Alternantheras will strike with the greatest freedom at this season in any hot-bed, frame, or similar position where they can be kept close and moist. The best

way to manage these and other plants of similar character, of which large quantities may be required, is to put some light sandy soil in the frame, and prick out the cuttings in it at about 2 in. apart, and let them remain in that position till wanted. When thus treated, the lights can be gradually withdrawn to harden them off, and much labour is thereby saved in potting or handling them several times over, as would be the case if the cuttings were inserted in pots or pans in the ordinary way. The beautiful dwarf-spreading yellow-variegated *Mesembryanthemum cordifolium* strikes best on shelves in moist houses or pits near the glass where it does not get too much sun. In propagating boxes, hot-beds, or other closely confined places away from the air, it is apt to damp off on account of the quantity of moisture contained in its leaves and stems. This is a bad subject for transplanting, and must therefore be potted; but the smallest sizes will do for the purpose, as it forms but very little root. *Pyrethrum Golden Feather* should be pricked out if at all thick, as, when planted out fully exposed to the sun and air after being drawn up in seed-pans or boxes, it soon shrivels up and dies, or makes but little progress. To grow any fine-foliated plants really well, and get them to develop the rich colours of their leaves to perfection, it is necessary that the soil of the beds in which they are grown should be rich and open, that the roots may penetrate it freely. As there will be but little time to spare by, and by to prepare beds for the different plants intended for them, any work of this nature that is necessary should be done at once. There is no comparison between the colour of *Alternantheras* in poor shallow soils, and such as are grown in well-prepared beds moderately enriched with mild decomposed manure. The old *Pyrethrum*, too, brightens under the effects of good living, as do most of the coloured foliated plants, if fully exposed to the influence of sun and air, so necessary in bringing out and developing their delicately beautiful tints.—J. SHEPPARD, *Woolverstone Park*.

Hardy Fruits.

SINCE my last communication under this head, the weather has been in all respects most favourable to the unfolding of fruit blossoms, and though Apricots were injured by the severe frosts of the third week in March, a sufficient quantity have set for a moderate crop. Peaches are setting well, Pears are full of blossom, that on walls being already fully expanded and looking most vigorous. Plums are literally covered with bloom, and early Cherries the same, the only exception being Apples, which are not flowering so well as was expected at one time, though from what we have seen elsewhere the scarcity of Apple blossom is local only, so that on the whole—should severe frost not visit us and blight our hopes—another fruitful season may be anticipated. It will not yet be safe to dispense with wall-coverings, as they should remain down for some time after the sun is up, for the greatest injury is always caused by the direct rays of the sun on uncovered trees before the frost is off. Grafting should be completed forthwith, as both stocks and scions will soon be too far advanced for the operation. Occasionally look over those that have previously been grafted, as the frost sometimes loosens the clay, and causes it to crack and fall away, and it is important that this should be renewed, and the grafts kept air-tight; also remove any shoots made by the stock as soon as perceived. Peaches, Nectarines, and Apricots will now require disbudding, which should always be done before the buds attain much size, or by their removal a severe check is given to the trees; when done early, they may be finally disbudded, but if left till the shoots are 1 in. or 2 in. long, a few only should be removed at intervals of a few days till all are completed. If green fly put in an appearance, as is frequently the case at this stage, dust the trees over with Tobacco powder, applied through a flour dredger, or syringe them with soap-suds, and directly the fruit is set wash the trees with a syringe or garden engine to dislodge the fallen blossoms, and loosen any which still adhere to the fruit. The fruit sometimes sets in clusters, and when such is the case it should be thinned out immediately. Strawberries are now beginning to grow freely, and should be mulched with stable litter on the first opportunity, previously clearing them of all weeds, either by hand or hoeing. Personally, we disapprove of hoeing or digging Strawberry beds after they are first planted, as thereby so many of the best roots are destroyed. Our system of culture is as follows:—New plantations are made on deeply trenched and heavily-manured ground every third year; they are well mulched with good manure always once, and sometimes twice a year, and this in addition to keeping them free from weeds and runners, and an occasional watering in dry weather, is all the attention they receive, and we never fail to have an abundance of fine fruit. Strawberries, like most other hardy fruits, do best in firm or rather hard ground, and should never be disturbed with either spade, fork, or hoe, till the plants are done with. A piece of ground should now be prepared for the planting-out of the forced plants; from such a plantation the earliest and best runners may be had for next season's forcing, and, in addition, some little fruit in the autumn. The

flowers should be kept off, and, if requisite, be regularly watered till thoroughly established. Vines in the open air will, about this time, require to be disbudded; usually the shoots are in such clusters that, unless some are removed, all are worthless. From practical experience we strongly incline to the belief that in the more favoured districts as to climate, open-air Grape culture might be made remunerative, by the bestowal of a very little labour, in the form of disbudding, regulating the growth, and thinning-out of the bunches; at least, the system undoubtedly merits a fair trial at the hands of persons interested.—W. WILDSMITH, *Heckfield*.

Trees and Shrubs.

Lose no time in finishing forest planting, as this month may be said to terminate the season. Conifers and other evergreen trees and shrubs may now be safely transplanted; their roots should be exposed as little as possible to the air, and they should never be allowed to get dry; if the weather be hot and dry at planting time, water both foliage and roots freely, and mulch heavily. Pampas and other Grasses, herbaceous plants, and Ferns will succeed if shifted now. Wherever timber or underwood was cut last year, the ditches should be cleaned out and new ones made wherever water is stagnant. Level and otherwise repair wood rides on which timber has been hauled during the winter. Wood rides should be kept 3 or 4 in. higher in the middle than at the sides, so as to render them dry, and unless the sub-soil is gravelly and porous a ditch should be made on each side not less than from 2½ ft. to 3 ft. wide at top and from 2 ft. to 2½ ft. deep. Clear Ivy off forest trees, and even on underwood stools of large size it should not be allowed to establish itself. All gates and stiles should be put in order.

Hedges.—Any hedges still untrimmed or "unpleached" should now receive that attention. All gaps should be planted up with a double row of Quick and Hornbeam; where ground game is numerous, bitter Willows succeed best. *Salix Kerkis* should be selected; it is a vigorous grower, and is disliked by rabbits. In case of a hedge being very patchy and weak, and, in itself, an insufficient fence against cattle, the following attention will make it secure:—Stretch along the line of the fence, about 18 in. above the ground, a strand of strong wire fastened with staples to stakes set up about every 5 yards apart, and the hedge should be trimmed or pleached down to the height of the wire, and afterwards allowed to grow over the wire so as to form a back-bone, as it were. Any new hedges that are still to be planted should be put in forthwith; the ground on which they are to stand should be trenched 12 in. or 15 in. deep, and from 4 ft. to 4½ ft. wide; bad soil or stones should be taken out, and good soil or chopped up turf added; a slightly raised bed or bank is preferable to planting on the level; this may be formed by placing the soil taken out of the ditch on to the bank, putting the best soil in the centre, and keeping the turf on the sides, which should be from 12 in. to 15 in. high and 3 ft. wide at top. The ditch may be from 3 ft. to 3½ ft. wide at top, and 2½ ft. deep; the plants should be put in about from 5 in. to 6 in. apart. For coppice, a mixture of Hornbeam and Quick forms a good hedge, planting one of the former to six of the latter. Hornbeam grows well under the drip of trees; it will bear pleaching, and throws up strong vigorous shoots when cut close to the ground. Young hedges should be allowed to grow two years after planting before they are cut down close; after cutting, allow them to grow two more years; then trim them into shape, encouraging a thick broad base and narrow top. The first cutting into shape may take place when the hedge is about from 15 in. to 18 in. high, allowing it to rise 3 in. or 4 in. every year until it has attained the desired height, which should be from 4 ft. to 5 ft. high and about 3 ft. wide at bottom. The best tools for trimming hedges are those made by Polwarth (late Sanderson), of Dunse; Nos. 60 and 70 are the most useful sizes for small hedges, or for topping large ones; Nos. 80 and 90 are stronger knives, and are used for "breasting" and cutting over old hedges; the cost of these knives is from 5s. to 6s. each.

Thinning of Plantations where necessary should be pushed on; better sacrifice the approaching growth on the nurses than allow the Hardwood to be choked up another season. More injury is done throughout the country by under-thinning plantations under twenty years old than by over-thinning them; old woods are easily irreparably injured by over-thinning; but in the case of young healthy-growing plantations the case is very different. Bark stripping may be begun in another fortnight, or less if the weather keeps mild; therefore, it will be necessary to forward all work in progress as much as possible before the busy season of Oak stripping begins; all coppices or woods intended to be thinned should now be gone over and marked, taking care to mark only the most unhealthy and badly shaped trees that are injuring better ones; thin rather freely round the outside, particularly where hedges are too much overhung by trees.

Nursery Work is unavoidably very backward, on account of the continued wet season. Where the soil is heavy, it has been quite impossible to proceed with the transplanting of young trees into nursery rows; but as soon as the land is dry enough, this must receive prompt attention, and take precedence of all other kind of ground work. All Conifers or evergreen trees and shrubs intended to be planted out this season should be lifted and heeled in in a shady and sheltered place in the nursery. Finish sowing seeds of forest trees and shrubs; Conifer seeds may now be sown when opportunity offers. Graft ornamental trees. The destruction of weeds, if done now, will save double expense further on in the season; when weeds are thoroughly kept down in the spring months, they seldom get the upper hand in summer and autumn. If the annual stock of peat, leaves, or turf has not yet been collected, this ought to be done as early as possible; where road-drift and parings can be had it is invaluable for planting trees and shrubs in. I collected about thirty cartloads of this last year, and had it stacked so as to keep it dry, and during this winter I have found it most useful when planting young Conifers, ornamental trees, and shrubs; instead of being obliged to put their delicate fibrous roots into a soddened soil, they were covered with this compost dry and sweet for the roots to feed on at once.—*GEORGE BERRY, Longleat.*

CUCUMBER CULTURE IN THE OPEN AIR.

By picking out, as it were, the warmest months of the year, and assisting the plants by means of shelter and other favourable conditions, anyone having a warm garden may enjoy Cucumbers from June to the middle of October. Choose a sheltered warm situation in any part of the garden, with a southern aspect, then remove 1 ft. or 2 ft. of soil over a surface a yard or so wide, fill up the space so formed with some decomposing leaves, manure, tan chips, Coconut fibre refuse, or anything that will generate warmth. Cover this over with the soil removed, and either sow the seeds on or set plants in this warm bed. The latter is by far the best course, as by this means much time is saved, and the heat of the artificial bed quickly pushes on the plants. Therefore, the seeds should be sown under glass, if possible, or in some very warm place, at least three weeks before this growing bed is formed in the open air. As soon as the plants have formed a rough leaf beyond the two smooth cotyledons, they should be potted off singly and deeply, so as to bury all the stem up to the cotyledons. By the time the plants have filled a 60-size pot full of roots, they will be in the best possible condition for planting out on the artificially warmed bed already described. After planting, it is a good practice to cover the plants over with a bell-glass, cloche, or hand-light, or any other kind of glass protector, until they get a firm hold of the soil. This helps them the sooner into free growth and plentiful fruit-bearing. But still the glass covering may be dispensed with. In that case, however, it will hardly be safe to plant out until the end of June, or if planted earlier, a flower-pot or old hat-box, or a double paper protector had better be placed over them every night until all danger from frost is over. One of the simplest protectors for such plants is a wooden box 6 in. or 8 in. square, and 10 in. or 1 ft. deep, with the upper side covered with oiled calico drawn tight. But, by planting strong plants late, we may dispense with all these coverings, and also with the artificial terrestrial heat, although the latter undoubtedly affords a powerful stimulus to growth.

Out-of-door Cucumbers may either be grown on the ground, or slightly raised above it on trellises of various sorts, or they may be trained on walls and fences, or other vacant places. The surface of the earth is, however, perhaps the best position for them, for there they have congenial warmth, and the leaves are strengthened by the evaporation of moisture from the ground. The foliage as well as the roots are also readily watered in such a position, and the roots are so shaded as to protect them from being scorched or scalded by the sun. The necessary training, stopping, and cutting of the fruit are likewise easily attended to when the plants are allowed to ramble freely over the surface. Out-of-door Cucumbers are generally allowed more freedom of growth than those in frames. In the latter, the plants have what may be termed a hard time of it; for what between fruit-bearing and the pinching back of each shoot to the next joint beyond the fruit, they are subjected to a compound pressure. But in the open air, as the object in view is a quantity of small, crisp, sweet, eatable fruit, rather than a few large ones, the plants may be very much left to themselves, with the exception of a weekly overhaul to out, water, &c. Cucumbers also do well trained up south or west walls, planted either on the top of a few spadeful of fermenting materials, or simply in warm borders. Well watered, carefully stopped and trained, many of the shorter frame Cucumbers will do fairly well in such positions, whereas the long varieties, such as the Stockwood Long Ridge, the Long Prickly, &c., do exceedingly well. The plants must be

watered freely at the roots if placed against a south wall, and should be soaked overhead at least once or twice a day.

Even those who have no garden need not despair of growing their own Cucumbers for pickling, salad, and eating, on a stone yard or balcony. The varieties already named, as well as the Short Prickly and Cluster Gherkin, may be grown in pots, boxes, or vases, and would prove quite as interesting, and almost as ornamental, as many of the common plants often found in such positions. In almost any soil Cucumbers will grow, provided it is open and rich enough; though, of course, the orthodox mixture of two parts of turfy loam and one of rotten manure is the best for those in pots and boxes out-of-doors. See that the pots and boxes are well drained, a matter even of more importance than the soil, for the latter can always be enriched by house sewage or manure-water. Care must, however, be taken not to over-stimulate out-of-door Cucumbers, as gross growth is apt to invite mildew, one of the greatest enemies to Cucumbers in the open air.

D. T. FISHER.

A NEW MANURE.

A FERTILISING agent, called the Floral, has lately been brought out by a French house, under the patronage of the French Agricultural and Horticultural Societies. It is a chemical compound, the constituents of which I do not know, but in which the presence of nitrate of soda and ammonia is apparent; and one of the principal points (next to its efficacy) is its strength and the ease with which it can be applied to plants, &c. With amateur horticulturists this is a great consideration, especially where it is desired to employ manure in the house or conservatory. I had seen the "Floral" highly spoken of in some French paper, and determined to get a sample, which I tested in various ways last year, and my experience leads me to recommend it strongly. It is in the form of a powder, which should be dissolved in water for use. There are four special compounds, each of which is adapted for different plants. Thus No. 1 is suitable for (among others) Agaves, Ageratum, Aloes, Calceolarias, Cinerarias, Narcissis; and, among vegetables, Beetroot, Celery, Cabbage, Lettuce, Radish, &c.; No. 2 is used for Arums, Atriciolas, Chrysanthemums, Ferns, Geraniums, Myrtles, Sweet Peas, &c.; No. 3 for Asters, Begonias, Centaureas, Clematis, Fuchsias, Lobelias, Rhododendrons, Roses, &c.; and No. 4 for Camellias, Jessamines, Grasses, Crocus, Green Peas, Rhubarb, &c. It does not do to use the compounds indiscriminately, but the directions should be followed closely. I tried the experiment of watering the same kind of flower in different pots, with all four mixtures, and found that those not recommended for the particular plant had a different effect (sometimes less apparent, sometimes a bad effect) from that produced by the specified mixture. The powder is neatly packed in small tin boxes, and the four kinds of "Floral," labelled and in separate tins, are sent out together in a large case. The smallest-sized tins contain 125 grammes ($\frac{3}{4}$ lb.), and are sold at—Nos. 1 and 2, 1 franc (10s.); Nos. 3 and 4, 1 $\frac{1}{2}$ franc (1s. 6d.). The powder should be dissolved in water in the following proportions: of Nos. 1 and 2 (2 grammes) about 30 grains, or half a teaspoonful to a litre of water (about 1 $\frac{1}{2}$ pints); and of Nos. 3 and 4 the same quantity to twice the amount of water. Only a very small quantity of the solution should be given to each plant, and it should be applied to the soil, and not poured on the leaves; say, to pots about No. 32 size, two wineglassfuls of the mixture twice a week. At this rate the $\frac{1}{4}$ lb. packet would suffice for 2500 doses of Nos. 1 and 2, and 5000 of Nos. 3 and 4. For plants in the ground a larger quantity will, of course, be necessary, but it is astonishing how far a small quantity of the manure will go. The necessary waterings with fresh water should of course be continued in the interval between the use of the manure. For watering plants in the open, with a rose, a weak solution of the powder may be used, in the proportion of half a teaspoonful of Nos. 1 and 2, and half that quantity of 3 and 4, to nine quarts of water. So far as I have tried the "Floral," I can recommend it as an excellent manure. Its advantages are apparent from what I have said, and I have only to add that it may be obtained of Messrs. Alfred Dudouy & Co., 38, Rue Notre Dame de Victoires, Paris. The carriage from Paris is not very much.—"Country."

Asphalte v. Wood.—On Tuesday, at a meeting of the City Commission of Sewers, held at Guildhall, the long-vaunted question of asphalt or wood as a street pavement, and especially in the City of London, was brought prominently under consideration. On a division, and after the advocates of each mode of paving had spoken on the subject, 24 voted for wood, and 22 against it. We are convinced from observation of the wood pavement, that it will in the end disappear in reference to duration, as compared with asphalt. By the aid of hydrants the asphalt can be regularly washed, and the dusty filth which makes the air of cities so disagreeable and unwholesome in dry

weather, may be completely removed. With a wood pavement perfect cleanliness is impossible. The wood is also much the most expensive, and the process of laying down is also exceedingly offensive. The motion on wood pavement, as felt in a vehicle, is not so agreeable as that on asphalt.

Cultivated India-rubber and Cinchona trees.—At a recent meeting of the members of the Society of Arts, Admiral Ommanney in the chair, Mr. Markham gave a description of the cultivation of Caoutchouc-yielding trees in British India. The first instance of the conversion of the Caoutchouc-yielding tree from a wild to a cultivated state occurred somewhat more than a year ago. In April 5, 1850, he submitted a scheme for the collection of plants and seeds of the various species of the febrifuge Cinchona plants in South America and their introduction into India. At that time Cinchona plants were noncultivated. Now, there were extensive Cinchona plantations yielding larger per-centages of febrifuge alkaloids than the trees ever did in their wild state, and extending over the Neighrighy Hills, the lower slopes of the Sikkim Himalaya, and the higher ridges of Ceylon. From these plantations, some belonging to Government, others to private companies, about 140,000 lb. of bark was annually imported into this country, and the yield was rapidly increasing. The permanent supply of an indispensable medicine had been secured, and it had been brought within the reach of millions who formerly could never procure it. Thousands of lives would by this means be saved, and the material wealth of India, and Ceylon would be increased by the addition of a valuable product to their list of exports. In 1870 Mr. Markham came to the conclusion that it was necessary to do for the India-rubber or Caoutchouc-yielding trees what had already been done with such happy results for the Cinchona trees. While the trees yielding quinine and the febrifuge alkaloids only grow wild on the slopes of the Andes, and all belonged to one genus, the Caoutchouc-yielding trees were of several genera, and were found in the forests of India, the Eastern Archipelago, Africa, Madagascar, Mexico, and Nicaragua, as well as in South America. Owing, however, to the enormous demand for Caoutchouc, the most reckless fellings were now going on in all the tropical forests which yielded this valuable product, and the time had now come when plantations must be formed of Caoutchouc-yielding trees in order to prevent their eventual destruction and to provide for a permanent supply. It was well known that Caoutchouc was now used for an infinite number of purposes. The imports into England in 1874 from South America were 70,866 cwt.; India, 9341; Borneo, 7101; Africa, 6380; and Madagascar, 5984. After giving a lengthy explanation as to the cultivation of these trees, Mr. Markham, in conclusion, remarked that so far as British India was concerned, the necessary measures had now been adopted with a view to secure a permanent supply of the best Caoutchouc.

NOTES AND QUESTIONS—VARIOUS.

—The Best Winter Pine-apple.—Twenty-five years ago I pronounced the Black Jamaica to be the prince of winter Pine-apples, and twenty-five years of subsequent experience tell me that I spoke the truth. The Black Prince is showy and fairly good, but it can only be compared with the Black Jamaica; the Pine-apple that comes nearest to it is Prince Albert. Mr. Thomson, of Clonfert, says no Pine in mid-winter can approach the Black Jamaica, a statement which I can fully substantiate.—R. GILBERT, *Burghley*.

Weather in the Eastern Counties.—Yesterday (April 10) and to-day we seem to have got back to the unpleasant weather we seemed to have escaped. Yesterday it was blowing hard and raining the greater part of the day; last night we had a slight frost; this morning frequent heavy snowstorms, and the thermometer now (11.30 a.m.) stands at 36°, very discouraging for gardeners without glass to shelter their favourites.—J. G. NELSON, *Aliborough Rectory, Norwich*.

Rhododendron caucasicum.—A small plant of this which stood out fully exposed all the winter, began, during the severe frost and snow in March, to expand its buds, and now it is splendidly in bloom, though only 18 in. high; it has twenty-three trusses of flowers on it all open. The trusses, too, are large in proportion to the size of the plant, and the foliage being good, it is just now a very beautiful object.—J. C. GASSON, *Thorne, near Doncaster*.

Hydrophyllum Plants.—A few years ago I received from Canada, among other plants, two species or varieties of *Hydrophyllum*. As they have increased very much, it is necessary to thin them, and it is a pity to throw them away if any of your readers would like to have a root. They grow very well in moist soil, but would no doubt prefer the margin of a pond, where the peculiar rhizome can creep over the surface of the dry bank, while the roots penetrate to the moist ground below. I shall be happy to send portions of it to any one who will communicate with me as far as it will go.—W. H. MORSEY.

White Calville Apple.—This variety, as seen in Covent Garden, imported from France, is both large and handsome, but when grown in England, except in favoured localities, it only attains a middle size. Yesterday (March 27) Mr. Wilson, gardener to Earl Lindsay, showed me half a dozen fruit of this variety grown on a south wall at Uffington. They were of good size, as yellow as gold, quite plump and fresh, and their flavour was delicious. This variety, Mr. Wilson assured me, is a constant bearer, and he is enabled to have fruit of it all through the month of April.—R. GILBERT, *Burghley*.

The Californian Buckeye (*Pavia californica*).—This interesting flowering tree was introduced so recently as 1857 from California, where it is reported as occurring in some districts in considerable abundance, and attaining in sheltered valleys heights of from 30 to 40 ft. As seen in our gardens it is a slender-branched bushy shrub or miniature tree, amply clothed with small bright green palmate leaves, with from five to nine leaflets. The flowers are white, sweet-scented, and borne on erect panicles from the points of the shoots; they are produced in great profusion on young moderate-sized plants, and when in full perfection, which is generally about the middle of July, they have a fine effect. Though as yet comparatively seldom met with in collections, it is a very distinct-looking handsome tree, admirably adapted for a specimen on a small lawn or shrubbery border, and as such it will doubtless soon become popular. From its unfortunate tendency, however, to grow late in autumn it cannot be recommended for every situation; but when planted in such as are sheltered, and in light dry soils, so as to secure early growth, and the thorough ripening of the wood before winter sets in, there are few districts in which it will not only grow freely, but fully reward the cultivator with an annual display of its showy blossoms.—"The Gardener." [This is, indeed, a beautiful tree, and wholly distinct in aspect from any other low tree with which we are acquainted. This is particularly true of its winter aspect when full grown or old. It ought to be tried in many gardens in the warmer parts of these islands.]

Irish Yews with Single Stems.—When in a young state a very small amount of attention is needed to remove surplus leaders, and thus keep these to one main central stem. This renders the plants much more valuable, and saves endless trouble in after years in keeping them in shape. In many nurseries this early training is too often neglected, and, as a consequence, when the plants become large, they are blown about by every gale, and the labour and trouble in rectifying matters after a storm is a severe tax upon both time and patience. Were I now called upon to make extensive plantations of these and similar Conifers, I would discard every plant that had more than one main stem, for I have had so much labour at various times and places where this early attention had been neglected as to thoroughly impress upon my mind its importance. When plants of *Arbor vitæ* are used in ornamental grounds for forming hedges—for which they are well adapted—the advantage of confining them to one main central stem will be appreciated as they advance in growth. It is true those plants that are furnished with several leading shoots may appear to the uninitiated more bushy and better furnished than those kept to one stem, but in this, as in many other matters, appearances are not to be trusted, for whilst a plant confined to a single stem will annually improve in value, another, on which no such attention has been bestowed, becomes annually more troublesome; and, if much exposed to winds, the evil is increased tenfold.—E. H.

Oregon Woods.—Mr. Dufur has collected in all thirty-three varieties of Oregon woods, which have been gathered by his personal efforts, the means for bringing the same out of the mountains and forests having been furnished by a few gentlemen at Portland, among whom are Messrs. R. R. Thompson, Ladd, Corbett, and Failing. We ("Californian Horticulturist") noted one specimen of Fir, a transverse section cut 130 ft. from the ground, measuring 7½ ft. across; another cut 200 ft. from the ground measured 5 ft. across. A Spruce section cut 98 ft. from the ground measured 7½ ft., and at 143 ft. it shows a section of 5½ ft. in diameter of the tree. A Laurel measures 42 in. across, and Alder 40 in., a Chittim-wood 14 in., a Larch 5 ft. A Silver Pine is on exhibition, a remarkable wood that finishes equal to Satin-wood, and is only found in mountains at an altitude of 4000 ft., which is said to be only known in the Alps and in our Cascade Mountains. A kind of Hemlock Spruce, found near the coast, makes very fine cabinet work. Of course there are specimens of the beautiful Oregon Maple, and of many other woods we need not name.

Number of Conifer Seeds in a Pound.—An inquirer asks the number of seeds in a pound of some of the leading Conifers, and how many he could make grow. We can easily give the number of seeds, but we are entirely at a loss to say how many of these he will make grow, even if all the seeds are perfect, which is rarely the case. One who has had ample experience in growing the young trees will be far more successful than a novice—the nature of the soil, its condition depth of planting, shading, &c., as well as the work of some depredators, having much to do with the results. The following numbers were obtained by Mr. Douglass, of Illinois, an extensive and successful raiser of evergreens, after much careful weighing:—Norway Spruce, 58,000 to the pound; Hemlock, 100,000; White Pine, 20,000; White Spruce, 160,000; Scotch Pine, 69,000; Austrian Pine, 28,000; Cembra or Stone Pine, 2700; Balsam Fir, 45,000; American *Arbor Vitæ*, 320,000. European Larch has about 70,000 seeds to a pound, Pears and Apples about 12,000 seeds.—"Albany Cultivator."

SOCIETIES AND EXHIBITIONS.

ROYAL WESTMINSTER AQUARIUM AND WINTER GARDEN SPRING SHOW,

APRIL 12 AND 13.

THOUGH a good exhibition, this was by no means so well supported as the very liberal prizes offered would have led one to expect. Among the subjects of more than ordinary interest, attention may be directed to the twelve superb fruits of imported St. Michaels smooth-leaved Cayenne Pines, furnished by Messrs. Webber & Co., of Covent Garden. These varied in weight from five to eight pounds each, and were plump and in every way well-proportioned fruit, as fresh, to all appearance, as if just cut. Messrs. G. Paul & Son showed several round baskets of very large and richly-coloured buds of Maréchal Niel Rose; and the Cyclamens of Mr. H. Little, of Twickenham, were of very excellent quality; as were also the twenty half-specimen Azaleas, staged by Mr. Ratty. Of Auriculas, Mr. Jas. Douglas and Mr. Charles Turner were the principal exhibitors. Mr. Dean's improved Primroses were also very attractive; and the same may be said in reference to the lovely hardy flowers contributed by Mr. Parker, of Tooting.

Stove and Greenhouse Plants.—In the class for twenty specimen Azaleas, Mr. Ratty, gardener to H. Thornton, Esq., The Hoe, Sydenham Hill, was first with well-bloomed plants, among which was remarked Flag of Truce, an excellent double white kind; Jules Margottin, paper white; Concina, bright purple; Madame Marie Van Houtte, double creamy white, striped with rose; Roi Leopold, fiery rose; Duc de Nassau, bright satiny carmine, and others equally good. Mr. Charles Turner furnished well-bloomed standard-trained plants, among which we noticed Francois Devos, double scarlet, and one of the very best of its class; Pelargoniflora, soft rose; Rubens, scarlet; Madame A. Verschaffelt, white, crimson in the edge, and striped with rose; Reine des Pays Bas, white spotted and striped with lilac, and others equally good. In the class for nine Azaleas, Mr. B. S. Williams was first with the open class for nine examples of Stella, Mars, elegans, Eulalie Van Geert, Borussia, perfecta, and others equally well managed. In the amateurs' class, for six specimens, Mr. R. Ward stood in the foremost rank. The first prize for six forced Rhododendrons was awarded to Mr. Child, who contributed R. Veitchianum, an elegantly-frilled petalled white kind, R. Everestianum, R. purpureum elegans, R. Brayanum, and R. Princess Alice, all in good condition. Orchids were represented by some good plants, the best in the amateurs' class being those from Mr. J. Ward; among them were observed Odontoglossum Blandii, O. Pescatorei, Dendrobium Farmeri, Lycaste Skinneri, Trichopilia suavis, and Cypripedium villosum, all in excellent condition. In the nurserymen's class Mr. B. S. Williams furnished good plants of Vanda, tricolor and V. suavis, Dendrobium densiflorum, Lycaste Harrisonia, Dendrobium Wardianum, and Cypripedium villosum, the latter bearing seventeen flowers.

Cyclamens and Cinerarias.—Cyclamens were shown in magnificent condition; indeed, it is questionable whether finer specimens than those staged by Mr. H. Little on this occasion have ever been seen at any exhibition. They were literally masses of fresh foliage and well-shaped richly-coloured flowers. Mr. Little had the best groups of fifty and twenty-five plants respectively, the second awards going to Mr. R. Clarke and Mr. James. In the nurserymen's class Mr. E. Edmonds was first with well-grown plants, and the same exhibitor obtained a certificate for a basket of large-flowered seedling varieties. Cinerarias in good condition came from several exhibitors. Mr. James, of Isleworth, had the dwarfest and most perfect half-dozen, the flowers of which were well-shaped, brightly coloured, and of good substance. The practice of naming these varieties should however, we think, be abolished, inasmuch as they cannot be perpetuated true from seeds, and Cinerarias worth pot-room are scarcely obtainable in any other way. Messrs. Johnson & Sons had a good collection, but more lax in habit and flower than the last. Mr. J. Hepper staged six large and well-flowered plants, to which a third prize was awarded.

Hardy Flowers.—These gems of the early year were well represented, the best collection of them being that furnished by Mr. Parker, of Tooting; among these we remarked Doronicum austriacum, with large golden-rayed flowers; Anbrictia purpurea grandiflora, a dense mass of bluish-lilac flowers; Saxifraga Stracheyi, of which we hope soon to give an illustration; and S. media, both good forms of the broad-leaved section. Associated with these were Orobus verus; two varieties of Tricelcia uniflora; the lovely sky-blue Anemone pinnata; the rosy variety of Scilla campanulata, Fumaria bulbosa, Iberis inflifolia, and Primula elatior, Golden Plover. Mr. R. Dean, who was second, furnished a group of smaller plants, among which were examples of Myosotis dissitiflora; crimson and yellow Primroses and Polyanthus; yellow, blue, and maroon Pansies; golden Wallflowers, Alyssum saxatile, rose Dielytra, double white Daisies, and Primula cortusoides anemona. Mr. Hooper, of Bath, also staged a group of Pansies, Primroses, Polyanthus, Hyacinths, and Double Daisies, the Pansies especially being large and fine. Auriculas.—Mr. Douglas had well-grown plants in the class for fifty varieties, among which we noticed a distinct dark purple Self, named Topsey (Kay), a welcome addition; also Robert Trail, Mary Ann (Pletcher), Marie (Chapman), Colonel Champeys, Eliza, and a lovely blue Self, named Fornosa (Smith). Among the Alpines in this group, we noted Edgar (Turner), crimson purple; Beatrice, purple; Brilliant, Maroon, Brown Queen (Turner), a reddish-maroon, and quite distinct in colour. Mr. Charles Turner had also a choice and well-grown collec-

tion, in which we remarked Colonel Champeys, Diamond, Prometheus, Charles Ferry, John Gair, and others of equal merit, the colours being very brilliant throughout. In the class for twelve show varieties, including the Douglas contributed a well-grown stand of show varieties, including the following, viz.—John Waterston (Cunningham), Fernoss (Smith), Col. Champeys, Robert Trail (Lightbody), Competitor (Turner), Alderman Wisbey (Turner), Admiral Napier (Campbell), Lancashire Hero (Cheatham), Alderman C. Brown (Headley), and George Lightbody (Headley). In the class for twelve show Auriculas Mr. Charles Turner was first with the following kinds, all in admirable condition, viz.—Ann Smith (Smith), Beron (Turner), Portia (Turner), lovely Ann (Olliver), Mary Taylor (Turner), General Neill (Trail), Charles Perry (Turner), Prince Albert (Levin), Meta (Turner), Drake (Levin) (Turner), Alderman Wisbey (Headley), and Col. Champeys (Turner). Mr. James furnished a group of small but well-grown plants. In the class for six varieties, Mr. Douglas had a well-arranged stand, in which we remarked Charles Napier (Lightbody), General Neill (Trail), Topsey (Ray), John Waterston (Cunningham), Robert Trail (Lightbody), and Alderman Wisbey (Turner); the Rev. H. V. Dombtrain was second with well-bloomed examples of General Neill (Trail), Waterloo (Hogg), Col. Champeys (Turner), Pizarro (Campbell), Apollo (Dickson), and Conqueror (Popplewell). In the class for twelve Alpine and fancy auriculas, Mr. Turner had a very even and well-grown group. Mr. Douglas, Mr. Dean, and Mr. James had also well-grown collections. Some very pretty gold-laced Polyanthuses came from Mr. Turner, Mr. T. Petridge, Mr. Hooper, and Mr. J. Odell, the varieties, and especially those staged by Mr. Petridge, being very brightly coloured and distinct. Mr. R. Dean sent a very attractive group of Polyanthuses, among which we observed White Bedder, creamy-white, with a yellow eye; Conqueror, crimson, with a bright yellow eye; The Bride, white, with a yellow eye; Yellow Bedder, yellow, with an orange eye; and Victory, sulphur, with an orange eye, these being very distinct and beautiful. Mr. Douglas contributed an attractive group of white, lilac, and crimson varieties of Primula anemona, and some large, well-formed, and richly-coloured Pansy blooms came from Mr. Hooper, of Bath.

Miscellaneous subjects.—Messrs. Rollison, of Tooting, furnished a large and attractive group of standard Azaleas, Orchids, choice Palms and Ferns, to which an extra prize was awarded. Mr. B. S. Williams also contributed a well-arranged collection of Orchids, Ferns, Palms, Fitcher Plants, and other novelties, to which similar awards were made. Messrs. Standish & Co. sent choice groups of cut Roses and decorative plants, among which were specimens of Adiantum gracillimum, A. Farleyense, and Trichomanes demissum, and some large potsful of Lily-of-the-Valley, admirable examples of good culture. Mr. Charles Noble, of Bagshot, staged a group of Clematis, among which we noticed several new and distinct varieties. Kelpie's Bride is an eight-spiced free-flowering Clematis, with lustrous satiny white segments; Madlle. Tarrini is a rather small, but very charming variety, with a pale blue and purple; Proteus is, as its name infers, a very variable form, having double or semi-double flowers of a dull greenish-purple colour; Daniel Deronda is a new variety in the way of President, but rather lighter in colour. Mr. H. Bennett, of Stapleford, sent a choice group of new Roses, including Cleopatra, a new seedling Hybrid Perpetual, of good form, with close, revolute, bright, rose petals; Marie Guillot, a new white Tea; Perle des Jardins, a deep sulphur, Tea-scented variety, very chaste in the bud state; and the new salmon Tea, Jean de la Roche. Messrs. Cutbush & Sons sent an attractive group of Cacti, Palms, and other decorative plants. Messrs. W. Paul & Sons, of Waltham Cross, sent a very large group of pot Roses in bloom, backed by pyramidal Ivies in pots, and fringed in front with tricolor, Zonal, and other Pelargoniums.

Fruit.—In the class for two clusters of Grapes, new or old, Mr. Sage, gardener to Earl Brownlow, Ashridge, was first with superb clusters of Black Alicante; Mr. J. Allward, gardener to J. G. Barclay, of Hatfield, being second, with good Lady Downes; Mr. H. Polkes was third, also with Black Alicante; and Mr. J. Hepper, of the Elm, Acton, and Mr. E. J. Miles, gardener to Lord Carington, Woburn Abbey, had extra prizes awarded for new forced clusters of Black Hamburgs in good condition. Mr. G. T. Miles had a second prize in the open class for new or old Grapes, with early forced Foster's Seedling; while Mr. Hill, of Keele Hall, had an extra award for well-kept bunches of Black Alicante.

Pines.—These were confined to twelve splendid examples of imported smooth Cayennes from St. Michaels, sent by Messrs. Webber & Co., Covent Garden. These were in every way noble fruit, weighing from 5 to 8 lbs., and perfect in form and colour; indeed, with such superb fruit to market at this season it is not difficult to see why home-grown fruit cannot possibly compete with these either in quality or price.

Strawberries.—These were represented by three good dishes of fifty fruits, the first prize being awarded to Mr. A. Phillips, gardener to A. Moss, Esq., Chadwell; Mr. Ward, gardener to Earl Radnor, being second; and Mr. George Sage, third. The varieties were—Sir C. Napier, Sir J. Paxton, President, Princess Dagmar, and Keen's Seedling.

Cucumbers.—These were represented by nine brace of good average quality, the first prize being awarded to Mr. E. Cherry, of Leigham-court Road, Streatham, for a long-necked dull green variety named The Hero; Mr. Bates, of Appley Hall Gardens, Atherton, was second with Appley Favourite; and Mr. W. Rapley, of Clapham, third with very large and coarse examples of Tender and True.

Souvenir du Congress Pear.—At the recent meeting of the Western New York Horticultural Society, Mr. Geo. Ellwanger said: "After several years fruiting we can say that for large size, beautiful form and colour, it is without a rival among recent introductions."

"This is an art
Which does mend Nature : change it rather ; but
The Art itself is Nature."—SHAKESPEARE.

ORCHIDS FOR GENERAL CULTIVATION.

THOSE who have had anything to do with Orchids for any length of time cannot fail to have noticed the increasing favour with which this beautiful class of plants has been looked upon of late years by lovers of flowers. Fifteen or twenty years ago large collections of Orchids were very limited in number, while small collections of them, such as we frequently meet with nowadays, were almost unknown. The chief reason of this was that they were supposed to be more difficult to manage than most other plants, that they required a very high temperature in which to grow them, and that none but those who were well acquainted with their management could hope to succeed in their culture. The exhibitions then showed as good Orchids as those shown at the present day, but they were chiefly large-growing showy kinds, not easily affected by heat, our smaller-growing cool-house gems being seldom met with. Some, even then, talked in favour of a cool house; but it would seem that the 50° spoken of for a cool house Orchid was seldom interpreted to be the same as that recommended for other plants, for the thermometer was oftener found at 70° than at 50°. There are cases in which amateurs, unaided, commenced the culture of these plants with little or no knowledge of their habits and requirements; and the success of the few who had begun in this way encouraged others; the lowering of the price, in consequence of numerous importations, also helped to popularise Orchids. I cannot call to mind a single instance of failure in the case of any one who had thus undertaken the growing of Orchids, although sometimes experience has been bought at the expense of an odd plant or two; amateurs have invariably found that as their collections grew larger, so did the knowledge of their requirements, and, what is equally essential, their love for them has also increased. The knowledge that Orchids do not require so much heat as was at one time considered necessary, has also given a fresh impetus to their cultivation. It has been known for some years past that the very means formerly employed in the culture of some of the more beautiful Orchids, such as *Odontoglossum Alexandræ*, *O. Pescatorei*, *O. novium*, the *Masdevallias*, and others, have had the effect of banishing them from collections, and this has led many to try cool treatment. Many of those who undertook Orchid growing for the first time commenced it under anything but bright prospects. One cultivator with whom I am acquainted, unaided except by a few hints given from time to time by myself, began his collection in a small suburban conservatory; nevertheless, his plants one and all have done remarkably well, and he has now an excellent collection. Another, unassisted, successfully began Orchid culture in his Fern-house; and I could advert to many instances of a similar kind to show that Orchid growing is fast advancing in public favour; in short, there are now scores of Orchid-growers for every one that existed a dozen years ago. Seeing, therefore, that there are so many new growers, so many beginners, so to speak, in Orchid culture who are always glad of a little advice on the subject, I purpose furnishing a few remarks from time to time on such cultural matters as my experience enables me to do; and as a forecast of what may follow, let us now allude to

Shading.

While we cannot be too grateful to collectors for any information which they may furnish respecting the habits, peculiarities, and surroundings of Orchids in their native habitats, it becomes everyone, before putting information thus acquired into practice, to consider carefully how far it would be practicable under their particular circumstances. From such sources we learn that many of the *Lælias*, the Guatemalan and Mexican *Odontoglossums* and *Oncidiums* are found growing in

the full blaze of the sun, and hence it has been inferred that these plants do not require shading, but that is a mistake. I am aware that in one or two instances where large batches of a few kinds were growing together, they were got through the summer with little or no shading, chiefly owing to the construction and situation of the house, the care taken in giving air, and that they appeared to be benefited by the treatment; but my experience has been unfavourable to such a course, particularly when tried in the case of an amateur's collection, in which plants of different habits are mixed together. Orchids growing in their native habitats, even if exposed to full sunshine, have the advantage of being in exactly the proper condition to enable them to withstand its effects; they have also a free circulation of air continually playing around them, and growing, as many of them do, on the larger branches of trees, they have at least a few twigs above them, and these, by constantly changing their relative positions, owing to wind waving, prevent the plants from being scorched. Under glass the case is very different; the plants themselves are motionless, so is the air, or nearly so, and our summer not being their summer, they are unprepared to withstand the bright rays of the sun, particularly coming upon them through glass; what they want is all the light which they can get, not to be burned by the sun. Could any advocate for growing Orchids without shading stand perfectly motionless in a close house facing the sun for about ten minutes, he would probably alter his opinions in that respect. It cannot be too distinctly understood that every house in which Orchids are grown should be shaded; the next question is what sort of shading should we employ. Some speak favourably of colouring the glass late in spring, and leaving the colouring matter on till winter, but against that there are insurmountable objections. In the first place, the colouring matter being on the glass day and night, bright days and dull days alike, excludes much of the light which is so essential to the well-being of the plants. It also wears off in places where it is most needed, and it is at least but a clumsy makeshift, only to be recommended where movable shading cannot be employed, or to afford shade where blinds do not meet. The kind of shading generally used throughout Belgium, consisting of stout square laths or pieces of wood woven together with cord, the distance between each lath being about its own thickness, answers admirably there; but in England, where even in summer we often have a period too bright to permit of our dispensing with blinds, and yet not bright enough to warrant such heavy shading it would not be satisfactory. A plan of shading the glass obliquely by means of fixed wooden shades is to be tried in the Wellington Nurseries this summer, and it looks as if it would be successful; but in the meantime we must employ to the canvas roller blind, which should be so arranged that by means of supports fixed to the outside of the house it does not rest on the glass. Thus managed a current of air passes between the blind and the glass, by which the temperature of the house is kept in a condition suitable to the plants. Care should also be taken in selecting the material for the blinds to procure it of a sufficiently close texture, but not so thick as to exclude much light. The person entrusted with the care of the shading should also be informed that it is not put there to be let down in the morning and drawn up again in the evening in a mere routine fashion, but it is to be let down only when it is required to protect the plants from the sun's rays, and drawn up by degrees as they go off the house.

JAMES O'BRIEN.

THE VINE PEST IN LONDON GARDENS.

THE greatest pest that has ever invaded the gardens and vineyards of Europe is at our door. The Vine pest (*Phylloxera*) which has destroyed so much valuable property in French vineyards, is slowly and unobserved working destruction in some of the best-managed gardens in this country. Mr. John Wilmot's market garden at Isleworth is second to no other in the country as a fruit garden, and it is infested with it. The finest vineries about London are those in Baron Rothschild's gardens at Gunnersbury, and there are none more skillfully managed; yet here the *Phylloxera* has laid fatal hold of one of the finest plantations of Vines that existed. The pest is the worst with which we have ever had to deal, not only from its

destructive powers, but from the fact that its presence is not visible to the naked eye, and that it seems to get thoroughly established on the Vines before much harm is noticed. It is supposed to be established in thousands of vineries in England now where no one suspects its presence. The Vines may to the ordinary observer seem in fair health, yet their roots may be a mass of the small knots which mark so clearly the presence of the enemy. There comes a time, however—after the pest has been at work for a few years—when growth almost ceases, and the berries drop off just about the time they ought to be beginning to colour. When we gave the life-history, remedies, and all that is known concerning the Phylloxera, we did not imagine there would be such practical demand for the information in this country, though an isolated case or two had been published; now there is reason to believe that it has become a real danger to every Vine-grower. The natural history of this pest, illustrated with many accurate engravings, will be found in Vol. VII., p. 158, of THE GARDEN.

LAYING OUT SMALL GARDENS.

VOLUMES have been written upon landscape gardening—but we sometimes think that such works are of benefit chiefly to those who need them the least—and that no rules, however explicit, can guide a person in laying out and planting grounds, who has not a natural love of plants and a natural taste to assist in their selection and arrangement. The shortest distance between two points—a straight line—is the very best direction for streets or the limits of property; but it ought never to describe the boundaries of sylvan walks, of flower-beds, or of the lawn. Nature abhors straight lines. How beautiful soever may be the trees, shrubs, and flowers, and how skillful soever their display—straight marginal lines give a laboured, artificial look that it is the first aim of the good gardener to conceal. Not to stumble over the post while we avoid the pillar—lines that are too curved are also objectionable. The walk or carriage-drive leading to the public road should, of all paths, be the most direct; and in these any curve sufficiently decided to lead one perceptibly out of his way and suggest the wish to "cut across" should be avoided. In by-paths, leading to shady nooks, rock-works, rustic arbours—the curves, if only concealed by foliage so that their entire outline does not present itself to view, may crook without limit. The impression that we do not know whither we are going, or to what beautiful surprises we are being led by these obscure paths, if ever so faintly produced, is one of the best proofs of taste and skill. Arranging flower-beds, walks, grass-plots, trees, shrubs, mounds, vases, and the like in pairs is another senseless proceeding, as if every object were so unfinished in itself that it must have a counterpart similarly placed to perfect it. But if we adopt the ungeometrical style of gardening, as there are no rectangles that require sentinels stationed in every corner—the family of twins will be likely to receive at the outset "marked coldness." In distributing plants, let us avoid dotting the ground at regular distances, as if it were laid out in squares, and each square were allotted one tree or shrub for its centre and only ornament. The effect is meaningless, and far more distasteful so in the indefinite than in the rectilinear plan, since in the latter it is in accordance with everything else. Groups of trees and shrubs of varying sizes (always proportionate to the extent of the grounds) may be placed here and there, inclining on the whole, however, not to obstruct the view from those parts of the dwelling most frequented, and yet so placed as to conceal, except by glimpses, as far as possible the public road and all boundary lines, so that the actual termination of the ground in all directions is obscured, and one may revel in fancied seclusion. These groups must not, however, be planted as if they were one huge tree, but in some instances connect with other groups—while occasionally they may be relieved by lower-growing specimens in the immediate vicinity. But of all violations of susceptibility to all that is beautiful—to delicacy of feeling and good judgment, the introduction of statuary to the grounds about one's home is the most absurd. Bronzed animals, such as deer, dogs— or even lions and panthers—may, if placed in thickets or half exposed, be admitted; but white, nude statues of gods, goddesses, or mythical heroes, flouted out in the broiling sun, or left to freeze and thaw during winter's snows, are painfully inappropriate. Who ever did select his favourite spot near one of them? Their general aspect is not reposeful—and we should select our nook so that many trees and shrubs might intervene to exclude these unhappy, friendless things from view ere we gave ourselves over to balmy, perfumed air—the deep shadows and the—the other enchantments of summer nights and fair gardens

In selecting plants, our first thoughts should be about their hardiness, especially if a professional gardener be not employed, and the proprietor is unable or unwilling to give, or is incapable of giving, discriminating attention himself. Trees not perfectly hardy for the locality may thrive for a season or so; but they will be sooner or later killed or so injured as to destroy their beauty. New and alluring Evergreens, whose hardiness has not been thoroughly tested, are often causes of disappointment. We cannot afford to ascertain in the garden by experiment whether trees are hardy or not. It takes too long for them to grow—or rather, too long for others to grow to fill their gap. Arrange flower-beds in a south or south-east exposure. Do not attempt complicated designs, or even angular figures, of any description. Reserve all study upon this subject for the selection of carpets and oil-cloths—wall-paper and frescoing. Make the beds conform to the paths, leaving grassy margins between, always wider than the lawn-mower. If flower-beds are cut out of the turf, it is quite easy to change them from one shape to another—to make them larger or smaller, or to re-turf and construct new ones in different places. Unless the ground is naturally rich, we are well rewarded by removing 18 in. of earth, and replacing it with leaf-mould and loam—old manure and sand, in the proportions needed. All should be thoroughly intermixed and leveled smooth, ready to receive the plants. Box and other edgings are very pretty, if well kept—but there is nothing to compare with a clean, velvety turf for margins. The best floral effects are only obtainable when the flower-beds are contiguous. To soften the effect of too much colour, make the tropical bed central, and here display by the use of such plants as the Wigandia, Rheum, Dracena, Palm, Hibiscus, Catalpa, Agave, Yucca, Aralia, Solanum, Musa (Ensete), Ficus—colours and foliage that will lend dignity and character to all. An occasional low-growing tree, such as the Crataegus, Pavia, Chionanthus, Rhus, Gleditsia, Cornus, Cercis, Alnus, Magnolia, Salisburia—or shapely shrubs, as Spirea, Rhododendron, Azalea, Calycanthus, Cydonia, Hydrangea, Mahonia, would be in keeping. Whatever subjects be selected—whatever plan decided upon for the flower-beds—let us not forget that "everywhere Nature sets her flowers in clouds of refreshing green." —E. S. GARMAN, in "Moore's Rural New Yorker." [Good advice applicable to all countries. The "tropical bed," which may seem unattainable by many in cold districts, or where there are dull and chilly summers, is possible everywhere by the employment and annual cutting down of hardy shrubs and trees with fine foliage, such as Paulownia, Ailantus, Rhus glabra laciniata, Spirea Lindleyana, and many others. The foliage on one year's suckers of these often in the London district proves more "tropical" in aspect than that on tender trees that make one year's growth only.]

LOCUSTS IN SPAIN.

THE "Times" correspondent gives the following startling account of the ravages committed by locusts on vegetation in countries not far from us:—I will give you now in contrast painful enough with the thought of the glorious growing cereal crops, the details of the plague of locusts now threatening Spain. The provinces infested are those of Cartagena, La Mancha, Ciudad Real, Estremadura (Badajoz), Toledo, and Salamanca, by which it will be seen that the plague extends from Cartagena to the north-west, passing south of Madrid, and thence, jutting on the confines of Portugal, northward to Salamanca. The popular account of the locust in Spain is just given to me by a gentleman from Linares, in the province of Jaen, is as follows:—"The locusts have amounted to a plague in Spain for not more than eight or nine years; they perpetrate their race by eggs, for the reception of which they make, with their mandibles, little canutos, or hollow tubes, like kernels of Pine Nuts; in these they deposit the eggs, carefully close them up, and cement them over all so perfectly that they can resist damp. These little tubes they press and fasten into the earth, until hidden. They always choose the hardest earth, and that which, in their belief, will be untouched by the plough. They lay the eggs in August and September, and these lie in earth until April, when they begin to develop. The popular fallacy in Spain is that every egg takes five years to hatch. The eggs are so small that they cannot be counted, but each canuto, or case, contains upwards of 100 eggs. When the egg first develops itself, it is called an estado de mosquito, which shows that its size is insignificant, and like a young mosquito. When fully developed the langosta has four wings, the two inside not serving for flight; it has six feet, two of which are longer than the rest, and furnished, for springing, with a saw of sharp points. The length of the locust in Spain varies from one to four pulgados (a pulgado is equal to 1 in., or rather less). The plans in vogue for destroying these animals are (1) to sweep them, with huge brooms and branches of trees into large bags called 'btronos,' and then bury them in deep pits; (2) to open

trenches transversely in their line of march, and to fill them in with earth when the insects are within them. But all operations against the locust must be performed in the first and earliest stage of its development." The province of Jaen, bordering on La Mancha, is at times, and slightly so now, infested with locusts. The plague of locusts threatens to assume serious proportions. Although rain has fallen heavily in Seville and Cadix provinces, yet the drought has been great in the West Midland districts. Now is the one and only moment at which to extirpate these pests, as they are in their first stage of development, as yet unhatched fully by the sun. Once let the full force of the spring sun smile on them, and these myriad hosts will start into life, and "make the Garden of Eden a desolate wilderness." So quickly does heat hatch them that if you place a can of eggs in your pocket, the heat from the body will bring them all into life in twelve hours. The following orders and telegrams from the Madrid papers will give some idea of the extent of the mischief anticipated. On March 28 appears this:—"Royal Order.—All commanders of garrisons to spare all the troops possible to aid in extirpating the locusts." On April 1, "The locust has appeared in the province of Cadiz, near Medina-Sidonia." On April 5, "The locust threatens to destroy all the cereal crops of Salamanca province." On April 5, "The 1000 troops sent to Badajoz (Estremadura) are not enough; we need at least 4000 soldiers." On April 7, a Royal decree voting 500,000 pence for the extinction of the locusts and commanding all Town Councils to pay to the soldiers engaged in the work as follows:—To each private 5d. daily, each corporal, 7d., and each sergeant 10d., in addition to their ordinary pay. On April 8 General Primo de Riviera proposed to Government to use the German method of digging trenches and turning in herds of pigs to eat the locusts. On the same day Senor Mariscal, a deputy, proposed a second, and Senor Seco de Lucena a third way of extirpating these pests—namely, by asphyxia. Earnestly we all hope that the exertions of the Government—and well and promptly has it bestirred itself on this occasion—in sending troops to the infested provinces will prevent the destruction of the growing cereal crops. These flying herds eat every green thing, except the leaf and fruit of the Red Tomato, and so great are their numbers that, only two years ago a train was stopped in the province of La Mancha or Ciudad Real by masses of these insects piled up, like driven snow, along and upon the line.

Centigrade and Fahrenheit.—The Centigrade thermometer scale is now becoming so frequently used in English books that a short method of turning incomprehensible Centigrade into intelligible Fahrenheit will be a desideratum. The rule is simple, and the operation, after a little practice, may be performed mentally. All one has to do is to double the Centigrade number, take a tenth away from it, and add 32 to the number obtained. Let us take 60° Centigrade. Twice 60 is 120, take one-tenth away, i.e. 12, and 108 remains, which, added to 32, makes 140, which is the answer. Taking a more difficult number, 32 Centigrade, we double and obtain 64, from which we take 6.4, leaving 57.6, to which we add 32, the total being 89.6.

A Tree Protector.—A correspondent of one of the morning papers remarks that Coburg is famous for old shady trees. These are to be seen, not alone on the borders of the city and marketing the highway, but they dot, either singly or in groups, the fertile fields and fruitful meadows in every direction, attracting the eye and adding greatly to the beauty of the landscape. One might naturally infer that the people have a greater love for Nature's charms than is commonly the case, or this fine timber would long since have been turned into money. But these sylvan ornaments are preserved through the wise forethought and liberality of the deceased father of the reigning Duke. The old ruler of the Duchy was fond of trees, and whenever he saw a group or a single one that ought to be spared as a "thing of beauty," he took measures to make the same a "joy for ever" by purchasing the fee-simple outright from the owner. Therefore there are many grand old monarchs of the forest existing, either as monuments of his loving care or else enjoying for their lifetime a pension from his bounty.

Window Plants in Norway.—To see plants in windows in perfection, the northern parts of Norway, such as the towns of Molde and Trondhjem, should be visited early in the summer. The people have a passionate love for flowers, and tend those in their houses almost as if they were children. In some places I have seen miniature rakes with ivory backs for breaking-up the top of the soil in the pots, and all the other little cultural accessories are equally perfect. Then, the plants have no coal-smoke with which to contend, and they stand on inside window-sills, fully exposed to the cheering effects of almost perpetual sun-light—not that the sun always shines on them, but his rays are almost always vivifying the air. There is no night during

summer in the latitude of which I speak. Carpets are also taken up when the warm weather sets in, so that the plants have no dust from which to suffer. Certainly I never saw more beautiful flowers at any horticultural show than those to be seen in Norwegian windows. The kinds grown are our ordinary greenhouse plants and a few Roses.—P.

Tea Roses near London.—Tea Roses are so much more at home in mild and sea-shore districts that it is far from common to see them well grown in open beds in London or midland gardens. It is, therefore, worthy of note that there are in the gardens at Gunnersbury many large beds of the finest Tea Roses, mostly one kind in a bed, and they thrive admirably. It is, however, difficult to keep them through the winter without suffering, and blanks have to be filled up in spring in the case of the more tender kinds. This trouble is, however, well repaid by the abundant and long-continued supplies of flower. The Roses are pegged down, so that in summer and autumn they quite cover the beds.—R.

Primula cortusoides amena for Night Decoration.—In a group of this Primrose, shown at the Aquarium Exhibition last week, the rich tints of the flowers were converted under gaslight to a deep-glowing magenta, that was remarkably effective. As Primroses of this class are easily grown and propagated, this fact is well worthy the attention of decorative florists. Some colours that look gay in the daytime lose all their beauty when subjected to gaslight. Flowers, that range from white through tints of pink, rose, magenta, and red up to crimson, are most effective under artificial light, while yellows and blues are not. The *cortusoides amena* section of Primulas, when well grown, make beautiful exhibition plants, a fact which managers of April shows will do well to bear in mind.—D.

Violets in Pots.—The efforts made to obtain collections of these at the recent show at the Westminster Aquarium was but partially successful, only one kind being exhibited, viz., the Neapolitan. April is too late for single varieties of the Violet—generally the sweetest scented—but there are several fine double kinds that are both sweet, and when well-flowered, very handsome. The Giantess and King of Violets are rich dark blues, the flowers of which are sweet and the plants good in habit. The finest double white is Queen of Violets, a variety that is free, and one which has very large massive blooms. The Neapolitan is a fine showy kind, and closely allied to it, although not quite so robust is the Princess Louise—a variety that flowers freely, and does well in pots. *V. rubra plena* is a fine double red, and makes a good pot variety. Here, therefore, are only half-a-dozen kinds, and even these do not include all the double sorts. A class for six pots of Violets should have, as a condition, that not less than three sorts should be shown. A similar class for single kinds might well be introduced at March shows; as, thanks to Mr. Lee, we have some very fine single kinds that do well in pots, and which are deliciously scented.—A. D.

How Doctors Differ.—In the vegetable kingdom there are several substances that possess the double quality of food and medicine, and as such might be usefully employed in therapeutics. Among the vegetables that possess the valuable property referred to Water Cress may be mentioned. According to an analysis by M. Chatin, Director of the School of Pharmacy of Paris, and present President of the Academy of Medicine, Water Cress contains:—1, a sulpho-nitrogenous essential oil; 2, a bitter extract; 3, iodine; 4, iron; 5, phosphates, water, and some other salts. As medicine the Water Cress has been vaunted for its efficacy in all cases in which the digestive organs are weak, in cachexia, in scurvy, in scrofula and lymphatism; it has even been prescribed as a cure for phthisis. The medicinal principles which it contains are more or less abundant according to the culture or maturity of the plant. Thus when the plant is in flower they are in greater quantity than before that condition; the essential oil increases according to the quantity of the sun's rays to which the plant is subjected. The proper culture of Water Cress develops in it the bitter and tonic principles, and the phosphates will be found in proportion to the manure employed. Finally, the quantity of iron will depend upon the richness of the water in which the cress is planted. As food Water Cress ought to be used in its green or uncooked state, in the form of salad or without any seasoning. Water Cress enters largely into the composition of the "sirop antiscorbutique" of the French Pharmacopoeia.—"British Medical Journal." [Some time ago we published a paragraph in which it was stated that so high an authority as Sir Benjamin Brodie thought Water Cress unwholesome.]

Dr. ENGELMANN'S notes on Agave will be found in the "Transactions of the Academy of Sciences of St. Louis, Missouri," for Dec., 1875. The memoir contains a systematic enumeration of the North American species, in which several novelties are now first described.

NOTES OF THE WEEK.

— THE lately-introduced Official Rhubarb (*Rheum officinale*) would seem, from the vigorous way in which it is coming up at Kew, to be of some merit as a hardy fine-leaved plant, as, indeed, are most of its family. It, however, seems exceptionally early in producing large bouquets of ample leaves.

— THE finest of the large-leaved Saxifrages (*Megasea*) is the deep rosy-purple *Saxifraga purpurascens* now in bloom in the Wellington nurseries. It will form, when grown in pots, a lovely plant for greenhouse decoration, as well as for the rock-garden. It is as yet very seldom seen in good collections.

— THE backward season seems to have a marked effect on the supplies of Asparagus, which, instead of becoming cheaper as is usual as the season advances, have since Easter advanced very considerably in price. This is mainly owing to a check in the very extensive supplies that now come to us from Toulouse and its neighbourhood.

MUCH has of late been said as to the excellence of the St. Michaels Pine-apples, and many have, in consequence of the superior quality of these fruits in winter, thought of giving up Pine-apple culture. It may be as well to state that the St. Michaels supply ceases about the end of the present month, and that there is likely to be as large a demand as ever for English-grown Pine-apples ripening in May and June.

— WE learn from Mr. Arthur Turner that Cox's Orange Pippin has been kept at Slough in perfect condition in a wine cellar up to the present date. It is now a long time since fruits of this variety fit to eat have been seen in our markets. It is very probable we shall have to modify our notions as to construction of fruit rooms. The cellar fruit room is no doubt far better than our raised and very often warm ones.

A BEAUTIFUL wall plant is the Shamrock Pea (*Parochetus communis*); it is a creeping perennial not often seen in cultivation, and very seldom flowers abundantly. If induced to take root on an old wall or one of those "Alpine walls" illustrated in "Alpine Flowers," it thrives better than in any other position, and its delicate shoots hang gracefully down, laden with charming blue Pea-like flowers.—W. J.

MANY of the samples of White Almerian Grapes now in our markets have been preserved throughout the winter in barrels of cork dust. Some samples that we have examined have been in cellars in Covent Garden Market in barrels for nearly seven months, and they turn out with very few damaged berries. This fact is not, we think, of much importance as regards the keeping Grapes in England, as so much depends on the condition of the Almerian Grape when gathered, and the variety seems also a long-keeping one.

THE fine collection of Orchids belonging to Mr. Philbrick, Avenue Road, Regent's Park, is at present particularly showy, many plants being in flower. Most of the varieties of *Phalænopsis* are flowering in quantity; of the lovely *Dendrobium luteiflorum* there are several plants; also the Roman red-lipped snow-white *D. Jamesianum*; and perhaps the finest variety of *D. crassinode* ever seen. *D. thysiflorum*, and a great many other varieties are masses of bloom; and there are also some fine well-bloomed *Saccolabium*s, likewise *Aerides Fieldingii* and *Vandas* in profusion, as well as the rare *Cymbidium eburneum*, and many other plants. In the cool house we found the scarlet-flowered *Ada aurantiaca*, many fine examples of *Odontoglossum Alexanderi*, *O. Pescatorei*, *O. triumphans*, and various *Oncidium*s in full bloom; also the rarer *Masdevallias* throwing up flower-spikes thickly—all marvels of beauty and good culture.

AMONG Orchids now in bloom in Messrs. Veitch's nursery at Chelsea, we may note the new *Cypripedium Druryi*, which looks like a hybrid between *C. Parishii* and *C. villosum*, having solitary greenish flowers, with a dark band down the centre of the sepals and petals. *Cypripedium vexillarium*, a cross between *C. barbatum* and *C. Fairricanum*, also bears a two-flowered spike. Another hybrid, *Lælia flammea*, bears a two-flowered spike of rich orange-sepalled flowers, having a purple lip. It is the result of a cross effected between *L. cinnabarina* and *L. Pilcheri*, and is very beautiful and distinct. Several very large-flowered, well-formed varieties of *Pescatorei's* *Odontoglossum* are in bloom, and many plants of *O. vexillarium* are throwing up strong flower-spikes, while a plant of *O. nævium* bears twenty-four spikes, each bearing from ten to twelve flowers, which are, however, as yet unexpanded. A plant of the larger variety of the last-named species bears nineteen strong spikes, and the choice golden-flowered *Oncidis*, *O. concolor* and *O. Marshallianum* are both represented by several flowering plants. The last-named bears enormous blossoms on a slender branched spike, and as

seen suspended beneath the roof of the house, they look like great golden butterflies. A specimen of the little rosy-flowered *Saccolabium ampullaceum* bears fourteen spikes, and is just now very pretty; it is growing on a Teak-wood raft, with its roots merely surrounded by a little fresh *Sphagnum* Moss.

AMONG cut flowers now in season, perhaps the greatest favourites are those of forced Pinks; of these one of the best is Miss Joliffe, a rosy-salmon variety of free habit; and among white kinds, Lady Blanche is one of the best. Both kinds are largely grown for market, and well repay careful culture.

ONE of the most beautiful Orchids we have for a long time seen is the fine variety of *Odontoglossum roseum*, now in bloom in Lord Lonsborough's collection at Norbiton. It has the colour of an Alpine Phlox, and the grace of flower-stem of the Solomon's Seal, being withal very dwarf and neat in habit.

SOME 200 plants of the new and beautiful *Odontoglossum cirrhosum* are to be sold at Stevens's on Monday next. This fine *Odontoglossum* was described in THE GARDEN for April 8th, p. 348; a plant of it in flower is to be exhibited at the sale; therefore all those present will be enabled to judge for themselves as to its merits.

THERE is considerable variety among the names of the Grape Hyacinths now in flower in our gardens, but very little real distinctness of aspect, especially when seen a few yards off. The most distinct plant of this race that we have seen for some time is that known as *Botryanthus szovitzianus* now in bloom in the Exotic Nursery, Tooting. It is a very beautiful hardy plant.

The single *Kerria*, a rare plant compared with the double kind known well in most gardens, is a shrub of high merit, exceedingly graceful in habit when grown untrained, and very tractable as a wall plant wherever a wall is an aid to its blooming. It bears numerous rich golden flowers, and is a more beautiful plant than the old double kind. There is a plant of it on one of the walls at Kew.

MR. DOUGLAS, Loxford Hall, has sent us a beautiful truss of *Auricula Topsy* (Kay), one of the most distinct and beautiful of all pure selfs, the body colour being of the richest velvety description, and the paste or margin surrounding the eye of the purest white. This variety was one of the most effective at the Aquarium Show the other day, and well deserves the attention of all interested in these charming old-fashioned flowers.

AZALEAS and greenhouse *Rhododendrons* are now very beautiful in the Royal Exotic Nursery, Chelsea, a large specimen of *R. Countess of Haddington* bearing several hundreds of large bell-shaped rosy-white flowers. Among the Azaleas we noted *Crispiflora*, an old but very distinct and effective variety, with frilled petals, and a small plant of Carl Enke, bearing rosy salmon-white edged blossoms.

It was only at the Westminster Aquarium show, the other day, that we saw the true character of Mr. Williams' new *Adiantum gracilimum* fully displayed in a huge specimen shown by Messrs. Standish. So far from the delicately-dissected leaves indicating any feebleness in the plant, the opposite is the case; it is extremely free and vigorous. It is thoroughly a variety of the oldest and most popular of our common stove Ferns (*A. cuneatum*), one of the most valuable Ferns ever introduced to cultivation.

AMONG the many plants forced for the sake of their flowers none are more acceptable than Lilacs, though frequently they are failures in gardens. About 600 bushes of Lilacs are forced every year by Mr. Denning, in Lord Lonsborough's garden, at Norbiton, and of these plants under 2 ft. in height bear many trusses of flowers. The French variety, known as Charles X., is much used for forcing. These Lilacs are grown in pots from year to year, as otherwise it would be impossible to get small plants into such a free-flowering condition.

A Planted Boulevard for London.—Mr. J. Rahles, a member of the St. Pancras Vestry, some time since presented a petition to that local body in favour of planting the Camden Road, three miles in length, as a boulevard. The matter was referred to the Works Committee, who rejected the proposal, but Mr. Rahles determined to test the opinion of the Vestry by putting a notice of motion on the agenda paper to carry out the proposition. This motion came on yesterday, and was carried by a large majority. The matter was then referred to the chief surveyor to draw up agreements and make the necessary arrangements for carrying out the planting. It would be well if in some of these new street plantings in London other trees than the Plane were tried. Various others are suitable, and variety in trees is as desirable in cities as in woods.

THE FLOWER GARDEN.

GENERAL STRACHEY'S SAXIFRAGE.

(SAXIFRAGA STRACHEYI.)

THIS Saxifrage is one of the large-leaved section distinguished by the sub-generic title of *Megasea*; with this section we have long been acquainted in old-fashioned gardens, its most popular representatives being the heart-leaved and broad-leaved kinds called *S. cordifolia* and *S. crassifolia*. The subject of our present illustration was discovered at a considerable altitude on the Himalaya Mountains by Major (now General) Strachey, and constitutes by no means the least in importance of the many interesting plants which he has been the means, not only of discovering, but also of introducing into our gardens. It has now been in cultivation some six years, and when I say so, be it understood I do not mean in general cultivation, for it is still a scarce plant, and to be met with only in botanical gardens and a few very select private collections; doubtless, in time, the fact that it possesses an inherent beauty of its own as a spring-blooming plant, and also a vigorous constitution and free-flowering habit, will render it equally abundant with its Siberian allies, to which I have before alluded. In Strachey's Saxifrage the leaves are developed from a strong and somewhat woody decumbent stem, rendered rough and scaly by the persistent attachment of the stipuleaceous appendages which are developed from the inner side of the petioles, and from which the leaf itself appears to disarticulate after reaching maturity. The leaves are large, similar in size and also in their leathery consistency to those of *S. crassifolia*—nearly as broad as long—the margins slightly notched and ciliated, the colour of the cilia giving a pink outline to the leaf. These are in shape almost orbicular, glabrous, and shiny both above and below, the outline of the principal vein being well marked by depressions on the surface; in colour they are light green. The flowers are arranged in compound or branching cymes, somewhat scorpioid in character; these are supported on stout foot-stalks, which elevate them well above the mass of foliage. The calyx is of a crimson colour; the petals are of a light rosy-salmon tint at the margin, gradually shading into the deeper colour of the calyx-tube, giving the flowers a character specially distinctive from the others with which we are familiar in this section of the genus. As regards the marginal outline of the petals, they are irregularly undulate. Its closest ally is *S. ciliata*, from which it possesses the following well-marked distinctions:—A greater breadth of leaf as compared with the length; a more irregular arrangement of the leaves, which are supported on shorter foot-stalks, the blooming cymes being larger and more floriferous; and the plant as coming from a higher altitude (some 12,000 feet on the Himalayas) being hardier, and quite capable of standing our climate. It blooms in March, and should have in cultivation a special nook allotted to it, sheltered either by shrubs in the border or by protecting masses in the rockery, otherwise, if exposed to the bleak winds with which the mouth of

March is usually and unhappily associated, the plant would soon be shorn of the delicacy and beauty of its blossoms. I have never succeeded in raising seeds of it yet, nor am I aware that others have been more successful; but this I know, that I generally have a goodly number of applicants for the first spare plant I have of it, and hence I infer that its beauty is pretty generally appreciated. JAS. C. NIVEN.

Botanic Gardens, Hull.

GARDEN IVIES, THEIR USES AND CULTIVATION.*

THE Garden Ivies are more useful than any one would imagine, judging by the little attention that is paid to them. Many are the fine old ruins and houses that are rendered verdant and attractive by means of Ivy. It is best known to us as a climber, although it may be grown in a variety of other ways. It will continue to climb as long as it has anything to which it can adhere; but when the summit has been reached, and it has no farther support, its nature seems to change; it ceases to emit its root-like claws, throws out branches horizontally, flowers, and fruits. Its flowering season is September and October; the berries ripen early in spring, and have a very effective appearance, hanging as they do in black clusters. One characteristic belonging to the Ivy is that when growing on a wall or old building, should it get severed from the ground, it will still live supported by its claws, which become veritable roots, adhering firmly to, and feeding on, the substance to which they cling. Can the Ivy be called a parasitical plant? Some say it is, but that is an opinion with which I cannot agree, for if when growing on a living tree it becomes severed from the ground, it may live for a time, but it will not thrive if compelled to live on the bark alone; I have never seen a grand specimen of it on a living tree when cut off from its own roots. Ivy I believe to be hurtful to trees, for when once it obtains the mastery over them, it checks the flow of sap, robs them of light and air, the result being decay. The trees on which it grows best are the Oak and the Elm. In the grounds of Wimbledon House there is a fine old Pollard Oak almost entirely covered with Ivy, with which the tree has been killed. Some affirm that Ivy

is injurious to buildings; such may be the case where in the course of years its root-like claws have penetrated the brickwork, as for instance, at Arundel Castle, which has been threatened with destruction owing to the inroads made on the walls by the Ivy with which they were, until recently, covered.

The uses to which Ivy may be put are numerous; in addition to its being one of the best plants for covering walls and palings, it has a good effect in pots under glass in winter; edgings for beds may be made of it, and nothing is more useful for covering the ground under trees. If plunged in beds in pots, with a piece of crock under them to keep out worms, it looks well in winter mixed with Yews or Hollies, when many shrubs are bare and leafless. Ivy may be propagated by

* Read by Mr. Alderman at the March meeting of the Wimbledon Gardeners' Improvement Society.

General Strachey's Saxifrage.

means of seeds, cuttings, layers, and grafts. When the seeds are thoroughly ripe, gather them and sow them thickly on a bed of sandy soil, and keep the ground clear of weeds; when of sufficient size, plant them in rows in a nursery bed, and after they are strong enough, plant them out where they may be required. Variegated kinds rarely come true from seed, but they may be propagated by taking off young shoots 4 in. long, with some green in their leaves and inserting them in sandy soil under a hand-glass. Cuttings may be quickly struck by taking off young shoots from a wall to which they have attached themselves by their fleshy claws, and inserting them in pots or in the ground; if this be done in June or July they seldom fail to root. Long shoots may also be pegged down on any damp soil in the form of layers; they root quickly in old Cocoa-nut refuse. Ivy may also be increased as follows:—In July get some long cuttings, and, instead of putting them upright in pots, peg them firmly down all round on the soil; these will root at every joint, and as many plants can be made of them as may be desirable. Ivy may also be grafted with success. It will grow in any soil in the open ground, but for pots it requires good loam, manure, and leaf-mould, especially if desired to remain in the pots for any time. The large green-leaved and free-growing varieties thrive in a moist rich soil, but variegated kinds require material of a poorer character so as to retain their bright colours; if too richly fed they are liable to become green. If good variegated specimens be required, the soil most suitable for them is a light loam, mixed with brick rubbish. They should be treated as a matter of course in all respects as hardy plants, and be freely exposed to the weather. Different aspects give different colours; some of the dark deep shades are obtained by exposure on a damp north wall, while the richer blotches are better when fully exposed, but in all cases shelter and shade promote free growth and bring out the rich green hues. The best Ivies for walls are the fast-growing large-leaved kinds, viz., *Hedera canariensis*, *algeriensis*, and *Rægnieriana*; the common English *Hedera Helix* looks neat and clings close, but grows much more slowly. The variegated kinds look well on walls also. When a wall is desired to be covered with Ivy, strong vigorous subjects should be obtained, and the ground forked up; plant them in April, giving them frequent attention in watering and nailing, until they attach themselves, when they will only require periodical examinations for the falling away of a few stray shoots. After the Ivy is thoroughly established it should be examined each year in March, and all leaves and laterals cut back to the stem, which operation will give the Ivy a bare appearance for a time, but it will afterwards push forward its leaves and have a neat and pleasing appearance during the remainder of the season.

Ivy may be grown in a variety of forms, such as standards, bushes, pyramids, and umbrellas.

The vigorous green-leaved kinds make good standards. Strike the cuttings in pots in July and August, and keep them in a cold frame during winter; in April pick out those with straight leaders, and plant them out in well-manured loamy soil, keeping them trained to stakes, and in July pinch the side-shoots into two or three leaves; the next season cut the leaders back to the height required for the standard; let side-growths of the head push forward, and train them out so as to keep vigour in them, but pinch the side-shoots in so as not to let them take the lead, and the following season cut the leaders back to two or three buds. Follow this treatment for about four years, and good specimens fit to be planted in borders for ornament will assuredly be obtained; after they are in the borders, remove the side-shoots from the stem a few at a time, beginning at the bottom; the result will be a clean stem, and the head can be trained to any desired shape, or it may be left to grow at its will.

Pyramids are the easiest forms in which to train Ivies in pots. Take the young shoots upright by inserting a few stakes in the pots; let the soil be good loam and rotten manure, twine the side-shoots round the stakes, which will soon be furnished; in the autumn, after growth is finished, tie the stakes firmly together at the top; if the Ivies have grown freely, they will be of sufficient size to be effective, and may be kept in the same pots several years if during the summer the pots be plunged in rotten leaves or Cocoa-nut fibre refuse, and

kept well watered; plants so treated make good specimens either for flower-beds or conservatory during winter.

Umbrellas may be formed by taking a shoot straight up, and training it out on a head of wirework, until the outline is covered; then pinch the side-shoots in, so as to form the head into a dense mass of foliage. The side-shoots from the stem must afterwards be removed, as previously stated. This style is useful in house decoration.

Bushes can be grown in pots of either the climbing or fruiting varieties. I have seen the yellow-berried variety (*H. chryso-carpa*) look beautiful in winter, with its bright berries and green foliage. It takes a long time to grow good bush specimens; they should never be pruned unless a strong shoot push out beyond the rest; in all respects they require the same treatment as the others. All fruiting varieties are useful in making bushes in pots for plunging in the flower garden during winter.

The following are some of the varieties with which I am acquainted, and they consist of the smallest and largest-leaved kinds in cultivation:—*H. canariensis*, *algeriensis*, *Rægnieriana*, *dentata*, *digitata*, *digitata nova*, *taurica*, *Donnerailensis* (*minima*) *maculata*, *elegantissima*, *sagittæfolia*, and *chrysocarpa*.

GARDEN VEGETATION IN MARCH.

By JAMES MNAB, Royal Botanic Garden, Edinburgh.

DURING March we had a good deal of snow, rain, and wind, with frequent frosts, which proved a great hindrance to vegetation and an impediment to the performance of all out-of-door work. On twenty-one mornings the thermometer stood at or below the freezing point, indicating collectively 98° the lowest markings being on the 13th, 16th, 17th, 19th, 20th, and 21st, when 23°, 25°, 24°, 25°, 23°, and 20°, were respectively indicated. The highest morning temperatures occurred on the 1st, 2nd, 3rd, 4th, 6th, and 30th, when 38°, 36°, 37°, 38°, 37°, and 38° were indicated, all being below the temperatures of January. During March, 1875, the thermometer was ten times at or below the freezing point, indicating in all 45° degrees of frost. The following Table shows the amount of frost that occurred during the months of March for the last thirteen years:—

1864	71°	1868	29°	1871	25°	1874	37°
1865	59°	1869	57°	1872	25°	1875	45°
1866	66°	1870	50°	1873	25°	1876	98°
1867	77°						

Herbaceous plants this year are rather behind the average as regards progress, and those which have flowered are far from being in a satisfactory condition, both February and March being much against them. The following is a list of spring plants, the dates of flowering of which are annually reported:—

	1876.	1875.
<i>Scilla bifolia major</i>	March 2	March 14
<i>Arabis albidia</i>	" 5	Feb. 10
<i>Tussilago alba</i>	" 8	" 15
<i>Mandragora officinalis</i>	" 12	" 28
<i>Iris reticulata</i>	" 13	March 19
<i>Symphytum caucasicum</i>	" 15	" 31
<i>Narcissus pumilus</i>	" 15	" 13
<i>Scilla bifolia alba</i>	" 15	" 17
<i>Tussilago nivea</i>	" 18	" 6
<i>Muscari botryoides</i>	" 18	" 26
<i>Corydalis solida</i>	" 25	" 23
<i>Symplocarpon foetidum</i>	" 25	" 30
<i>Erythronium Dens canis</i>	" 28	" 21
<i>Ribes sanguineum</i>	" 30	" 30

In the rock garden seventy-four species were counted in flower on the 31st of March; among them the most conspicuous were *Iris reticulata*, *Scilla sibirica*, *S. bifolia*, *S. b. major*, *S. b. alba*, *Sisyrinchium grandiflorum album*, *Gagea lutea*, *Helleborus argutifolius*, *Hepatica angulosa*, and all the varieties of *Hepatica triloba*; also, the varieties of *Saxifraga oppositifolia*, *Aubrieta grandiflora*, *Primula vulgaris rubra* *P. purpurea*, *P. denticulata*, *P. nivalis*, and *P. viscosa*, *Draba aizoides*, *Dondia Epipactis*, *Andromeda floribunda*, *Erica hybernica spicata*, *E. herbacea alba*, and *Epigæa repens*. Up to the end of March no perceptible difference was noticed in the arborescent vegetation in the garden from what was observed at the end of January. Perhaps the most remarkable feature observed was that of certain Coniferous plants,

which assume a brown hue during the late autumnal months, remaining in that condition all the winter, and which, as the season advances, pass into green, and finally into the golden tint peculiar to them, and which they retain during the summer months. In my report up to the 31st of January, I stated that, owing to the unusual mildness of that month, *Thuja aurea*, *T. elegantissima*, and others, had parted with their brown winter hue, and that they were, on the 31st of January, perfectly green. Since then the backward state of the weather, together with a series of low temperatures, has been the means of partially bringing back the brown tint, but not to the extent observed during the early winter months; still, a very perceptible brown hue is visible on each of them. It is now evident that many plants have suffered severely during the long and very changeable winter which we have had, particularly species belonging to the Natural Orders Cruciferae and Caryophyllaceae. It is somewhat remarkable that during the last three months we have had the thermometer on fifty-two mornings at and below the freezing-point, indicating altogether 314°; but, notwithstanding this low average, no ice at any one time has been seen at Edinburgh sufficiently strong for skating or curling purposes, nor yet have any of the frosts been sufficiently severe to reach the small vermin now in the ground, not even slugs, which at the present time are particularly numerous and destructive.

WARE'S SHELTER PANS.

IN Mr. Ware's nurseries at Tottenham, where great numbers of choice young hardy plants are put out at all seasons, a shelter pan or pot, of which the wood-cut here given is a section, is found very

Section of Shelter Pan.

useful. It is simply a low pot without a bottom, measuring about 8 in. across. When young plants of any particular value are first placed in the open air in spring, one of these is often placed over, or rather around it, and those who know how often young plants are killed or injured from various causes will easily understand how useful such contrivances are. They shelter the young plant from cutting or high winds from any quarter; they turn aside the browsing slug or snail. They may be so placed as to give a partial shade; and they protect the plants when a complete shade or protection is thrown over them. Such shelters also preserve a warmer atmosphere round the young plant than when it is fully exposed. When the plants are established and fine weather has set in, these contrivances are easily removed. The shelter pan is merely placed on the ground, not sunk in it. V.

Roses on Briers, and on their own Roots.—Where Brier stocks are used, young straight-stemmed ones, green and well-rooted from the hedge-rows, about two years old, are best, not those having heavy roots like a club. It is somewhat difficult to get the kind of Briers here alluded to, but they may be obtained by paying a little more money for them. He who confines himself to growing only standard and half standard Rose trees, must either bud them himself, or be under the necessity of buying them from the nurseryman, in order to fill up spaces made in winter by frost. Roses on the *Manetti*, when planted about 3 in. below the worked part, become rooted at the junction after having been planted about two years. After that they may be lifted and examined, when those that have formed roots may be operated upon as follows:—Let the *Manetti* root be cut off just below the junction with the scion with a pair of shears called guillotines, and the Rose (now upon its own roots) should be re-planted somewhat deeper than before. Roses thus treated may be taken up again in a year or two, and split up into three or four good fibre-rooted Rose trees. Roses on the *Manetti* also submit well to layering.

It is not wise to plant standard Roses in town gardens, as they generally die after the first year, or at best have only a sickly appearance. Roses on the *Manetti* are better than those on their own roots for town growth. The *Manetti* stock succeeds well even on poor soil. Roses on their own roots may be grown with advantage in the country, where the soil is naturally rich and good, but where the soil is sandy or gravelly Roses on the *Manetti* will be found to be the best. Liquid manure-water should be applied to them twice a week, from April to the end of September.—HENRY TAYLOR, *Fencote, Dedale*.

Self-sown Portulacae.—Few annuals are more beautiful than these, yet, with the exception of a patch or two in the mixed border, one seldom sees them. They should occupy a situation fully exposed to the sun. Here we always have one large bed of them, which never fails to obtain a large share of admiration; and this requires less attention than any bed in the garden. About the middle of April, when the soil is dry, I skim off about an inch of the surface, which I run through a sieve; then I manure and dig the bed, spreading a little of the sifted soil evenly over its surface, and the result is, by the end of May, a good regular bed of plants. This is done every year, as, besides the necessity of manuring and digging, if left to themselves they come up far too thickly, and consequently weakly. The surplus sifted soil may be used for other beds; it is always so full of seed that a small quantity of it is sufficient for a bed. If I were forming a bed for the first time, I should procure a packet of seed, and after thoroughly mixing it with some dry earth sprinkle it evenly over the surface at the time and in the manner above described. I find this to be more satisfactory than raising seedlings in a frame and transplanting them. They come into flower as early as the other bedding plants, and last the whole season. They succeed best in a light sandy loam, and require but little water.—D. UPHILL, *Moreton, Dorchester*.

The Twining Hyacinth (*Brodiaea californica*).—Of all the pretty flowers that abound in California we know of nothing prettier than the Twining Hyacinth. The flowers are of a very fine pink or deep rose. It grows in the mountains and twines over every bush it can reach, and the flower-stem goes to the top of the bush to which it is attached, no matter if it be 5 ft. or 10 ft. in height. After it gets to the top of the bush and rests awhile to be sure it has got a good hold, it quits the ground, and goes on blooming and seeding for weeks and months, regardless of the burning sun by day or the cool mountain air by night. The leaves are long, narrow, and grass-like. The roots go very deep, and being entangled with the other roots, it is next to impossible to get them up. This plant is in flower at all times from May to September. The flower-stem breaks off near the ground, and the earth or flowers are left swinging in the air without any connection with the root or root, supported by the bush about which it twines.—JAMES VICK.

Staging Cut Roses.—The superb baskets of cut Roses shown by Mr. George Paul at the recent Aquarium Exhibition affords to managers of those shows an idea well worth of attention. If it were possible to introduce a class for twelve varieties, consisting of twelve cut blooms of each, to be shown in shallow baskets set in a bank of Moss or Lycopodium, they would constitute the charm of the exhibition. Several advantages would result from this mode of staging Roses: first, the effect would be much more pleasing than it now is, and there would be an entire absence of formality; second, only the best sorts would be shown in such a class; and thirdly, such an arrangement would prove a much better guide to buyers as to what kinds to purchase and what to avoid than the numberless single blooms of diverse sorts generally shown. Managers of Rose shows have, or should have, two distinct objects in view; first, to encourage the growth of the very best varieties in their respective localities; and secondly, to secure the most effective and beautiful display. That all the finest Roses grown find their way to Rose shows there can be little doubt, but sorts of high-class quality often receive comparatively little notice when represented only by single blooms in a large collection. The invariable monotony attendant on a large show of cut Roses is constantly being deplored, and visitors, instead of being struck with the beauty of individual kinds, pass along the lines of boxes almost with indifference, simply because the exhibition is but a stereotyped repetition of what they have seen before; indeed, it is not unfair criticism to say that barrenness of originality in arrangement is nowhere more evident than in Rose shows. The interest taken in Mr. Wm. Paul's Rose parterre, shown at the Regent's Park exhibition last summer, indicated how readily frequenters of flower shows appreciate any breaking through stereotyped methods of arrangement; and, although it is by no means advisable that the exhibition tables of Rose shows should be converted into floral parterres, in which the flowers should be overlooked in admiration of the design, still it is both obvious and desirable that some more pleasing form of staging should be intro-

need, by which visitors would be more effectually attracted, and the merits of fine Roses more fully displayed. Classes of the kind just indicated could easily be managed by large growers; and for smaller growers classes for six kinds or for twelve kinds, six flowers each might well be introduced. These classes should, however, in the first instance, be adopted as experimental and supplementary, rather than for the purpose of at once effecting a complete revolution. Exhibitors might, perchance, object to them as involving too much trouble; but good prizes would be certain to induce competitors, and if the public appreciated the change, the experiment would doubtless lead to permanent improvement.—A. D.

Mossy Saxifrages as "Carpet" Plants.—I am glad that Mr. Perry (see p. 352) has directed attention to the use of Mossy Saxifrages for this purpose. Early last year we planted *Saxifraga nervosa* as a carpet over a bed in which had been planted *Scilla amœna* and *Scilla italica*, and several of the North American Scillas. The effect was not only pretty, but the ground was kept moist, which suited both Scillas and Lilies. In another bed we had a variety of Mossy Saxifrages covering the ground; in them were planted Snowdrops, Snowflakes, and *Scilla sibirica*, while a number of Primroses seeded themselves into them. This has been a popular bed with all visitors. Since then we have planted large beds of Lilies, with *Saxifraga atropurpurea*, *S. pulchella*, *crispata*, and *densa*, and on the rockwork tufts of *Leucopogon æstivum* and *vernum*, with *S. nervosa*; this makes a pretty green carpet. We have surfaced Lily pots in the orchard house with *S. palmata*, now in bloom, and Lilies in a large bed with *S. nervosa*, and believe the Lilies will be the better for it.—G. F. WILSON, *Heatherbank, Weybridge Heath.*

Alpine Auriculas.—Few spring flowers are more effective than these; they bloom in April and May, and are easily managed. Procure a packet of seed, raise it carefully, and some fine flowers will be the result. A few shallow pans or flower pots half full of crocks should be filled with fine soil, consisting chiefly of loam from rotted turf, leaf-mould, and peat, or a fine sprinkling of silver sand. Press the soil firmly in the pots and soak it well with boiling water, in order to kill any small insects or their eggs that may exist in it. When cold sprinkle the seed on the surface, and cover it very slightly with fine mould. Lay a cover of Moss on the top of each pot to retain the moisture, and place them in a cold frame. Lift up the Moss about once a week, and if the soil appears to be getting dry, which it never ought to be, pour some water on the Moss, an operation which will not disturb the seeds. In about a month the young seedlings will begin to appear. When large enough to handle, pot them off singly into very small pots, using the fine compost already mentioned; they will soon begin to grow in earnest and require a larger pot. They must not be exposed to a scorching sun; the pots should now be plunged in ashes in a situation having a north aspect. Some of the strongest seedlings will show bloom in the autumn, and as soon as the trusses appear, they should be nipped clean out. When a bed has been prepared in October, by digging into it some good rotten hot-bed manure, the plants may be turned out of their pots into it, about 8 in. apart. When the seedlings show their spring bloom, mark those that are good as to colour and quality. Propagate the best by means of off-sets, and get rid of the others by giving them to some neighbouring cottager, who will be glad of them. Alpine Auriculas are very hardy, and as the foliage is not mealy like that of the show varieties, they form desirable plants for window culture, and require only to be secured from damp and drought, to bloom freely and finely with but very little trouble.—HENRY TAYLOR.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

The Spring Phlox (*Phlox verna*).—You name this among desirable spring flowers. It is a most beautiful plant where it does well, but it is rather capricious. I should like, however, to know the authority for the name. I believe *Phlox verna* to be only a nurseryman's name; its proper botanical name is *Phlox reptans*.—H. N. ELLACOMBE, *Bilton Vicarage.*

Destruction of Primrose Blossoms.—Some (to us) unknown enemy entirely destroys the beauty of all plants of the Primrose kind in our shrubbery borders. The ground round each plant is, every morning, strewn with the blossoms and buds which have been cropped off during the night. The leaves appear quite unharmed. Can any of your correspondents throw any light on the matter?—ESSEX.

The Blue Bitter Vetch (*Orobus cyanus*).—This is a compact plant, resembling the well-known *O. vernus*, but dwarfier, and with broader leaves; it produces short racemes of large azure-blue flowers, which are raised well above the foliage, and hence more conspicuous than those of the well-known species just alluded to. It is rarely met with in cultivation, nor can I find it in any of our lists; but it is perfectly distinct, and worthy of being more generally known and cultivated than it is.—J. C. NIXON, *Botanic Gardens, Zulul.*

HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

HARDLY for the hardy flowers, as we call our Alpine and herbaceous friends, they are not so rash as the Plums and Pears in the orchards; otherwise, we might have now to record that the ground was strewn with their ruins after the Arctic weather of last week, which did so much harm to the young leaves and flowers in the orchards round London. Most of the flowers are yet waiting for more genial days, though there are some which do not cease to grow, and show their flowers rapidly, as, for example, the beautiful white Wood Lily (*Trillium grandiflorum*), which is opening its delicate-looking blossoms round London. In London gardens or nurseries, however, it is never seen in the robust state to which it attains in some country gardens, where it is allowed to become established in some shady rich border. Then it is indeed lovely. The finest plants of it we have seen either in Europe or America were at Biddulph Grange, and they were superbly grown tufts about 2 ft. high. Another singular-looking and pretty native of the woods of North America is the twin-leaf (*Jeffersonia diphylla*), with delicate white blossoms reminding one of those of the Bloodroot. Our bare borders and beds are not the places for such plants as these, where they are exposed to relentless easterly winds and the glare of the spring sun. They enjoy the sun most when he shines on them through a light green curtain of leaves overhead, and they do not much fear easterly breezes if accompanied by Mosses or Grass leaves, or Fern fronds, or the many plants that compose the turf and undergrowth of woody places. At Kew some of the beautiful Androsaces are in flower—haunters of the high rocks—never likely to be seen in perfection except in the hands of those who understand Alpine flowers well, or where the conditions are very favourable. The three-leaved Coptis (*C. trifoliata*), the drooping and quaintly elegant *Uvularia grandiflora*, the faint blue Daisy (*Bellis rotundifolia cœrulescens*), the Rouen Violet (*Viola Rothomagensis*), the American Striped Violet (*V. cucullata*), the Cortusa-like Primrose (*P. cortusoides*), are in flower at Kew, where, although the soil is light and warm, the herbaceous department is yet very bare of bloom. That charming little stone-clothing Sandwort (*Arenaria balearica*) is opening its small white stars, accompanied by the Snowy-white Hutchinsia (*H. alpina*), and the little white and rich yellow Whitlow Grasses (*Draba*), of which the creeping Whitlow Grass (*D. repens*) is a good yellow kind, worthy of a place in a choice collection of Alpine flowers. With these in flower are some of the most ornamental of the Alpine Saxifrages, *S. Rochelliana*, *S. aretioides*, and others. The hardy and most precious evergreen Candy-tuft (*Iberis*) are, on the warmer soils, turning from dull green to snow, and the well-known Golden Tuft (*Alyssum saxatile* and varieties) is, as yet, only sprinkled with gold. The Peacock Windflower (*Anemone pavonina*) is in bloom, as is the odd-looking half-ornamental *Allium paradoxum*, the *Gentiana* (*Gentiana acaulis*), the White Potentilla (*P. alba*), and the Soury Grass (*Cochlearia officinalis*). The Caucasian Comfrey (*Symphytum caucasicum*) is unfolding very slowly its blue bells, the spotted Dead Nettle (*Lamium maculatum*), the earlier forms of the Poet's Narcissus (*N. poeticus*), and the neat little Milkwort (*Polygala Chamæbuxus*), begin to enliven the scene, and the Italian Scilla, mentioned last week, is now joined by the Star-flowered Scilla, *S. amœna*.

HARDY FLOWERS AND ENGLISH NAMES.

ONE of the greatest boons to readers of THE GARDEN has been conferred by the newly-adopted plan of illustrating "Hardy Flowers of the Week," and an additional benefit is derived by ninety-nine persons out of a hundred through having plain English names appended to the plants. There are thousands of individuals devoted to flowers who cannot remember names which do not convey a single idea to their minds, and many more hardy flowers would be cultivated if an intelligible name were associated with the recommendation to plant or sow them; for instance, how many would remember to ask for the Snake's Head who would entirely lose all recollection of the *Fritillaria meleagris*; the Crimean Iris would never be forgotten, but the *I. pumila* would have little chance of remembrance. The White Buttercup presents a picture to the mind's eye, but the *Ranunculus alexicalis* falls on the ear without the slightest effect. I am

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

most anxious to know where a supply can be obtained at a moderate cost of bulbs and other hardy outdoor flowers and plants, and also of hardy flowering climbers for trees or walls, which were once common in gardens, and are now almost extinct, but are being happily revived. The general cost of the commonest flowers is so great that many who have extensive grounds and small incomes, but every desire to fill their borders with flowers, know not how to begin for want of material; and, in many cases, seeds are so long before they come to sufficient maturity to flower with any effect, such as Polyanthuses and all the Primrose family, that great discouragement is occasioned, and where there are not hands enough to bestow great labour on weeding and protecting, &c., the seedlings are lost almost as soon as they appear; whereas, if established plants could be procured, they would be preserved and left to seed themselves. It is to be hoped that many nursery grounds may now be, to some extent, devoted to the culture of such flowers, to afford a supply for the million, as well as for the preservation and extensive propagation of the old, well-known, hardy Bush Roses (single and double); among the former of these some of the old, beautiful crimson, small single-flowered Roses are almost extinct, and the old-fashioned Honeysuckles—so fragrant and beautiful in the month of May, in summer, and in autumn—are seldom seen and almost unknown in nurseries. As for the "wild garden," the writer has within reach, in their season, wild Orchises (lilac and purple), Cowslips, Lady's Smocks, Daisies, Blue Veronica, Ground Ivy, Wood Anemone, and Buttercups, viz., the little yellow variety with a horse-shoe leaf that grows on damp ground and on moist hedge-banks, also wild Pimpernels, and the commonly called Buttercup, which flowers amongst grass before the hay harvest. These wild flowers, when once out of bloom, are scarcely to be seen until the spring returns again. Can any of your readers say if there is any practicable method of taking them up when in bloom without killing them, for the purpose of cultivation, in large quantities, as garden plants; or when should I transplant them?—L. C.

THE FRUIT GARDEN.

REPORT ON RED AND WHITE CURRANTS FRUITED AT CHISWICK IN 1875.

THERE is, perhaps, no class of fruits in ordinary cultivation in this country in which so much confusion exists in regard to their nomenclature or their distinctive merits as in that of Currants. Names exist in plentiful variety, but the fruits of all the kinds are very similar, so that it has been impossible to distinguish them. The varieties may vary to some extent as to the size of the bunches, berries, their colour, cropping qualities, &c.; but as these are considerably affected by cultivation, situation, &c., their comparative and distinctive merits can only be ascertained when all the varieties are grown together under the same conditions, as in the present instance. The collection, consisting of forty-five reputed distinct varieties, was got together from various quarters, and represents most of the names to be met with in English nurseries and a few of the French. Altogether there exist about sixty distinct names as applied to the Red Currants, and about fifteen to the White, so that the remainder have to be collected and described. The classification is based chiefly on the appearance of the plants, their foliage, habit of growth, &c. This is very decided, distinct, and easily to be recognised. The typical names adopted may not in every instance be correct, but the varieties given as synonyms are all identical the one with the other as they have been received by the Society. There is no means of distinguishing any of the varieties by their fruit alone.

Reds.

1. **Red Dutch** (synonyms—Fertile, Fertile d'Angleterre, Fertile de Palluan, Fertile de Bertin, La Hative, Hative de Bertin, Bertin No. 9, Belle de St. Gilles, Chenonceaux, Grosse Rouge de Boulogne, Queen Victoria, Red Grape).—This is one of the best varieties in cultivation. A most abundant bearer, and ripening early. The bunches are long, and the berries large, full, and juicy, of a bright red colour. The plant is of a dwarf and somewhat slender habit of growth, never attaining a large size. The leaves broad and flat, deep green, having a sort of metallic glaucous hue, which renders it in appearance quite distinct. The synonyms here given are all referable to this one variety, and which is the one generally grown and known in this country as the Red Dutch.

2. **Knight's Large Red** (synonym—Knight's Sweet Red, Goliath, Fielder's Red, Palmer's Late Red, Pitmaston Red, Pitmaston Prolific, Large Sweet Red, Bertin No. 1, Dancer's Selected).—This variety is not quite so early as the Red Dutch. It is a most abundant bearer. The bunches are long and produced in immense

clusters; berries of medium size, of a bright red colour. The plant is of strong and vigorous growth, the shoots growing mostly erect. Leaves pale green, rather small, somewhat deeply cut and crumpled in appearance. This variety is in most general cultivation in the market gardens around London, having probably been selected for its strong, vigorous constitution. Messrs. Krelage, of Haarlem, sent fruiting branches of this variety as the true Red Dutch Currant as grown in Holland.

3. **Old Red** (synonym—Rouge Commune).—This greatly resembles the preceding. The plant is of most robust growth, but a poor cropper and with small berries. It is most probably the original stock from which Knight's Large Red, the present common variety, has been selected.

4. **Red Cherry** (synonym—La Versailleise).—The berries of this variety are very large and handsome, almost like small Cherries; but they are produced very sparingly, the bunches frequently consisting of only one berry, and from twenty to thirty berries on a plant. The plant is of a gross spreading habit of growth; the shoots pale, very gross; leaves very large, broad, deep green. It is unsuited for cultivation in the open ground, as the shoots, from their gross nature, break off so easily, and so no plant is formed. The buds do not break freely after pruning. Grown against a wall it is more satisfactory.

5. **Houghton Seedling** (synonyms—Houghton Castle, Orange-field).—This is a late variety. The berries of medium size, deep red, and rather acid; bunches long, produced in very thick clusters. A most abundant cropper. The plant is of a very robust, close-growing, sturdy, stubby habit, very rarely producing long shoots. The leaves are small, deep dark green, somewhat deeply cut and crumpled in appearance. Very distinct. This variety, from its close compact habit of growth and sturdy constitution, is very suitable for growing in exposed situations and for training as an espalier or pyramid.

6. **Gondouin** (synonyms—Raby Castle, May's Victoria, Imperiale Rouge d'Holland à grappes longues).—This is a remarkably strong-growing late variety. The bunches are very long. Berries large or above medium, of a bright red colour, with a sharp acidity. As a bearer it is only medium. The plant is of a most robust growth, soon forming large bushes. Shoots strong reddish. Leaves large, dark green, with reddish veins; flat, deeply cut, very showy, and very distinct. The flowers have also a reddish tinge. This is one of the latest Currants to ripen and hang well on the plants afterwards. The plant, from its strong vigorous growth, is very suitable for growing as standards or large bushes.

7. **Verriers Rouge**.—This appears to be a compact dwarf-growing form of the Gondouin.

8. **Mallow-leaved** (synonym—New Sweet Red).—This is a strong-growing late variety. Bunches long; berries small, of a pale red colour. Late in ripening and a somewhat poor cropper. The plant is of very distinct appearance, strong, tall-growing, with pale shoots. Leaves large, flat, soft, downy like a Mallow, of a pale green colour, sometimes like the Black Currant.

9. **Laced-leaved** (synonyms—Large Sweet Red, Large Red' d'Hollande à feuille bordée).—A fine, compact-growing; bushy variety. Bunches of a medium size; berries medium, of a pale red colour. A most abundant bearer. Shoots dark, spreading. Leaves dark green with a glaucous hue, and the greater portion, more especially those in the shade, having a narrow silver lacing or border, giving the plants a slight variegated appearance. A very excellent good-habited variety.

10. **Cut-leaved** (synonyms—Feuille laciniée, Eyatt Nova).—Plant of somewhat slender spreading growth. Bunches of medium size; berries small, of a pale red. A very poor cropper. Leaves small, deeply cut, or lacinated and pointed, rendering it very distinct in appearance.

11. **Variegated** (synonym—Feuille panachée).—This is a variegated-leaved form of the common Red. A poor cropper. The leaves are prettily variegated on their appearance in spring, but soon become dull and dingy.

12. **Striped-fruited**.—This, in appearance, resembles the common Red. Berries small, pale in colour, with one or two darker stripes, rather pretty. A very poor cropper. The Gloire des Sablons is stated to be a white variety, prettily striped with red. At Chiswick it proved the same as Gondouin.

13. **Champagne** (synonym—Couleur de Chair).—This is remarkable on account of the pale flesh colour of the berries, and their sweet flavor being exactly similar to the white varieties. Bunches short; berries small. The plant is of dwarf bushy habit and robust. Leaves broad, flat, having the appearance of the Red Dutch. It is an abundant bearer. A desirable variety.

Whites.

14. Common White (synonym—Blanche Commune).—Plant of dwarf bushy habit. Leaves small, deeply cut and crumpled in their appearance. Bunches small; berries small.

15. Wilmot's Large White (synonym—Blanche d'Angleterre).—Plant of free, somewhat erect growth. Leaves large, flat. Bunch of medium size. Berries, large white. A good crop.

16. White Dutch (synonym—Blanche d'Hollande).—Plant, leaves, &c., of exactly the same appearance as the Red Dutch—dwarf, compact, bushy. Bunches, large; berries, large or very large, of a yellowish-white colour, very fine, juicy, and sweet. A great cropper. A. P. BARRON.

A White Black Currant.—I use this name for want of a better. "White Black Currant" is not a more paradoxical expression than "white blackbird," a title I once saw attached to a white stuffed specimen of the *Turdus merula* in a museum. I fancy my Currant must be the same as the one which your correspondent "P." saw in Norway. I have only seen it once, and only one plant of it, and it grew in the flower garden at Drumlanrig Castle, when I was an apprentice there in Mr. McIntosh's time. I have occasion to remember the bush particularly. At the time I was confined to the flower garden department, and having no share in the fruit gathering, the discovery of a bush laden with large green or white fruit in one of the shrubbery clumps while another youth and I were engaged in pulling the seed-pods off the Rhododendrons was to us a notable event. The bush and its fruit were in every way like a Black Currant, except that the fruit was white and transparent. The shoots also were paler in the bark than those of the Black kind. Perhaps the bush is still at Drumlanrig, and Mr. Thomson may be able to give some information about it. It grew on, I think, the topmost clump of shrubs, or thereabouts, in what was called the "Gallow Flat," near the broad walk which runs through the flower-garden from the gate going into the parks on the east.—J. S. W.

A Durable Strawberry.—It is an axiom among many Strawberry-growers that to have an annual crop of fruit a fresh plantation must either be made every year, or every two years at the furthest. To endeavour to make an old bed productive by applying stimulants, and by careful and thorough cultivation of the soil, has heretofore been deemed a waste of time and money; and yet this system is not thrown away in the case of the Triomphe de Gand, when grown on heavy soils. It seems to be an exception to the general rule, for if the plants be kept free from runners, they will bear excellent crops for several successive years; at least, such has been the experience of more growers than one, says the "New York Tribune," who still adhere to this estimable variety.

Pears on Apple Stocks.—M. Carrière, who has made some experiments on this subject in the Jardin des Plantes, finds some Pears to succeed tolerably well when cleft-grafted on Apple stocks, but by no means so well as when worked on the Quince. In looking over the back volumes of THE GARDEN a day or two ago, I found (in Vol. III., p. 289) the following note on this subject:—"Pears grafted or budded on bearing Apple trees is the quickest, surest, and cheapest way in which I ever grew Pears. I never picked better Pears," says the writer (who dates from Kansas), "than I have picked from old Apple trees, topped and budded or grafted with Pears, and they have always borne early and profusely. In large Apple orchards may sometimes be found worthless scraggy trees, and on such I have practised the plan of changing them to Pears, from which I never failed in two years to get a good crop. In some trees the Pear would die out in five or six years, while others were healthy to my knowledge for ten years, and were still doing well when I last saw them in 1865." The effect of Apple stocks is probably restrictive, therefore they would promote fruitfulness at the expense of longevity. It may be as well to direct attention to the fact that it is quite possible for any but the most practised and careful observer to confound the Quince stock with the Apple, inasmuch as the leaves and shoots of the Quince resemble those of some Apples very closely when young; but in the above case, and also in that cited by your correspondent (see p. 351) there does not seem to be much doubt but that true Apple stocks were employed.—B.

Some Varieties of Almonds.—The Royal Almond, or Princess, is also known as the Paper-shell, because of its covering being so thin that it can be easily broken. The kernel is also peculiar for its richness and flavour. It is alleged that this variety can be produced nowhere else than in the south of France, where the warm, dry soil and balmy climate are especially adapted to its cultivation. Next in value and importance comes the Languedoc Almond, which is also a soft-shelled kind, though not nearly so light as the Princess, the shell being thicker but more porous. This Almond is grown

principally in the province from which it takes its name. A large proportion of the Languedoc Almonds are used up in home consumption while still green, and they are said to be delicious when eaten while fresh and milky. The Tarragona Almonds were formerly grown in a small tract of country in Spain in the neighbourhood of the town which gives them their name, but at the present time many Almonds exported from France are classed as and sold under the name of Tarragona. The Provence Almond, which comes next, combines to a degree the qualities of both the Languedoc and Tarragona, but is hardly up to the standard of either. Lastly comes the Ivica Almond, grown on the islands in the Mediterranean Sea, south-east of Spain. There are five islands in the group—Majorca, Minorca, and Ivica being the principal ones—and they all produce Almonds.

Span-roofed Houses v. Garden Walls.—What can be more beautiful than a span-roofed house at this season full of bloom, varying in colour from the white-blossomed Cherry to the lovely tints of our Peaches and Nectarines? What would I not give for a garden enclosed with span-roofed houses instead of brick walls! Under such circumstances Peaches might be had from May to November, and the glorious old Coe's Golden Drop Plums until Christmas. As regards flowers, why, *Marchal Niel* roses would become almost perpetual, and the lovely *Lagergeria*, both red and white, if planted in the borders, would be laden with flowers, which, for bouquets, are quite unmatchable. A skilful cultivator would soon find princely occupants for such structures. Desert dishes would be easily filled with delicious fruit, and dressing the dinner table with choice flowers would be an operation readily performed with houses of this description well-built and properly warmed.—R. GILBERT, *Buryhley*.

Drying Figs.—The process of drying is very simple. The fruit is first dipped in scalding hot lye, made from the ashes of the Fig tree, and then dried in the sun or in ovens made for the purpose. No sugar is used to preserve them, the pulp containing 62 per cent. of sugar. The skin retains so much of the lye that when handled it scours the hands like lixivial salts, and it is in this process which gives them their medicinal value as a gentle and mild laxative, and also as a drawing and healing plaster. They are pressed into drums and boxes for sale, and in many of the islands of the Levant form an important article of food. Great quantities of the brown Turkey Fig are imported into England.

Spur System of Pruning Vines.—A gentleman sought advice from us (J. DOUGLAS, in "Journal of Horticulture") the other day about his Vines. He had a most excellent position in which to grow them, and for several years the Vines have had plenty of leaves but no fruit. The reason of this was not far to seek: the pruning had been done on the short-spur system for years until the spurs were only able to produce weakly growths which never showed fruit, nor would they ever do so. Royal Muscadine is the best out-of-doors Grape, and this was the variety grown; but to grow fruit as well as leaves a certain number of young canes must be trained up from the base of the Vines annually. As the Vines are now starting into growth, they must be disbudded, and a little care be exercised in selecting the most suitable growths. None of the rods ought to be older than three or four years.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Ribston Pippins in Constantinople.—As a proof that it only needs care and proper selection to grow as good fruit in Constantinople as in England or France, I may state that I have eaten delicious Ribston Pippins, grown in the garden belonging to Sergeant Lyne, R.E., the guardian of the British Cemetery at Scutari. One is apt to suppose that a large number of worthless Apples and Pears in Southern Europe and the East generally that the bad fruit is due to the climate, whereas it is really owing to the want of good kinds.—B. B.

Hacon's Incomparable Pear.—This is a large round late Pear of the Easter Beurré type, and one which, on some soils, is said not to bear well or become melting; on the strong soil, however, of the kitchen garden here it is one of our surest-bearing Pears; it has been in use for the last two months, and there are still a quantity of smaller specimens left to become melting. It is richer in flavour and more juicy than the Easter Beurré, and like that kind is a little gritty at the core, especially large specimens of it. It must, I think, be seedling from Easter Beurré, its shape, thick skin, and texture of the flesh indicating that parentage.—WILLIAM TILLEY, *Willeck*.

Paul's Improved Crab.—This was illustrated in the January number of the "Florist and Pomologist." It is highly coloured and a little early, and is therefore regarded as a hybrid between the common Siberian and Red Asturacan, but the fruit-growers of Western America have, according to the editor of the "Gardeners' Monthly," obtained numerous seedling Crabs of this character, as simple seedlings, without any idea of hybridisation.

Hardy Apples.—Mr. Peffer furnished a list, at a late meeting of the Wisconsin Horticultural Society, of those Apples that would pass safely through 39° below zero, namely, *Tetofsky*, *Duchess of Oldenburg*, *Alexander*, *Fall Orange*, *Ben Davis*, *St. Lawrence*, *Red Astrachan*, *Walbridge*, *Haas*, *Plumb's Cider*, *Pewaukee*, *Françoise*, and *Tallman Sweet*.

PLATE XVII.

THE COLUMBINES.

(WITH COLOURED FIGURE OF THE ALPINE COLUMBINE.)

The Columbines rank amongst the next successional flowers to those that belong purely to the spring months—their flowering period extending throughout May and June. Among them may be found great variety in the way of colour—white, rose, buff, blue, and purple, and also stripes and intermediate shades even in the same flower. Then amongst our American introductions we have yellow, orange, and scarlet. Besides colour, too, there is also considerable variation in the shape of the flowers. In some the petals are reduplicated, and in the very double forms of our common garden Columbine, on removing one of the five petals, which are usually distinguished by their brighter colour and almost invariably by the presence of a receding spur-like appendage, it will be found that a series of from six to a dozen, or even more petals, are beautifully arranged one inside the other. Setting aside any economic value the spur-like processes may have, they not only form a pleasing addition to the flower, but they yield well-marked and constant specific distinctions, and in fact have given the origin to the name, both in its botanical and English form—*Aquilegia*, from *aquila*, an eagle, in allusion to the group of spurs incurved and almost hooked at the points, like the talons of the bird in question; and Columbine, from the similarity that the termination of each individual spur has to the short slightly-hooked bill of the dove, *columba*; or as in the case of the Alpine species here figured, where the spurs are short and broad, they collectively remind one of a group of little doves holding a conference. Besides the specific characters just alluded to derivable from these appendages, the whole genus naturally divides itself into two well-marked groups, according as the spurs are incurved at the point or straight. To the former section nearly all our Old World species belong; and to the latter, the more recently discovered denizens of the New World. A glance at our plate will indicate at once that the Alpine Columbine belongs to the former section, although, by the way, Willdenow, in his brief description of *A. alpina*, states that the spurs are straight. It is, however, certain that in none of the plants that I have ever cultivated under the name—and some of them were received direct from their Swiss habitats—was this character observable; in fact, the chief feature by which it may readily be distinguished from *A. vulgaris* consists in the spurs being shorter and thicker than in that species, the petals broader and more expanded, and the whole plant of dwarfer stature, rarely exceeding from 12 in. to 15 in. high. The petals are frequently altogether blue, or merely margined with white; while, as here represented, they are wholly white, with the exception of the spur. The leaves of this, and, indeed, of all the species, are what is called twice or thrice ternate, of a glaucous or greyish-green colour, forming a handsome tuft of foliage, whence arises an irregularly-branching foliaceous cyme, the cauline leaves becoming simpler and less divided as they approach the true bract-like character. The leaflets in our Alpine form are more sharply notched, and the flower-stems are less floriferous than in the common one. That it is a desirable plant for cultivation there can be no doubt; but it is not everywhere that it grows with anything like vigour, and, further, it is rarely met with in our gardens or rockeries. Home-saved seeds are never to be depended upon as they become crossed with our common Columbine, and in a second generation lose almost all their Alpine peculiarities. No doubt seeds of it collected in the Alps would retain more perfectly their special specific characters. The following selection represents such species as I would recommend for general cultivation:—

Common Garden Columbine (*Aquilegia vulgaris*).—This is a familiar occupant of every cottage gardens in which it grows, with a vigour, and increases itself by means of seed with a persistency and a power of variation that is quite surprising. Whether its naturalization in this country was cotermporaneous with that of the ancient Britons is perhaps doubtful, but, be that as it may, it has become thoroughly at home, and no one who has once seen it wild will readily forget the combination of grace and beauty which it presents. In order to stimulate those who possess extensive

wooded estates to its cultivation or establishment along the margins of drives, where shelter is afforded, I would state, that at Broughton Woods, in North Lincolnshire, this Columbine raises its stately erect stems to a height of 3 ft.; and in the month of May, when the Lily of the Valley, which grows naturally by acres and acres, associates with its beauty the further property of delicious perfume, the charm of a drive or walk, especially after a gentle shower of rain, surrounded by such associations, is greater than words can convey. There are thousands of similar situations in domains throughout the country where the seed of the one might be scattered and where the roots of the other might be planted; the rest being left to Nature. Under these conditions the seed-vessels or follicles are not devoid of beauty; their position when in bloom is pendent, but as they reach maturity they become erect, and, when fully ripe and touched by the passer-by, or shaken by the summer's breeze, ring out as a tiny chime of fairy bells. Let me note, *en passant*, that where Columbines are cultivated together in a single bed, as is generally the case in botanical collections, a couple of years will find amongst them a strange specific unity, and the pervading type will be unmistakably our wild Columbine.

Pyrenean Columbine (*A. pyrenaica*) ought correctly to have followed our Alpine Columbine, to which it bears a very close relation. The spurs are longer and more slender, the petals smaller and less expanding, the flower-stem dwarter, less branched, rarely carrying more than three blossoms, the divisional lobes of the leaves are smaller and rounder, the colour more glaucous, and the surface slightly pubescent; it is in cultivation quite as shy as its Alpine brother, and, therefore, will come under my group for future cultural remarks.

Green Columbine (*A. viridiflora*).—This has flowers in which the petals as well as the sepals are of a greenish colour, with here and there blotches of purple—its colour, therefore, can be no recommendation; however, the spurs are reduced to short gibbous processes, and my chief reason for introducing it here is to chronicle the variety of it known sometimes by the specific title of *A. atropurpurea*. In it we have a plant of equal development with our common Columbine—the short spurs of the petals indicate its true specific type. The sepals are green, but the petals a deep rich chocolate. The plant is a vigorous grower, a native of Siberia, and is synonymous with Fischer's *A. dahurica*. It is now many years since I had it in cultivation, and it deserves to take its place amongst the front ranks again.

Meadow-Rue Columbine (*A. thalictriflora*).—This is a dwarf-growing plant, with single-flowered stem, leaves covered with short glandular hairs, and spurs absent altogether; nor are they represented by the gibbous appendages of the last, this fact giving it a botanical character which I think will render a record of its existence a matter of interest to some of your readers.

Siberian Columbine (*A. glandulosa*, synonyms *jauncida* and *concolor*) is by a long way the most charming of all the species hitherto noticed, and may be said to occupy an intermediate position between the two sections. The spurs are of moderate length, slightly incurved, but not hooked, the sepals large and wide-spreading, of a deep purplish-blue, the petals are large, wide, expanded, and margined, with a broad band of white; when growing well, which it rarely does in the south of England, or indeed south of the Tweed, it produces a number of these large blossoms, raised well above a mass of light grey finely cut foliage, and, under those circumstances, it is a plant that has few equals; it is a native of Siberia, where it appears to be very widely distributed, chiefly occurring along the margins of the mountain streams. It has one singular peculiarity, that whereas the seeds of all the other Columbines have a bright perisperm, those of this species are unburnished, arising from little corrugated markings with which the microscope shows them to be covered.

Slender-spurred Columbine (*A. leptoceras*).—This according to priority, should yield to the name given to it by its discoverer, Mr. James, viz., *A. cornuta*; but seeing how characteristic is Nuttall's name of the special peculiarity of the plant, and as the original seeds sent by Burke from the Rocky Mountains did not yield a single blue form, I think we shall not be far wrong in recognising Thompson's plant as a blue variety of *A. leptoceras*. When I say that the mouth of the wide-expanded corolla is nearly 3 in. in diameter, and the graceful outward-curving slender spurs are above 2 in. long, some idea may be formed of the beauty of this plant; the sepals, petals, and spurs are of an ochroleucous colour—that is, a mixture of yellow and white, with a decided predominance of the white. Burke described it in a letter as the plant which excited his admiration, most of all those that he obtained in his excursion on the Rocky Mountains, which, by the way, yielded many gems; and truly, were its size of bloom and elegance supplemented by a little more vigour of constitution, it would have few rivals in either the herbaceous border or the rockery; *A. macrantha*, of Hooker and Arnott, is a synonym.

COLUBINA (C. ALPINA)

Blue Rocky Mountain Columbine (*A. leptoceras corulea*).—This has flowers suffused with a delicate blue tint. My own experience is that they are also smaller in size than the type; but, like several we have already alluded to, it is rarely met with in vigorous growth, under which conditions it might possibly require some modification in this respect.

Canadian Columbine (*A. canadensis*).—This was once the only New World Columbine, having been introduced from Virginia by the younger Tradescant. It may be taken as the type of the scarlet-orange and yellow group. The flowers are of much smaller size than any of those just described; this, however, is amply compensated for by the brilliancy of the scarlet colour of the sepals and the erect somewhat capitate spurs, and the bright yellow of the petals. The true *A. canadensis* is a slender grower, scarcely exceeding 1 ft. in height, with sharply-notched irregularly-ternate leaves. As seen in cultivation it often presents a decided hybridity, under the influence of which an increased vigour of growth and a decreased brilliancy of colour are manifest.

Skinner's Columbine (*A. Skinneri*).—This, though evidently allied to the previous species, is abundantly distinct. The flowers are supported on long slender pedicels, the sepals being greenish-coloured and lanceolate; the petals are small and yellow; the spurs are nearly 2 in. long, of a bright orange-red, and attenuated into a slightly incurved club-shaped extremity; the leaves are very glaucous, their divisions being sharply and irregularly incised; the flower stems acquire a height of 18 in. to 2 ft. Though coming from so far south as Guatemala, owing to the fact that it is met with in the higher mountain districts, it is nearly, if not altogether, hardy, and should be more frequently cultivated than it is. Here, again, hybridity steps in and too frequently mars its beauty.

Californian Columbine (*A. californica* or *A. truncata*).—This is the strongest grower of all the American species. Its radical leaves are somewhat scanty and supported on long petioles; the divisional lobes are well separated. The tendency of the plant is to produce one bold woody stem, which, under favourable conditions, will rise to the height of 3 ft.; the sepals are orange-coloured and blunt-pointed, being closely adpressed to the petals, which are also blunt; they give one the idea that they had been trimmed round with a pair of scissors; hence the appropriateness of the specific term *truncata*. The spurs are long, bright orange, more attenuated than in Skinner's Columbine, but to appreciate the full beauty of the flower it must be turned up from its naturally pendent position; then the beautiful shell-like arrangement of the petals becomes at once visible, the bright yellow marginal line gradually shading off into deep orange. The seeds of this species should be carefully looked after, as having once blossomed the old plant is liable to perish; and, further, I have never been disappointed when the seedlings diverging from their parent type in character.

Golden Columbine (*A. chrysantha*).—This is a very fine strong-growing plant, sending up from amidst a mass of delicate glaucous leaves a number of stems to a height of from 2 ft. to 3 ft. As the specific name indicates, the flowers are of a golden or rather bright canary yellow, which remarks as regards colour equally apply to sepals, petals, and spurs alike. It is, I believe, a native of the Rocky Mountains and California, and has but one fault, that it develops its tender leaves very early in the season, and is liable to have much of its beauty damaged by our April frosts and snows.

Himalayan Columbine (*A. kanariensis*).—This is one of the best; it was discovered by Thompson at Kanora, in the Western Himalayas, and more recently at Tibet, where it grows at an altitude of from 12,000 ft. to 15,000 ft. It is a slender plant about 15 in. high; leaves few in number, beautifully glaucous, and covered with short glandular hairs; the flowers are small, the sepals white, expanding horizontally; the petals also white at the margin beautifully reflexed, the blue colour becoming more pronounced in the spurs, which are perfectly erect and rigid, and culminating in an azure club-shaped process at each terminal point. This, for delicacy and beauty, takes the same position amongst Columbines that *P. capitata* does amongst Primulas.

Our figure of *A. alpina* is from "Alpine Plants," published by Messrs. Bell & Daldy.

Cultural Remarks.

To those who are familiar with the vigour of our common garden Columbine it must appear strange that there should be any difficulty in the cultivation of the various species that I have enumerated in the above descriptive article, and yet I know of no plants that are so capricious; take, for instance, the charming *A. glandulosa*, grown like a weed, at Mr. Grigor's nursery, from whom years ago I had a hamper of plants in full

blossom—a sight worth going miles to see. This was succeeded by a hamper in the early autumn, and by an abundance of seed, but, beyond an odd half-starved blossom, the spring result was most unsatisfactory; the plants raised from seed being no better. This, however, was on the hot gravelly sub-soil at Kew. Nevertheless, I am compelled to say the result here, on our cold clay sub-soil, proved no more satisfactory even when artificially made beds of peat and leaf-soil were prepared for them. Nor is this species an exception; it is, as I trace it, characteristic of all the mountain species. Let us for a moment examine the conditions under which they naturally grow, and possibly we may get some clue to those conditions essential to success. In almost every case their natural habitat is on the banks of mountain streams, where, on the ledges formed by a deposit of gradually accumulated rich alluvial soil, their roots find the special nourishment they require with perfect drainage; and no doubt the shelter of their position, supplemented by the overhanging branches and adjacent vegetation, helps to protect their young spring growth, which I take to be a matter of the utmost importance, as on its protection hinges the vigour of the summer bloom. Mr. Whittaker, of Morley, near Derby, has been very successful with both *A. glandulosa* and the blue variety of *A. leptoceras*, and he tells me that he grows them in a thoroughly drained, deep, rich, alluvial loam-soil; the same were the conditions of Mr. Grigor's success, and, in adapting those conditions to the various localities where their successful culture is aimed at, cultivators must use their own judgment, always remembering that shelter from direct morning sunshine should be secured for the spring foliage.

Grafting on Roots.—Good grafting is the readiest way by which

a great many tuberous, herbaceous, and shrubby plants may be propagated; and among those multiplied in this manner in most good nurseries, we may instance Peonies, Roses, Clematis, and Aralias. This plan of propagation has many advantages, and may be resorted to with success in the case of such plants as do not strike readily from cuttings; of these *Bignonia*s, *Wistaria*s, and many other shrubs are familiar examples, and of late years American fruit-growers have propagated Vines, Apples, Pears, and Plums on an extensive scale in this manner; they dig up the roots of the wild species and varieties of these fruits from the woods, and graft them during the winter months, after which they are buried in a cool but frost-proof cellar, so as to be ready for being planted in spring. In the case of choice decorative shrubs and other plants, root-grafting is most successful when it is done in a heated propagating-case, and it is advisable that the roots be started in a warm atmosphere, so as to have them a little in advance of the scions. It is a matter of but little moment what kind of grafting is adopted, provided it be neatly and quickly done with a clean, sharp knife. Whip, cleft, splice, or side-grafting or inlaying are alike successful, and that method may be used which is most convenient. Our illustration shows how root-grafting is effected in the case of the Clematis, *Wistaria*, and *Dahlia*; but the intelligent operator may adopt any plan which convenience or ingenuity may suggest.—H. B.

The Produce of French Gardens.—According to some figures cited by M. Joly before the Central Horticultural Society of France, and taken from the records of the Custom House, the total quantity of fruits exported to England, Belgium, and Germany amounted in 1874 to nearly 80,000 tons. In 1874 the quantity exported was more than double that in 1873. Of dried vegetables over 23,000 tons were exported in 1874, Chestnuts 6000 tons, and of Potatoes the enormous quantity of nearly 175,000 tons. The amount of money we now pay to the French for garden produce is enormous. Those weights are surprising enough in themselves, but when it is considered that a great deal of the produce is of the very choicest description, and worth a good deal per pound (as in cases of early Asparagus, choice fruit, winter Lettuce, &c.), then the meaning of those figures may be fully understood. Our growers, and, perhaps, our politicians, too, would do well to bear those facts in mind, for there must be something instructive in the conditions which give rise to such a state of things.

Root Graft of
Wistaria.

THE LIBRARY.

REMINISCENCES OF FEN AND MERE*.

In this pleasantly-written book, we have details of the fens of Norfolk, Cambridge, and Lincoln, and especial reference to the enormous drainage works by which hundreds of acres of these submerged lands have been reclaimed and made amenable to cultivation. The work also contains much pleasant information regarding the sports, amusements, and occupations of the fen people, together with notes on the various distinguished artists who have at one time or other visited the district, and painted its Dutch-like scenery. The work is profusely illustrated with tinted plates, which vary much in quality, and some few of which had better have been omitted; the best of them is a "Deserted Mill in Winter," by Mr. E. W. Cooke, R.A. The wild plants of the district are sparingly alluded to; and Ophrys Lœselii, Typha minor, Parnassia palustris, Pilularia globulifera, and two or three forms of Drosera, are cited as not uncommon. The extremely rare Swallow-tail and Large Copper Butterflies were also formerly found here, but of late years they have disappeared. We are told that the American Water-weed (*Anacharis alinastrum*) was first found in a small pond in Sir George Staunton's park, whence it was sent to the Cambridge Botanic Gardens as a curiosity, and from there it somehow escaped into the Cam, which soon became choked by it, and thence it spread rapidly all over the fens. One of the characteristics of this plant is, that pieces cut or broken from the parent plant sink to the bottom of the pond or stream, where every particle rots and grows. The author furnishes some interesting information respecting deposits of Hazel Nuts, which are found nearly all over the Fen district; the origin of such deposits is doubtless owing to the sudden submersion of woods by inroad made by the sea. *A propos* of the supposed subsequent germination of some of these ancient nuts, the author quotes a letter from Dr. Hooker, from which it appears that the late Dr. Lindley's oft-quoted report of the germination of Raspberry seeds taken from a Roman tomb at Dorchester, where they had been buried from 1600 to 1700 years requires to be received with some degree of caution. It appears that the late Prof. Henslow took some of the seeds home and found that in all of them the germ was destroyed, and that they could not possibly have germinated. It appears that the ancient seeds were handed round a crowded meeting on an open flat tray, and that on a similar tray fresh seeds were exposed for comparison. It is therefore supposed that some of the fresh seeds became accidentally mixed with the old ones, and that it was in reality these which grew into plants as related in the "Theory of Horticulture," and not those taken from the tomb in question. The book will be welcome to many, especially to those who reside in the districts to which it more particularly refers.

JUMPING SEEDS AND GALLS.

At a late meeting of the Academy of Sciences of St. Louis, Mr. C. V. Riley exhibited certain seeds which possessed a hidden power of jumping and moving about on the table. He stated that he had recently received them from Mr. G. W. Barnes, of San Diego, California, and that they were generally known by the name of Mexican jumping seeds. They are probably derived from a tricoocous Euphorbiaceæ plant. Each of the seeds measures about one third of an inch in length, and has two flat sides, meeting at an obtuse angle, and a third broader, convex side, with a medial carina. If cut open, each is found to contain a single fat, whitish worm, which has eaten all the contents of the seed and lined the shell with a delicate carpet of silk. The worm very closely resembles the common Apple worm (*Carpocapsa pomonella*), and indeed is very closely related, the insect being known to science as *Carpocapsa saltitans*. It was first recorded by Westwood in the proceedings of the Ashmolean Society of Oxford, in 1857 (iii. 137, 138), and repeatedly referred to under the name of *Carpocapsa Dehaisiana* in the "Annales" of the French Entomological Society for 1859.

The egg of the moth is doubtless laid on the young pod, which contains the three angular seeds, and the worm gnaws into the succulent seed, which, in after growth, closes up the minute hole of

entrance, just as in the case of the common Pea weevil (*Bruchus pisii*). Toward the month of February the larva eats a circular hole through the hard shell of its habitation, and then closes it again with a little plug of silk so admirably adjusted that the future moth, which will have no jaws to cut with, may escape from its prison. A slight cocoon is then spun within the seed, with a passage-way leading to the circular door; and the hitherto restless larva assumes the quiescent pupa state. Shortly afterwards the pupa works to the door, pushes it open, and the little moth escapes. When ripe, the shell is very light, and, as the worm occupies but about one-sixth the inclosed space, the slightest motion will cause the seed to rock from one of the flat sides to the other. But the seed is often made to jerk and jump, and, though this has been denied by many authors, Mr. Riley has had abundant proof of the fact, and has seen the seed jerked several lines forward at a bound, and raised a line or more from the surface on which it rested. If the seed be cut, the worm will soon cover up the hole with a transparent membrane of silk; and if two of the opposite angles be cut, the movements of the worm can then be seen if the jerk be held against the light. It thus becomes evident that the jerking motion is conveyed by the worm holding fast to the silken lining by its anal and four hind abdominal prolegs, which have very strong hooks, and then drawing back the head and fore-body, and tapping the wall of its cell with the head, sometimes thrown from side to side, but more often brought directly down, as in the motion of a woodpecker's head when tapping for insects. In drawing back the fore-body the thoracic part swells, and the horny thoracic legs are withdrawn, so as to assist the jaws in receiving the shock of the tap, which is very vigorous, and often given at the rate of two a second and for twenty or more times without interruption. It is remarkable that this, of all the numerous seed-inhabiting Lepidopterous larvæ, should possess so curious a habit. The seed will move for several months, because, as with most Tortricoidous larvæ, this one remains a long time in the larva state after coming to its growth and before pupating.

The following account of the plant, received through Captain Polhamus, of Yuma, is given by Mr. Barnes. It seems to be called both *Yerba de flecha* and *Colliguaja* by the Mexicans:—"Arrow-weed (*Yerba de flecha*) is the name which the shrub bears that produces the triangular seeds that during six or eight months have a continual jumping movement. The shrub is small, from 4 to 6 ft. in height, branched, and in the months of June and July yields the seeds, a pod containing from three to five seeds. These seeds have each a little worm inside. The leaf of the plant is very similar to that of the 'garambullo,' the only difference being in the size, this being a little larger. It is half an inch in length and a quarter of an inch in width, a little more or less. The bark of the shrub is ash-coloured, and the leaf is perfectly green during all the seasons."

Mr. Riley stated that the seed of *Tamariscus* was known to be moved by a Coleopterous larva (*Nanodes tamarisci*) that fed within it; and he concluded by describing and exhibiting a still more wonderful jumping property in a seed-like body which may be observed in some American woods. It is a little spherical, seed-like gall produced in large numbers on the under side of the Post and other Oaks of the white Oak group. This gall drops in large quantities to the ground, and the insect within can make it bound twenty times its own length, the ground under an infested tree being sometimes fairly alive with these mysterious moving bodies. The noise made often resembles the pattering of rain. The motion is imparted by the insect in the pupa and not in the larva state. Mr. Riley presented a description of the gall, which may be known by the name of *Quercus saltatorius*, the black fly which issues from it having been described as *Cynips saltatorius* by Mr. H. Edwards, of San Francisco.

The Root-Cap.—The idea held by the earlier botanists, that the tips of all roots consisted of spongy masses of tissue, by means of which plants were enabled to soak up their food from the soil, has, with the aid of the microscope, been entirely discarded. The term spongiole, which was given to these theoretical bodies, is a landmark of departed ignorance, and furnishes a striking contrast with the known structure (*viz.*, the root-cap), with which the tip of every growing root is covered. With the leading botanists of to-day a root is considered to be an outgrowth protected by a cap. This definition seems very short, but if anything further is added, there comes with it a number of exceptions. The name which this covering to the root-tip has received is in itself very descriptive, as it is truly a cap, consisting of a number of layers of quite dense cells surrounding the extremity. These root-caps vary in size in different species of plants; sometimes they are so small that only with the high powers of the microscope can they be seen, while on the other hand they may be readily observed with the naked eye.—B. D. HALSTEAD, in the "Gardeners' Monthly."

* "Reminiscences of Fen and Mere," By J. M. Heathcote. London: Longmans, Green & Co. 1876.

THE INDOOR GARDEN.

SLENDER-LEAVED BOWSTRING HEMP.

(*SANSEVIERA CYLINDRICA*).

THE *Sansevieras*, which are nearly related to the *Dracenas* or Dragon-trees, are natives of the warmer parts of Africa and India, several species being grown in our hot-houses mainly for the beauty and singularity of their leaves, which are all radical, and either strap-shaped as in the well-known *S. variegata*, or thong-like, as in the subject of our illustration. The tough fibres of the long narrow leaves have been utilised for cordage, and especially for bow-strings by the African aborigines; hence the popular name. The species which we now figure is well worthy of cultivation, its leaves being of a dark green colour, covered with zebra-like markings of a lighter tint. All the species grow well in a warm greenhouse or plant stove, as they form singular and attractive objects planted out in the deep moist border of a warm conservatory, a position in which they make vigorous growth. *S. guineensis* is the African species, and *S. Roxburghiana* is the Moorva of the Indian peninsula, its fibre being very tough and durable, and especially suitable for the manufacture of fine string or cordage. *S. zeylanica* and *S. cylindrica* are not uncommon in gardens where they are grown as fine-foliaged plants, the flowers of all the kinds being small and unattractive. B.

SOLOMON'S SEAL AS A POT PLANT.

THIS is one of those old-fashioned plants that have of late years had a new career opened up to them. From time immemorial this hardy British plant has found a place in herbaceous beds and borders, but very often in a poor and exhausted state. To grow it in perfection it requires to be frequently divided, and to be planted in light rich soil. Left to itself, it becomes overcrowded, and soon exhausts the soil in which it grows by its vigorous habit and rapid increase of stems. Under good cultivation the latter rise from an average height of 18 in. or 2 ft. to 3 ft. or more; and to see plants so high, clothed with fine foliage from base to summit, and furnished with silver bells—well-nigh innumerable—is one of the most unique and pleasing sights which we have among flowers. This distinctive beauty, too, is far more apparent in pots than in the open ground; for the Solomon's Seal is one of those plants that improve upon a nearer or closer acquaintanceship. Few plants, indeed, have a more striking effect on a stage or shelf. Plants of it with single or three or more stems are admirable for window furnishing. The form and

style of growth are also well adapted for the furnishing of vases or baskets, and the plant is as accommodating as it is beautiful. It may be potted up any time after October and forced into flower with a moderate heat. Small pieces with single stems may be potted in light soil and flowered in 4-in. pots. These small plants are useful

for small stages or for cutting for vase furnishing as soon as they are in flower. Pieces with from three to four shoots in 6-in or 8-in. pots are the most useful and effective; though large masses are also sometimes potted up for centres of groups, for which the peculiar arched style of growth of the Solomon's Seal renders it especially well fitted. Plunge the plants in a bottom-heat of 55° or 60°, and subject them to a surface temperature of 55°. With such moderate forcing they will soon advance into full leaf and flower. As soon as this stage is reached, they may be removed to a cooler temperature of the sitting-room or window-garden, in either of which places they will continue long in bloom, and cannot fail to give satisfaction. The foliage is almost as beautiful and useful as the flowers. There is a peculiar freshness and beauty as well as originality of style about the Solomon's Seal, which gives it a special distinctness and value among Ferns and similar plants. We have found the weaker shoots that have not flowered particularly useful for mixing among flowering masses of forced Lilacs, Rhododendrons, and Azaleas, and the branches with their accompanying wealth of pendent bells are perfect in their blending of white and green. These same flowers, mounted either singly or in threes, also form unique and valuable material for bouquet makers. They work in well with other flowers, and form dividing lines or margins of great distinctness. But it is as a pot plant that we would especially recommend the Solomon's Seal. By dividing a stool or two of it every year and planting at 18 in. or 2 ft. apart in fairly good soil, a sufficient stock would always be kept up for potting, for forcing, or for potting up merely for flowering in the window or conservatory. For the latter purpose the plants need not be potted up till the middle of March. They might then be set in a cold pit or any out-of-the-way place till they have made some progress, or be placed in the window at once, where the whole of their growth could be noted and seen. After flowering, they could be returned to the ground, to be kept clear of weed during the summer, and potted up again the next or following season. There are several varieties, such as *Polygonatum angustifolium*, or narrow-leaved; *P. latifolium*, or broad-leaved; *P. multiflorum*, many-flowered; *P. vulgare flore-pleno*, double-flowered; and a small variety, *P. vulgare minor*. But the latter is really the most useful for the purpose of potting up as above described, and most of the other varieties are comparatively rare. As to the double variety, the doubleness may be said to spoil its beauty, as it does also that of the Lily of the Valley, to which, notwithstanding its stature and character, the Solomon's Seal is nearly allied.—"Villa Gardener."

Slender-leaved Bowstring Hemp.

other varieties are comparatively rare. As to the double variety, the doubleness may be said to spoil its beauty, as it does also that of the Lily of the Valley, to which, notwithstanding its stature and character, the Solomon's Seal is nearly allied.—"Villa Gardener."

FREESIA LEICHTLINIANA.

This charming and delicately-perfumed little plant has now been in bloom in my conservatory for over a month, having commenced to open its pretty flowers (which are of a delicate primrose yellow, with a deep and clearly marked golden blotch on the front of the lower petals) about the end of February, and continuing in beauty throughout the whole of March. The perfume exhaled from its blossoms is of an exquisite and peculiar character, not exactly resembling that of any other plant with which I am acquainted, but reminding one of what the concentrated essence of the common Primrose of the woods might be. This pretty plant was first introduced into this country by the New Plant and Bulb Company, at Colchester, who exhibited a well-bloomed potful of it at the spring show of the Royal Botanic Society, Regent's Park, last April, when it received a botanical certificate. A woodcut of it was given in a contemporary on the 8th of May last, but it greatly exaggerates the size of the flowers and the stature generally of the flower-stem and foliage. My tallest flower-stem was but 8 in. in height, and most of the others not more than 7 in., whereas the woodcut gives the idea of an altogether stronger, thicker-stemmed, and taller-growing plant than this little gem really is. It is a native of the Cape of Good Hope, and is exceedingly quick of increase, the two bulbs sent me last season from Colchester having divided into half-a-dozen bulbs, nearly as large as I received, all of which have bloomed well this spring, and no fewer than twenty off-sets, varying from the size of a Sweet Pea to a full-sized Marrowfat edible Pea, and even two of these bulblets are now showing heads of bloom. It is, therefore, evident that it is an extremely free and early bloomer when properly managed, as though at Colchester the blooms did not begin to expand till the middle of April, with me without any kind of forcing they began to open on February 27. It is now also seeding freely, and is said to be in all probability perfectly hardy.

W. E. GUMBLETON.

Boiler Water for Plants.—There is a pit here some 40 ft. long used during the winter for bedding stock. It is heated by pipes connected with the boiler, which warms the greenhouse, &c.; the feed-tank is supplied from the Water Company's constant service. Until lately all water used had to be carried into the pit, with the further disadvantage that, being drawn direct from the main, it had to be used in a cold state. The various paragraphs that appeared in THE GARDEN some time since had much to do with the carrying out of the following arrangement:—The hot-water pipe in the pit was tapped in the under side, and a short length of iron pipe was screwed in, connected with a 3-in. ball-cock enclosed in a small cistern, the same as those used for boilers of kitchen ranges; this communicates with a 30-gallon galvanised iron tank standing under the stage, the water in which constantly always stands at the level of that in the small cistern, thus affording a convenient supply of water with the chill off at all times. It was fixed on the 29th of February last, and has given every satisfaction, not the slightest prejudicial effect on the plants having been noticed. Of course, with the above plan it is essential to have an ample supply with which to feed the tank of the boiler.—H. A. W., Surrey.

White-flowered Indian Jessamine (*Jasminum Sambac*).—This is a free-growing stove climber, producing abundance of somewhat primrose-shaped white flowers, quite as strongly scented as those of a *Gardenia*; the small flower-sprays of it are, therefore, useful for bouquets. An old plant of it here, which flowered more or less all last summer and autumn, and which was potted and cut back about a month ago, is now producing quite a multitude of flowers from the old wood, and will no doubt go on flowering for a long time. It does best in a 14-in. pot, I think, and a larger size if the plant be some years old. It delights in loam and peat in equal parts, with a little sand and rotten cow manure, and the shoots should be trained near the light. An ordinary stove temperature suits it, but it must not be subjected to a too close atmosphere. Pinching the summer growths sometimes increases the number of flowers; but it blooms most freely in early spring, and it is the better for being pruned in pretty closely before potting, which causes it to break back, and keeps such a straggling subject within bounds, and all the young shoots produce flowers. *Jasminum Sambac* should be grown extensively wherever sweet-scented flowers are appreciated, and it makes an excellent companion to the Neapolitan Violet.—J. S.

Best Winter-flowering Gesnera (*G. cinnabarina*).—Of the several popular varieties of this Christmas-blooming species, the above is generally reckoned the best, being a very free flowerer, and of robust habit, with very ornamental foliage. One plant in a 6-in. pot makes a specimen of itself, very suitable for a table or vase. *Gesneras* may be propagated by means of leaves, buds, or cuttings;

but as bulbs are about as easily procured as these, they are in every way better. A succession of flowers may be had by starting the bulbs in succession; but now is the time to put in those intended for winter decoration. The most expeditious way is to place the bulbs about 1 in. asunder in a shallow pan, using a compost of equal parts of sifted loam, peat, or leaf-mould, and sand. Cover them over $\frac{1}{2}$ in. deep, and plunge them in a bottom-heat of 60° or 85°. When fit to handle well, pot them off into 6-in. pots, using the same light compost, with a little rotted manure added, and after potting, place them in stove-heat, and keep them there till they flower. In fact, to get them to throw their flower-spikes well up above the foliage, and to expand freely, they should not be subjected to a lower temperature than from 65° to 75° in winter, and should have as much sun and light at that season as possible. The plants may be freely watered when growing, but good draining must be first insured. When done flowering, let them go gradually to rest, withholding water altogether in the end, when they may be stored till starting time on a dry warm shelf. A low damp temperature is fatal to the roots.—CHEFF.

The Calla at Home and in Cultivation.—Many years ago, at the junction of the Black and Yellow Rivers, at the Cape of Good Hope, I saw untold millions of *Callas* growing in the swamps, lakes, and lagoons. I believe they never dry up in that region during the hot and droughty seasons peculiar to Africa, but are at all times submerged. There are but few plants capable of existing under such dissimilar conditions in cultivation as the *Calla*. Treated as an aquatic, a terrestrial, or a sub-aquatic, it readily adapts itself to the situation, and flourishes. Notwithstanding that they succumb to zero's icy touch, they will endure considerable cold, and live, if preserved from frost.—W. T. HARDING.

Evils Arising to Plants from Painting with Coal Tar.—A few years ago, says a correspondent of the "Gardeners' Monthly," I had some experience with coal tar in two forcing pits, an account of which may be interesting. The wooden frame-work of the beds having become decayed, it was necessary to renew them. In order to make the new frames last as long as possible, the insides of the planks were given a coating of coal tar. The work was done in summer, so that it had time to dry and harden before the soil was put in. I had recommended to my employer pitch tar in preference to the cheaper article, fearing that bad effects might result if the high temperature in the pits should melt the coal tar; but in the autumn, when the soil was placed in the beds, so hard and dry had it become that I thought the work could not be done better, or more cheaply, and my earlier apprehensions were removed. Winter-flowering plants and early vegetables occupied the beds, and all did well for about three months after being planted. The weather having become intensely cold, the heating apparatus had to be kept at work night and day. Just at this time the plants seemed to lose their healthy look; *Roses* and *Bouvardias* began to sicken, and their leaves to turn yellow and fall off. I at once suspected the coal tar, and in order to remedy the evil as far as possible, I removed these plants out of the beds and potted them. I found that their young roots were black and lifeless from being poisoned by the tar. The continual heat from the pipes immediately under the beds had melted it, and the gases being absorbed by the soil poisoned it. In other parts of the pits, *Carnations*, *Heliotropes*, and *Stocks* were planted; but they did not appear to suffer in the least. Lettuces, however, didn't seem to like their quarters any better than the *Roses* and *Bouvardias*. Parsley grew quite as well as if nothing unfavourable had touched its roots. I had no satisfaction from these pits that season, and when summer came round again, I took the first opportunity to remove all traces of what had given me so much trouble, and refitted the frames with hard Pine planks, after which all went well.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Madame Vaucher Pelargonium for Cutting.—This well-known variety is still the most useful kind for affording white flowers in a cut state, or for their effect on the plants at this season. Although one of the oldest kinds it is not grown in great abundance about London.

Croton trilobus Alberti.—This is one of the hastiferous forms of *Croton* which has been recently introduced from the Islands of the South Sea. In the present form the leaves are wedge-shaped at the base, with a pair of lateral lobes, produced at different points in different leaves, but within the lower half of the leaf, the middle lobe being oblong-spatulate, bulged near the end, and terminating in a short acute point. The middle and lateral veins are yellow, while a few yellow dots are scattered aberrantly here and there over the surface—this yellow colouring passing to red as it acquires age and exposure.—W. BELZ.

Double Yellow Auricula.—I am pleased to find that this old but resuscitated plant has flowers not only double, but deliciously sweet-scented, a property which renders them doubly attractive in the greenhouse.—A. D.

TREES AND SHRUBS.

GIGANTIC ELM AT SCHIMSHEIM, HESSE.

ALTHOUGH not the largest Elm tree in Germany, the Schimsheim Elm, of which we give a woodcut from a drawing from nature, by Herr C. F. Seidel, is worthy of notice on account of the beauty of its form. The tree in question stands in the market place of Schimsheim, a small village some four or five miles from the town of Worstadt, in the Grand Duchy of Hesse, and is described by Herr Seidel as being nearly 100 feet in height. The bole is hollow, but the remaining wood is sound and healthy. The circumference of the stem, close

NEW LIGHT ON TRANSPLANTING TREES.

PERMIT me to ask Mr. Michie if he has well weighed all the circumstances of the case which he records at page 364, and if his long experience in transplanting trees generally confirms the newly-proposed view, that trees transplant more successfully without previous preparation in the shape of root-pruning than with it? Cultivators will have a difficulty in accepting this new doctrine, for the simple reason that it is opposed both to theory and practice. There is an accumulation of evidence to the contrary. It is not generally necessary to prepare trees a year or two previous to planting in the way Mr. Michie describes, but that a previous check greatly insures a successful removal, I have no doubt whatever. I never knew an

Elm at Schimsheim, Hesse.

to the ground, is 50 ft., at 1 in. above the surface (3.28 ft.) 44 ft., and at 2 in. (6.56 ft.) 34 ft. There are, unfortunately, no historical particulars extant about this tree, the date of its plantation cannot, therefore, be ascertained with accuracy. Herr Seidel estimates its age at a little over 600 years. It must be remarked that the Elm is not indigenous to that part of Germany, but is an introduction from Southern Europe. In France the Elm was not regularly introduced until the middle of the sixteenth century, about the time of Francis I. Although not the tallest Elm in the Fatherland, the Schimsheim giant ranks amongst the four great trees of Germany. The Luther Elm at Pöfflingheim exceeds it in height by nearly 50 ft., while its circumference is only 25 ft. at 1 ft. above the surface of the ground—the Schimsheim giant exceeding it at that height by nearly 10 feet.

instance in which its advantages were not apparent. Is not the whole practice of transplanting nursery stock periodically based upon the fact that it multiplies the roots, keeps them "at home," and thereby insures a safe transfer when the plants leave the nursery; and in this respect what difference is there between a young and an old tree? Is it not a well-known fact, also, that the first root-pruning or lifting of a fruit tree which has not been operated upon before completely stunts it for the first year or two, while you may move it every two years afterwards without preventing growth or losing a crop of fruit? What is it which makes an old tree more difficult to move than a young one, though both may be equally vigorous? Is it not because the check is greater owing to the difficulty in getting a proportionate quantity of roots away with it? Cut round it, however, pretty close to the stem; sever all the rambling

tap and other roots, and in one or two years you can move the tree without much trouble, and with a tolerable certainty of success. Failure in mostly all cases is the result of a severe check to the roots, a too sudden stoppage of the supplies; but withdraw the supply by degrees, and there is little danger.

J. S. W.

Brilliant Tree Foliage.—In the village of Union Springs, near Cayuga Lake, a tree-planting society was formed many years ago, and several hundred trees of the Sugar and Red Maples were planted along the different streets. Nearly every autumn these make a gorgeous display of crimson, scarlet, pink, and orange, in an almost endless number of shades and different modes of blending. The absence of frost till late in autumn, owing to the proximity of Cayuga Lake, increases the effect. There are two or three trees of surpassing splendour, which maintain this distinction every year. Why would it not be as desirable to give a brilliant termination to the foliage of the season, as to plant for the two or three days of the blooming season in spring?—"Albany Cultivator."

The Value of Timber in the Highlands.—An illustration of the value of timber on waste lands in the Highlands is afforded by a sale of wood which took place on the estate of the Earl of Cawdor, in Nairnshire, the other day. In 1820, two hills on the Cawdor property of about 800 acres in extent, and of almost no agricultural value, were planted with Fir and other trees, and after successive thinnings, the sale of which realised large sums, the remainder of the wood has just been sold off for the sum of £16,000. The sums realised for the wood on this waste land during the fifty years is stated to be equal per acre to the return for the best arable land in the country.

Conservation of Forests.—This is unquestionably a subject of great importance. It is now occupying, says Dr. Balfour in an address to the "Scottish Arboricultural Society," the attention of the Government of India, and of many other Governments, and it will sooner or later engage that of all our colonies. The physical history of every country proves incontrovertibly that a moderate extent of forests, especially on mountain slopes and elevated rocky ground, where tillage is impracticable, promotes in a high degree both the agricultural and manufacturing interests of individuals, as well as the physical soundness and productive resources of extensive countries. It appears that the influence of forests in a physical, economical, and hygienic point of view, is deserving of a more complete investigation than it has yet received. By felling trees which cover the tops and sides of mountains, men in every climate prepare, at once, two calamities for future generations—the want of fuel and scarcity of water.

Colossal Redwood Trees (Sequoia sempervivens).—At a recent meeting of the California Academy of Sciences, Dr. A. Saxe made a preliminary report on a grove of colossal Redwood trees that have been discovered on the San Lorenzo. The trees are in a forest around the head waters of that stream. One of them eclipses all that have been discovered on the Pacific Coast. Its circumference as high as a man can reach, standing and passing a tape line around, is a few inches less than 150 ft. This is beyond the measurement of any of the Sequoias in the Calaveras Grove. The height now is estimated at 160 ft., and a part of the top lying on the ground river off by lightning or a tornado, is over 100 ft. in length. The other trees in the vicinity are not so large, but all are of immense girth. This region has but recently been explored, and what other marvels of vegetation it contains remains to be seen. The stumps of Redwood trees of immense proportions have been reported from time to time to the Academy by explorers in the Mt. Diablo range along the hills back of Oaklands; but now we are likely to have further discoveries of these majestic conifers in their glory, height, diameter, and foliage.

The Hardest Gum Trees.—Young plants of the Tasmanian *Encalyptus coccifera* are reported to have borne 17° of frost in France this season without receiving any injury. This species is doubtless one of the hardest of the genus, as it inhabits the summits of mountains 3000 ft. to 4000 ft. high in Tasmania. It has long been cultivated in England, and it was figured in the "Botanical Magazine," plate 4637, in 1852; Sir William Hooker there says, "It forms a most graceful tree, 20 ft. or more high, in the gardens of Mr. Veitch [presumably of Exeter] and about London, braving our severe winters when trained to a wall." From the latitude and altitude of the home of this species, one would expect it to be much harder than *E. polyanthemus*, which is rarely injured in the open ground at Kew. We may here mention a few other Tasmanian species likely to prove hardy in the south-west of England and Ireland.—*E. Risdonii*, the Drooping Gum of the colonists, described as a handsome tree; *E. unigera*, a tree with spreading branches,

sometimes attaining 50 ft., not uncommon in Alpine districts; *E. vernicosa*, a dwarf bushy shrub with very small leaves, found at the summits of Mount Patigue and Mount Lapeyrouse; and *E. Gunni*, a small tree, abundant in Alpine districts at an elevation of 3000 ft. to 4000 ft., often forming small forests; it is the "Cider Tree" of the colonists. Seeds of other species, also found on the mainland of Australia, should be procured if possible from Tasmania, because they are likelier to prove hardier from thence. Such are *E. coriacea*, *E. amygdalina*, *E. globulus*, and *E. viminalis*.—"Gardeners' Chronicle." [When in California, we were told by an extensive planter of *Encalyptus* that *E. Gunni* proved to be a very hardy species there.]

Scotch Fossil Trees.—We learn that six trunks of large trees have been obtained at Craigleith Quarry since 1826. The largest, 36 ft. long and from 12 ft. to 14 ft. in girth, has been taken to the British Museum, and is to be set up erect. Another is nearly 30 ft. long, and has been removed to the Botanic Gardens. The trees were Conifers. The surface of each is bituminous coal, varying from one-twentieth of an inch in thickness to 2 in. The trunks inside of this coaly exterior consist of carbonate of lime, carbonate of magnesia, carbonate of iron, and free carbon in varying proportions.

Viburnum dilatatum.—The "Botanical Magazine" describes this as a hardy white-flowered Japanese shrub, with large leaves somewhat like those of the Hazel Nut. There are ten or twelve Japanese species of *Viburnum*, including the present plant, which promises to be a welcome addition to our gardens. Some of the *Viburnums* owe much of their beauty to the fact that they bear enlarged but abortive flowers in a way analogous to those of the *Hydrangea*. In the present species, however, the flowers are all normal, forming dense rounded clusters at the apex of the downy stem.

Tropical Trees During the Dry Season.—Professor Ernst, of Caracas, states that many woody plants of the Venezuela flora lose all their leaves during the dry season, even when the ground is copiously watered for the purpose of preventing their fall. Several large-leaved plants, such as *Cassia*, *Mahogany*, and many others, exhibit this phenomenon. The new foliage starts usually when the rainy season sets in, but if the rains come very late, as they did in 1875, many of these trees unfold their buds and develop their leaves at a period when the ground is dry and hard, the tropical heat very intense, and the air extraordinarily dry. This curious periodicity has been casually noticed by several writers, but no explanation has been hitherto offered. Professor Ernst has given this subject careful study, and now states that in general those trees which cast their foliage in the dry season have compound leaves of rather delicate texture. From such leaves transpiration is exceedingly rapid, and early carries away all the available water. When there is no more moisture within reach of the plant, the leaves separate from the stem. In this wholly or partially leafless condition the trees remain until the end of April or the beginning of May, when the moist winds from the north-west, as precursors of the tropical rains, awake the slumbering vegetation. Of course the trees cannot absorb by their parts above ground any great amount of moisture, if they do any at all, but the slight transpiration which had been going on from stems and young shoots is now checked. The small amount of moisture which the roots can take from the parched soil is not without speedy effect upon the branches and buds to which it is carried. The buds soon open. But in the spring of 1875, when there was not a cloud to be seen in May, and the west wind at evening brought little relief from the scorching drought of the day, and the baked crust of the soil everywhere showed no trace of moisture, the trees put forth their leaves as usual!

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Acuba Pollen.—How long will this keep good? I have some which I bottled in the spring of last year, and it looks, through a pocket-lens, as fresh as some which I have just taken off the same plant.—W. T. T.

Flowers of the Judas Tree in Salads.—In Constantinople I much enjoyed the flowers of the Judas when used in salads. They are gathered fresh from the tree which blooms gloriously in these regions, and are mixed with good *Cos* Lettuce. The flavour is pleasantly acidulous, and the effect in the dish rather pretty.—C. W. QUIN.

The Flowers of the Chinese Quince.—The flowers of *Cydonia sinensis* are, though not so far as I have seen them, conspicuous away from the tree like those of the Japan *Pyrus*, yet they are so very beautiful that I am surprised the plant is not more grown for their sake. The flower-buds, when exposed to the sun, are a deep rich crimson; when the flowers open and the buds unfold into shell-like petals, the old highly coloured portions of the outside of the bud remain just as they were in colour, the inside of the petals and the parts of the outside not exposed to the light in the bud stage being white. The result is a variegation of a most pleasing kind. I speak of the tree as grown on walls in the south of England.—V.

A HANDY GARDEN MARKER.

MARKERS, for use in the garden, are among the implements that are home-made; in a rough way, pins are set in a piece of joist, and this, when furnished with a handle, answers a good purpose. Those who like to have their garden implements neatly made will be glad of the following description, sent us ("American Agriculturist") by Mr. D. S. Hibbard, of Carroll County, of a marker which is unlike any we have before figured, and which has the advantage of being readily adjustable to make drills at any required distance apart. He says:—"Plane a piece of inch-board 4 in. wide, and from 4 ft. to 6 ft. long (mine is 6 ft.), and fasten a handle 6 ft. long to its middle, at right angles. The handle should be beveled, so that when in use the board may be in a level position, as in figure 1, and should be firmly screwed on, as it can not be braced. Upon the upper side make scratches square across the board, at every inch of length, and mark the foot and halves and quarters of feet. Then make several pieces of board (fig. 2), each 1 ft. long on top, about 3 in. wide, with each end shaped like a sled-runner, and sharpen the bottom edge suitably for marking drills in the soil. In the middle of each piece, near the top,

Garden Marker.

make a mortice 1 in. by $\frac{1}{2}$ in. Fit them so that they can be easily slipped on to the long board, or head of the marker, and fastened in any place by wedges. These bits of board can be fastened across the long one at any desired intervals, and the scratches for feet and inches will help to set them square, and to regulate the distances. Such a tool, with good usage, will last a lifetime, and will, I think, mark drills more smoothly and regularly than any arrangement I have seen described."

BOTANICAL TOUR IN THE TYROL.

EARLY in August I started by train between five and six A.M., for Atzwang station, about fifteen miles north of Botzen, that being the nearest point from which to commence the ascent of the Schlern. From Atzwang to Ratze's Baths is a zigzag path up the mountain-side, a sort of rough, narrow horse road by which passengers and provisions are conveyed to the baths, about nine miles distant. Directly on leaving the station the river Eisack is crossed by a rudely but firmly constructed wooden bridge, made of Pine boards. As soon as I had crossed the bridge, and begun the ascent, I met with some well-known Alpines, such as *Dianthus superbus*, *Campanula rapunculoides*, *Saponaria ocyroides*, *Polygala Chamæbuxus*, *Anemone pulsatilla*, *Selaginella helvetica* (this is very abundant where shaded by shrubs and trees), *Digitalis ochroleuca*, and *Orobanchus vernus*. In some places in the wood, where there were few trees, the ground was green with *Vaccinium Vitis-Idæa*. Higher up, on emerging from the wood, I found walls everywhere charmingly clothed with *Asplenium Trichomanes*, *A. viride*, *A. septentrionale*, and *Cystopteris*. The fields and hedge banks were gay with *Salvia pratensis* and *Prunella pyrenaica* or *P. grandiflora* (?). After walking some little distance I came upon a few scattered houses, which constitute the small village of Völs. Beyond this the ascent is not so steep for a mile or more as hitherto. In several places the path winds round, or has been cut through hillocks of stones and earth. On these I saw *Sempervivum arachnoideum* (the Cob-webbed Houseleek), *S. montanum* (?), *Saponaria ocyroides*, *Helianthemum vulgare*, *H. Fumana*, *Dianthus sylvestris*, *Nothochlæna Marantæ* (a solitary specimen), *Saxifraga notata* (?), and *Globularia cordifolia*. The last-named is a pretty dwarf evergreen Alpine of trailing habit, with small, roundish, leathery leaves, and pale bluish flowers. For stony ground it forms quite a dense covering. The next few miles, through Alpine meadows, were not particularly interesting until the Pine woods were reached, immediately beneath the enormous perpendicular cliffs of the Schlern. Here I met with *Pyrola secunda* in great profusion, also *Campanula cæspitosa*, a species resembling *C. pusilla*, but with flowers, intermediate between those of the last-named species and

C. Zoyssii, the mouth of the corolla being contracted like that of the latter species. It was growing in great profusion amongst the washed down *Wabris* of Dolomite limestone, the fragments being of the size of *Alnus*, or even less, and intermixed with very small quantities of soil. Onwards I went through woods composed of Spruce, Silver Fir, and Pine, a somewhat dreary walk, with only the huge summit of the Schlern to be seen, and, as you proceed, a running stream, which when crossed the white-washed buildings of Ratze's Baths become discernible. A more out-of-the-way place it would have been difficult to find in which to build, for the buildings are erected on the highest available situation in the narrow gorge between the Seisser Alp and the Schlern. The waters, which contain sulphur and iron, are conveyed, for the benefit of invalids, considerable distances down from their respective springs to the bath-house by means of hollow tree pipes, the thin end of one being let into the thick end of the other, so as to form a line of continuous piping, sometimes above, at other times under ground.

After arranging to stay at Ratze for a short time, I retraced my steps towards the little wooden bridge, and then to the left, intending to visit the perpendicular cliffs which overlook the bath-house and the Pine forests. Here *Pyrola secunda* was especially plentiful; I also saw on a shelving bank an *Epipactis*, but not in flower. After climbing and scrambling for about a mile, I remarked the charming little *Pyrola uniflora* beneath a huge Silver Fir. It was growing among the decayed leaves on the shady side of the tree. A large blue Monkshood, measuring from $1\frac{1}{2}$ ft. to 2 ft. high, was growing in the more open places, while higher up I came upon acres of the Alpine Rose (*Rhododendron intermedium*), and still higher occurred the dwarf *Rhododendron hirsutum*. Immediately beneath the cliffs, the first plant which attracted my attention was an annual bearing scarlet fruit in whorls up the stem which was much branched and about 12 in. high; it was growing in limestone sand or dust, beneath an overhanging cliff, where it would seldom if ever be subjected to rainfall; I have not yet been able to ascertain its name. All along the ledges and face of the cliff, as high as the eye could scan, *Aquilegia Bertoloni* was displaying its charming blue flowers and yellow anthers. Next occurred that most singular of all Alpines, *Phyteuma comosum*, a plant with stiff, leathery, glaucous, jagged leaves, and enormous flower-heads nestling close to the face of the rock, and resembling small purple horns. Its flowers vary in colour, some being much darker than others, but their prevailing colour is light blue tipped with brownish purple. To all appearance it was growing out of the solid limestone rock, the roots penetrating far back into extremely narrow cracks. It is a most difficult plant to extricate. A little further on I found another *Phyteuma* new to me, *P. Sieberi*, a kind having flower-heads about the size of those of our native *P. orbiculare*, with very pubescent leaves, and blue flowers from 2 in. to 6 in. high. Still higher up plants known to me as rarities became abundant, such, for example, as *Saxifraga Burseriana*, *S. Valdensis*, *Soldanella minima*, *S. alpina*, *Cystopteris alpina* (?), *Pinguicula alpina*, and *Asplenium Sselosii*, the last a very small and singular little Fern, with fronds about 1 in. high, cleft into three small divisions at the apex; it was growing sparingly on a north exposure on detached masses of rock. Of *Pedicularis* I observed various species; also *Pædota Bonarota*, *Ranunculus montanus*, *R. alpestris*, *R. Thora*, *R. rutifolius*, *Silene acaulis*, and *Viola biflora*; but what pleased me most was a beautiful little *Campanula*, of very dwarf and tufted habit, with minute roundish-toothed leaves covered with hairs. Its flowers were large, of a bright yet dark purple colour, and extremely handsome; it was growing like its neighbour the *Phyteuma*, on the face of the solid cliff in the smallest cracks imaginable. Its flowers were so conspicuous that I could see them on the face of the cliff more than 1000 ft. above me. When I got back to Botzen I ascertained from a small illustrated work on Alpines that it was *C. Morettiana*.

My next excursion was to the summit of the Schlern, which is 9000 ft. above the level of the sea. From the baths it is reached by a narrow and steep winding-path up the Seisser Alps; after the first 2000 ft. have been surmounted the table-land of this great Alps is reached. Here many châteaux are scattered about where thirsty travellers can generally obtain milk; then, by turning south-west and crossing the stream on large stones one gains the flank of the Schlern, whence, to the summit, is a very steep grassy slope varied with hillocks, rocks, and stones. Among the Grass, not far from the water, were growing fine specimens of *Allium Victoriæ*. From about 1000 ft. above this to the summit the pasturage was enriched with Alpines, amongst which I remarked a pure white flower about the size of a shilling, which I took, looking at it from a distance, to be *Dryas octopetala*, but which I found to be *Anemone baldensis*, a showy plant, which grows from 1 in. to 9 in. in height. Then came *Potentilla nitida*, with large and showy pinkish flowers, and also a solitary specimen of it with blossoms of a bright rose colour,

reminding one of those of *Rosa pyrenaica*. Sparingly scattered over the turf was *Campanula pulla*, bearing large dark blue solitary flowers; it was not in tufts, as it grows in gardens, but always solitary, and furnished with flowers larger and finer than those produced under culture here. I also noticed more *Phyteuma Sieberi* in the fissures; likewise *Saxifraga cœsia*, *Oxytropis cyanea*, *Aronicum glaciale*? *Anemone vernalis*, *Arbutus alpina*, *Primula longiflora*, and *Achillea Clavenna*. *Gentiana verna*, *G. nivalis*, and *G. brachyphylla* were sparingly scattered about, but not to be seen without looking for them very closely among the herbage, as with the exception of a few plants of *G. nivalis*, they were not in flower. On a shelving slope of *débris*, a little below the summit on the east side of the mountain, I saw *Papaver pyrenaicum*, which in such a situation was very conspicuous. The little white-flowered *Androsace obtusifolia* was also to be found here, as was likewise that Alpine gem *Myosotis alpestris*, in tufts about 3 in. in diameter, and from 2 to 4 in. in height, literally covered with bright blue flowers with pink centres. On my descent I noticed on the flank of the mountain acres of the dwarf *Pinus montana*, with stems about the thickness of one's thigh, the first foot or so of which was erect, while the upper portion was sub-prostrate, sparingly clothed with foliage, the whole being not more than from 4 to 6 ft. in height; beneath this the ground was carpeted with *Rhododendron intermedium*. WANDERER.

The Pecan Tree.—I satisfied myself, by experiment and investigation, of the value of this as a timber tree, wagon and carriage makers, wherever they have used it, testifying of its value as being equal to the best of White Ash for all purposes of carriage manufacture, possessing equal durability and greater strength and elasticity. At various points on the Mississippi River steamboat carpenters who have used it found it a valuable timber in boat building. As a fuel it has no superior. I find it as easily transplanted as any tree I ever handled, having never lost a tree. It is of vigorous growth, clean, and healthy. The Pecan tree ordinarily commences bearing at about eight years of age. It bears one of our finest Nuts, which sold for the past six years at an average price of £1 per bushel. The Pecan tree is grown readily from the Nut, if it be not allowed to become dry before planting.—L. HARRISON, in "Prairie Farmer." [The fragile and well-flavoured Nut of this tree is now on sale in some London shops. Is the tree planted in England, and how does it get on with us? I do not remember seeing it, but fancy it would thrive well on the chalk in the south of England.—V.]

THE PEAR-SHAPED WALNUT.

(*JUGLANS INTERMEDIA PYRIFORMIS*.)

As a supplement to our article on the "Walnut and its Varieties," given in last week's GARDEN, we furnish a few more wood engravings illustrating the peculiarities of the curious variety *Juglans intermedia pyriformis*, a kind which well deserves more than a mere casual mention. The tree which bears this Walnut is of vigorous habit, with stout branches covered with a smooth dark brown bark speckled with grey. The fruit is Pear-shaped or, perhaps to be more correct, Fig-shaped, as will be seen from fig. 1. The sarcocarp is of a bright green covered over with grey points, which are closely similar to those which are formed on the husk of the *Juglans nigra*. The shells are woody or rather bony, very hard, with the two halves so closely united that they cannot be separated even at maturity. The kernel is small, and is strongly enclosed by the folds of the inside of the shell, and is almost separated in the middle by a thick, hard, and ligneous division. What little there is of the kernel is of an excellent flavour. This plant is said to be a true hybrid between *Juglans regia* and *Juglans nigra*, and holds a place exactly intermediate between the two. The general appearance of the full-grown tree recalls that of *Juglans regia*, which it also closely resembles in its foliage. But it is quite otherwise with the fruit, which much more closely resembles that of *Juglans nigra*, as will be seen from the sections as shown in figs. 2, 3, 4, and 5. Fig. 2 gives a transverse section of the fruit of the common Walnut. In this section it will be noticed that the shell is thin and fragile, yellow and smooth, or, at any rate, but slightly fissured on the outside. The inside shows a membranous division which is frequently wanting altogether at some points of the circumference. The kernel, which is comparatively large, is nowhere

attached to the shell, so that it separates from it with the greatest facility. The two halves of the shell, too, divide with perfect ease, simply lying together without any permanent connection. Fig. 3 gives a transverse section of the fruit of *Juglans intermedia pyriformis*, with the kernel, and fig. 4 gives a transverse section of an empty shell. Fig. 5 gives a transverse

Fig. 1.—Fruit of *Juglans intermedia pyriformis*.

section of the fruit of *Juglans nigra*, and a mere glance at the three sections will show how closely they resemble each other. The shell of *Juglans intermedia pyriformis* is very hard, and being of a greyish brown colour, with the surface finely fissured, with pointed asperities rising up here and there. The interior divisions are as hard as the shell itself, limiting the

Fig. 2.—Transverse section of Common Walnut.

Fig. 3.—Transverse section of fruit of *Juglans intermedia pyriformis*, with kernel in situ.

Fig. 4.—Transverse section of Fruit of *Juglans intermedia pyriformis*, without the kernel.

Fig. 5.—Transverse section of fruit of *Juglans nigra*.

size of the kernel by their thickness, already reduced by that of the shell. The two lateral divisions are thinner, but, as shown in fig. 4, form the cavities next the walls of the shell. These divisions so thoroughly enclose the kernel that it can only be extracted in broken pieces. In the Black Walnut (*Juglans*

nigra), of which a transverse section is given in fig. 5, the shell is extremely hard and bony, of a greyish brown, the surface being finely fissured. The interior divisions, too, are ligneous and greatly diminish the size of the kernel, which, like that of the *Juglans intermedia pyriformis*, is so closely enveloped by the internal divisions that it can only be extracted in fragments.

In our last article we described several Walnuts occupying an intermediate position between *Juglans regia* and *Juglans nigra*, but in none are the peculiarities of their ancestors so evenly divided as in the interesting variety under consideration.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Winter-flowering Stove Plants.—One of the best decorative autumn and winter flowering plants that amateurs who have the convenience of a stove can grow is the *Poinsettia*. It is possible that the new double variety may ultimately supersede the old form, but until it becomes more plentiful, and its superiority in every way to the old one has been proved, it will be well to continue the cultivation of the latter. There are several ways of growing the plant, which is easily managed provided a few essentials to its well-being are kept in view, but through a mistaken idea that all plants grown in pots must be made to assume one uniform shape, the *Poinsettia* is often subjected to an unnatural torturing process that goes far to destroy its true character, and to prevent its gorgeous head of inflorescence attaining the effective size which it would acquire if treated more in accordance with its natural habit of growth. It grows best from cuttings struck in spring and confined to moderate-sized (say at most 8 or 9 in.) pots; and no attempt should be made to induce it to produce more than a single stem, which, if really well managed, will attain a height of 3 or 4 ft., and bear a head 18 in. in diameter. Thus grown *Poinsettias* are much more effective when intermixed with other plants in the stove than in any other way by which they can be produced, but such plants can only be had by starting the old stools into growth sufficiently early to get cuttings struck in time to admit of their attaining strength enough to bear such heads. Through a disposition to flower *Poinsettias* in a dwarf state, the old plants are often kept from starting into growth too long, thus producing cuttings much later than they should be, which is simply a mistake, as the dwarfing process, when required, can be much better attained by other means. Plants that flowered through the winter, and which have since been kept dry at the roots, should immediately be cut back to within 8 in. or 9 in. of the pot, watered, and replaced in heat. The cuttings, from their soft nature, do not strike well if allowed to get so long as to necessitate their being taken off in the way usual in the case of most plants; they should not be allowed to get more than 6 in. or 7 in. in length, and ought to be then taken off with a heel consisting of old wood, and placed singly in small pots covered with a bell-glass, in a heat of 70°, shaded and kept moist. Thus treated, not one in a score will fail to root; after this they should be potted on in good loam, well enriched with decomposed manure, kept through the summer with their heads close to the glass, in a light house or pit, encouraging them to grow as strongly as possible without an attempt at stopping. If a portion be wanted dwarf, they may be had in flower 8 in. or 10 in. in height by the autumn; when the growth is nearly complete, half-sever the tops 6 in. below the points, and leave them in that condition for a week, until the base of what is to be the future plant has become collused; then cut through the remaining portion, and put the tops singly in 3-in. pots, drained and nearly filled with good rich sandy soil, and a little sand on the surface; place them in a brisk heat under bell-glasses, shading them and treating them generally, as is done in the case of ordinary cuttings. They will root in a couple of weeks, when they should be gradually exposed to the air of the house; after which they should be moved into 5-in. or 6-in. pots. This process, if they are wanted very dwarf, may even be repeated a second time, but in neither case will the head of inflorescence be so large as when the plants are allowed to flower without the heads being subjected to this manipulation. After the first lot of cuttings have been removed, the old stools will break afresh, when they should be shaken out, placed in pots a couple of inches larger, and grown on. These are the plants to make into bushy specimens, as the shoots can be trained down in autumn close to the pots, if such a form be required. In the warmest parts of England, these stools may be planted out-of-doors in June in a sheltered border in loose open soil, from which they can be lifted in September, and potted without injuring their roots, so as to cause leaf-shedding

In this way *Poinsettias* will flower in a dwarf state. Another nearly allied plant, *Euphorbia jacquiniiflora*, should now be propagated for winter-flowering. To all who have a stove this is more indispensable as regards flowers in a cut state than the *Poinsettia*; in propagating this *Euphorbia*, it is of even greater importance than in the case of the *Poinsettia*, that the cuttings should be taken off with a heel, for if they are made from the points of the shoots, as is usual in the case of most plants, few will strike root; put the cuttings singly in small pots; they will root in a short time under a bell-glass, if placed in a temperature of 70°; after they are struck, move them into 4-in. pots in good sandy loam, to which add one-sixth of rotten manure, keeping them close to the roof-lights, so as to induce a short bushy habit. Later in the season, when they require it, move them into 7-in. pots. *Plumbago rosea*, *Sericographis Ghiesbreghtii*, *Eranthemum pulchellum*, *Justicia carnea*, and *Thyrsacanthus rutilans* should now be propagated without delay, as upon the young plants getting early established in their pots, so as to be strong before autumn, depends the way in which they may be expected to flower during the autumn and winter; for it is not wholly upon their size that their ability to produce abundance of bloom rests, but also upon the growth having time to get matured sufficiently before the flowering season arrives. Out of the immense number of different species of plants that have been introduced to this country, many of which will flower at some time during the winter, amateurs are sorely puzzled what to select and what to reject; but the above may all be relied upon as the best that can be used, possessing the advantage that they will grow in small pots, and are equally adapted for cultivation by those who have a small heated house as by those with unlimited stove room. To the above may be added the exquisitely-scented *Jasminum Duchesne d'Orleans*; this is a beautiful creamy white double flower, individually as large as an ordinary double Daisy, quite as fragrant and much superior to the old double *J. Sambac*. Cuttings should now be put in made from the freest young shoots that can be got that have no disposition to flower, as these latter will not root so well; it is a sparsely-rooted subject that does not require very much pot room, and it is better to have a number of moderate-sized plants than to attempt to grow large specimens. It will be found to succeed well in good fibrous peat, to which sufficient sand to keep it porous should be added; the plant is somewhat subject to the attacks of red spider, and needs the constant use of the syringe to keep it under. This *Jasminum* is rather inclined to a thin straggling habit, to correct which the shoots should be stopped occasionally through the summer. For the summer decoration of amateurs' greenhouses, there are few plants more suitable than the tuberous-rooted *Begonias*. Their brilliant colours and habit of flowering without intermission for several months render them most desirable either for ordinary decorative purposes or for the production of cut flowers, their elegant drooping form particularly befitting them for associating in vases with flowers of more erect growth. If bulbs be now placed in pots filled with ordinary sandy soil mixed with one-sixth of leaf-mould and a little rotten manure from an old hot-bed, they will grow well. Do not put them at first in pots of too large a size, and shift them into others as soon as the first are filled with roots. They do not require strong heat to start them, an intermediate temperature answering better; or they will succeed in a greenhouse altogether, but will not flower so early, and consequently to so long, as when first placed in heat, and afterwards transferred to a cool house or pit. In sheltered warm localities they will thrive well out-of-doors in the summer, being all but hardy, provided their roots are mulched in winter, and planted in a dry situation.

Greenhouse.—The plants here will now require additional water. Azaleas, that have pushed a considerable amount of young shoots (which they will do before the flower-buds begin to swell, if the plants be in good health and strong), will, consequent upon the quantity of young leaves they thus make, need more water. Those who have not had much experience with these plants frequently suppose when growth is made to a considerable extent before flowering, that it will interfere with their blooming; but such is by no means the case, although when the plants in this condition have been allowed to flag from want of water, I have known the undeveloped flowers to be killed in the buds, and the cause attributed to the existence of the young shoots, which in subsequent years were removed as they made their appearance before flowering, to the certain weakening and serious injury of the plants.

Bedding Plants.—Whatever propagation of the more tender subjects that are not generally planted out before June has yet to be done, should be completed as soon as possible, or the season will be too far advanced for the plants to attain their natural size. Attend to the hardening off of all the plants that are to be put out first; but it is not advisable to plant too soon, however fine the weather may be, as the changes are so rapid and often unexpected, that a single night's return of low tem-

perature, even if it does not kill the plants, frequently induces such a stunted condition that weeks elapse before they begin to again grow.

Flower Borders.—Now is a good time to plant the principal collection of Gladioli; if desired, a few may be reserved for planting in later that will bloom after the others. The soil for Gladioli should be of a strong loamy nature, well dug and made moderately rich. I have found a dressing of soil benefit them materially. Do not plant where the ground is full of the roots of shrubs, or still worse, of deciduous trees, for where these exist, it is impossible for the Gladioli to succeed, as they are robbed in two ways—viz., by the soil being impoverished, and the moisture from it being absorbed by the roots of the trees.

Kitchen Garden.—Early crops of Cabbages and Cauliflowers that have been recently planted out have this spring been more than usually knocked about by the late strong winds. When these crops are in this way worked loose at the collar they should at once have the soil drawn up to them, for, if allowed to remain to be rocked about by the wind in all directions, they will not thrive. Where Globe Artichokes are required later in the season than the established beds will continue to bear, suckers should now be taken off from the stools of existing beds. A planting trowel is the best implement for such a purpose. Each sucker should have a few roots attached, and should be planted before it is allowed to flag in a piece of deeply-dug, well-manured ground. Plant them three or four together in clumps, 3 or 4 in. apart, the clumps 3 ft. asunder in the rows, with 4 ft. between the rows; water them well, and place 10 in. or 12 in. flower pots over each lot of suckers for a week or two until they have begun to grow, tilting the pots so as to give light, shading the plants from the sun. Planted now when the suckers have got considerable strength, they will produce a good crop, much superior to that borne by suckers taken off earlier plants, which latter are a long time in acquiring strength, but they must be shaded as above recommended until they have got a firm hold, or they will not succeed nearly so well.

Conservatory.

Creepers, such as Passifloras, Tacsonias, and others of that class that flower on the current year's wood, should now receive their final pruning by cutting the whole of the old shoots completely out, leaving only the main stems and branches. Any young growth that may have started on the old spurs from which the branches were cut away some time back will require thinning and regulating, so as to leave only just sufficient to depend in a loose natural manner. Creepers are often made to assume a stiff formal appearance by too much tying and training; this should be avoided as much as possible, as they never look so well in any way as when drooping gracefully down from the roof without any restraint. Where there is sufficient height in the house to allow creepers to depend from the girders, nothing can equal the beauty of the different varieties of Passifloras, Tacsonias, and Bignonias as decorative plants for furnishing the roof. In such positions, with their main stems tied firmly to the proper supports, the young branches can be allowed to hang down and festoon overhead in the most natural manner, thus clothing that portion of the house with the richest drapery of foliage imaginable. Where roofs of conservatories are furnished with quick-growing plants of that class it is necessary to look them over frequently that they may be kept properly thinned and regulated, or they soon become a tangled mass, and lose much of their natural beauty. With the rapid growth such roof-climbers are now commencing to make, abundant supplies of water at the roots will be necessary, especially where the roots are at all confined and the borders are of limited extent. See that what is given is in sufficient quantity to soak thoroughly the whole of the soil, as the principal roots of established plants like these are sure to be deeply down in the earth, and, therefore, out of reach of moisture unless water be given them in large quantities.

Pillar Plants.—Among these the deliciously fragrant *Jasminum gracile* should always have a place, as it is so powerfully scented as to fill a whole house with its perfume. It is equally adapted for clothing a wall, or for growing as a roof-climber, except in houses that are high and lofty, in which case it would hardly be strong enough. The leaves are of a most pleasing pale green colour, beautifully glossy and fresh looking, and as it is not at all subject to insects it is admirably adapted for growing in houses attached to mansions or dwellings. *Rhynchospermum jasminoides* is sure to commend itself for like positions, and is a good companion to the above, to which its blooms have a striking resemblance. *Cantua dependens* should have plenty of sun and light to ripen its growth. It is one of the grandest of all plants that can be had for a pillar, as there its delicate long pink trumpet-shaped flowers depending so gracefully from the ends of the shoots can be seen to the greatest perfection. This is a plant

that is now unfortunately but seldom met with, and yet there are few more beautiful or deserving of cultivation. If planted out in light, dry, sunny positions, it grows and flowers in the freest manner possible, and when laden with bloom is an object of great attraction. Unfortunately, it is rather subject to red spider, but this can be kept down by a free use of the syringe and plenty of cold water.

Baskets well filled are a great ornament to conservatories where the roof is sufficiently light, lofty, and not overcrowded with creepers. There are few better plants for filling these than that fine old *Pelargonium*, *Rolission's Unique*. This displays its beauties to better advantage when suspended in this way than it is capable of doing when grown as a pot-plant, as in the former position it rambles over the sides of the basket, and droops with its load of flowers in a natural manner. A few plants of the common Ivy-leaf worked in with it greatly heighten the effect by the contrast. *Achimenes* are likewise very suitable for this kind of work; but, to have them in perfection, baskets should be at once filled with some that are started, and then placed in the stove or some other light warm house. Rough peat and old partly-decayed Moss answer admirably for growing them in, and are more retentive of moisture than most other mixtures—a point of some consideration where the air has full play on all sides of the soil. Ferns, too, are very graceful ornaments when placed in well-filled globular baskets; choice should be made of such as are of drooping pendulous habit, such as *Asplenium flaccidum*, *Woodwardia radicans*, and others of that class. Plants of *Nephrolepis* are likewise graceful adjuncts to basket work, as they soon send their creeping roots over the entire surface, and clothe the whole of the basket with their elegant-looking fronds. *N. tuberosa* and *N. exaltata* being greenhouse kinds, and very strong growers, make noble masses that are in good condition all the year round, and are possessed of a permanent character. For smaller sizes, *N. pectinata* is a perfect gem, having fronds from 12 in. to 18 in. long, that are very useful for cutting. During the summer months such grand sorts as *N. davallioides* may be trusted for a time, the gracefully-arching fronds of which, when suspended, have a most striking effect. Many others, such as *Acrophorus immersus*, *Adiantum setulosum*, and others of that class that travel beneath the soil and send out their fronds in various directions, are all suitable for baskets for suspending in sheltered shady positions, where they are sure to be a source of interest and exceedingly ornamental. Fern baskets come in as valuable decorations for winter, when flowers are scarce and the principal beauty of roof-climbers is over. Now is a good time to fill and prepare some by giving them a summer's growth in moist shady houses to get them well established. The baskets should be well lined round with a good thick layer of long Moss, and be then filled with rough lumps of peat and loam. These should be distributed around the sides at equal distances apart, and then have a copious watering to settle the soil amongst them. Fires in the above structures may now be entirely dispensed with for the season, except it may be requisite to dispel the damp should a continuance of wet weather prevail. In cases where *Camellias*, &c., are planted out so as not to be separately treated from others in bloom, the latter should, as far as possible, be grouped together that the plants may be syringed, to encourage a free growth and prevent insect-pests from establishing themselves on them, which they assuredly will if the atmosphere be at all dry. A moderate degree of shade will now be requisite to plants in bloom, in addition to that afforded them by the creepers, which at no time should be allowed to become sufficiently thick and thus obstruct the light in a way to interfere with the requirements of the flowering plants beneath them. If shade be applied for a few hours during the hottest part of the day it is all that is requisite at this early season, as when it is allowed to remain on long it has an injurious effect on the lasting properties of the flowers, which under such conditions do not assume their natural colours. A very dry state of the atmosphere is alike fatal to a continuance of bloom, as the tax on the plant through the rapid evaporation from its leaves and flowers is greater than the roots can support, and they therefore quickly relieve themselves of the load by shedding their bloom. Syringing among the pots early in the morning and again in the afternoon when the days are bright and sunny will counteract any such tendency, and will likewise assist in maintaining the plants in a healthy vigorous state. Such free-growing subjects as *Cytisus*, *Azaleas*, and similar plants now carrying a quantity of bloom, must be liberally supplied with water at the roots, of which they can scarcely have too much if in good health and confined to moderate-sized pots.

Hyacinths.—As these go out of bloom they should be planted out at once in the open borders, unless wanted for spring gardening to form beds, in which case, place some thoroughly decomposed manure, in well-prepared ground, under the roots of each, to assist them in completing their growth, and forming fresh spikes of bloom

for next season's display. Solomon's Seal, Dielytra, Lily of the Valley, Spiraea, and similar hardy plants, when turned out of the conservatory should either have the protection of glass for a time, or be placed in some warm, sheltered position where they can be well attended to with water till they ripen off naturally and die down. Plants that have once been forced, if well cared for and grown on afterwards are in a far better position for flowering early again than those that have not been so treated; even the hardy Lilac, that is supposed to stand almost any rough treatment, well repays looking after and growing on when it has served its purpose in the conservatory, or supplied the flower vase with bloom. There are few places, however, where such things can be accommodated with glass room, or have time devoted to them in watering to forward them for future use.—J. SHEPPARD; Woolverstone Park.

Orchids.

If not already done, it is now a good time to go through all Orchids, potting such as may require it, and cleaning and re-arranging others. Many of the *Odontoglossums*, particularly of the *O. crispum* class, will be starting into growth, and will be benefited by being placed in fresh material, but do not disturb well-rooted plants which are doing well merely for the sake of potting them; be careful to crock the pots nearly two-thirds of the way up, and place a layer of fresh Sphagnum over the crocks to preserve the drainage in good order. I find that the cool-house *Odontoglossums* like good fibry peat broken to about the size of hen's eggs (or smaller for small pots), and fresh living Sphagnum Moss; the latter is a matter of importance, for when the Moss does not grow the plant invariably suffers. In other houses plants, the roots of which are in bad condition, should be potted at once. *Pot Aerides*, *Vandas*, &c., in Sphagnum; *Leelias*, *Cattleyas*, &c., in good fibry peat with a little Sphagnum, and keep them moderately dry for a time after potting. See that shading for all the houses is in proper working order. Look after thrips, scale, &c., as much as possible, for if not kept down now they will be more troublesome by-and-by. I find it best to wash the plants with weak tobacco-water, which, if made with pure tobacco, does not injure them in the least. The temperature for the week should be—warm house, from 65° to 70° by day, and 60° at night; intermediat or Cattleya house, from 60° to 65° by day, and 55° at night; *Odontoglossum* or cool house, from 55° to 60° by day, and 50° at night. The higher day temperatures are for sunny days. Those who have all their Orchids in one house must treat it as an intermediat house, so disposing of the plants that the cool house varieties are in the coolest places and the warm house ones in the warmest places.—JAMES O'BRIEN.

Indoor Fruit Department.

Vines.—Grapes produced by Vines in pots will in many instances be fit to cut this month. Where such is the case maintain a drier atmosphere and a freer circulation of air than has hitherto been thought necessary. Suspend by degrees a free use of the watering pot. The increased amount of air will tend to check red spider, but where it is troublesome hand washing, as previously recommended, is the readiest way of stamping it out. Before uprooting the Vines in a house to be re-planted, it is customary to obtain as much fruit from them as possible early in the season, cutting and bottling it when ready. Then remove the Vines and old border, and clean the house. Examine the drainage, and where out of order make it good, drainage being an important item as regards Vine culture. The border should be 3 ft. in depth, and 6 ft. in width will be sufficient the first year. Inside run a turf wall parallel with the house, and in front of this fill in with a good sound mixture of turfy loam, lime *débris*, charcoal, and crushed bones, well enriched with cow manure, filling up the vacant space behind the turf wall with leaves and stable litter, which will lead the roots inwards the first season, and increase their number. The outside border need not be renewed the first year. Vines struck from eyes this season are the best to plant. After they have made 2 ft. of growth plant them out, simply extricating the points of the roots, but allowing the balls to remain entire. After pressing the soil gently all round them, water with tepid water, and cover up with cow manure to prevent evaporation. With good treatment the Vines will become sufficiently strong to carry twelve pounds of Grapes next year without injuring them. Muscats will have got over their setting process; remove all bunches not intended to remain, and commence thinning the berries as soon as they begin to swell. Tie in carefully and neatly when danger of snapping at the neck is over. Maintain good leafage, but prevent over-crowding, retaining main leaves in preference to laterals. Ventilate early and freely in fine weather, taking all duo advantage of sun-heat when shutting up, and giving a little fresh air at dusk. Immediately after thinning give the border a good watering. At this stage mildew generally makes its appearance; where it is likely to be

destructive break up the surface of border, and add to it a little fresh dry soil and charcoal, painting the pipes with sulphur and lime. Allow the steaming troughs to become dry, and maintain a brisk healthy atmosphere. Attend to the tying, stopping, and removing of laterals in later houses; remove before they come into bloom all but one bunch on each shoot.

Pines.—Those swelling rapidly should be examined weekly, in order to see if they want water, which ought to be given at a temperature of from 85° to 90°, using guano in moderation at every watering. Daring cold weather hard forcing is necessary; but its ill effects should be counteracted by keeping the tan-beds and all available surfaces well damped. Only dow overhead in the afternoon, shutting up early with sun-heat, the night temperature should not fall below 70°, but when cold 65° are better for the plants. Shift young stock on as the pots become full of roots, 11-in. and 12-in. pots being sufficiently large for them. If the sunshine be bright after potting, shade slightly in the middle of the day for a fortnight; the roots will then be getting established in the new compost, and the shading may be removed by degrees.—J. HUNTER.

Kitchen Garden.

Another spell of wintry weather has again retarded operations in this department, and work in consequence having been delayed, the most unceasing perseverance will be requisite to bring up arrears. Our climate is such that the longest growing season is by far too short for the full maturation of some kinds of vegetables, and now that the sowing of seeds is so backward, of necessity the growing season must be brief; every means should therefore be used to promote rapid growth amongst such crops as Parsnips, Carrots, and Onions. As soon as the lines of the seedlings can be discerned, if the weather be favourable, run the hoe through them, and repeat the operation at frequent intervals. The ground being then kept open, the heat of the sun acts more quickly and powerfully upon it, to the great benefit of the crops, whilst, by such frequent surface-stirrings, the growth of weeds is prevented. Another means of promoting growth is to thin out all superfluous plants directly they are large enough to handle, which operation prevents a check being given to those that are to remain. In thinning Parsnips, they should not be left closer together than 6 in., Onions 4 in., Carrots (the large varieties) 5 in., the smaller kinds, such as Intermediat, 4 in.; of course, the short kinds, such as French Horn, if sown thinly, need not be thinned, only by being drawn for use. The advantage of sowing all vegetable seeds in drills will thus be seen, viz., the great facility afforded of cleaning and thinning them during their growth; and one would imagine that such advantages would be apparent to all, and induce them to adopt the plan rather than sowing broadcast; yet it is astonishing with what persistency some people cling to old customs, not taking into account the drawbacks such customs frequently entail. However, at the present day, a spirit of inquiry is abroad amongst gardeners and amateurs, and though, as a rule, all are prepared to reciprocate each other's ideas, yet, happily a spirit of independence exists, and each one has sufficient daring to think for himself, let "custom say what it likes." The first batch of Peas will be fast advancing to the flowering stage, and Peas may be gathered a few days earlier by pinching out the points of the haulm—a process we would not recommend, except when earliness is of paramount consideration. Earth up and stake successional sowings; the plants should always be staked as soon as they are 3 or 4 in. high—first, because less injury is caused to the roots by an early insertion of them; and, secondly, if the Peas once get out of the perpendicular, it is difficult to induce them to take kindly to the stakes. None of the varieties are germinating successfully this season; quite a third of ours have rotted in the ground, and, therefore, future sowings will be sown much thicker. The weather last autumn was very unfavourable for the Pea harvest, as also for most other kinds of seeds; hence the seedsman should be held harmless of blame should this season's growth of Peas be somewhat indifferant. A good breadth of French Beans should now be sown; for this early sowing a warm southern aspect should be selected, and the soil should be deep and well enriched with thoroughly decayed manure. The drills should not be less than 2 ft. asunder, sowing the Beans thinly, and when they are 2 in. or 3 in. high, thin them out to 6 in. apart in the row. In cold localities and situations, it is better not to risk the loss of the crop through frost by sowing too early; under such circumstances it is best to sow in shallow boxes, and grow under the protection of glass, transplanting them to the open ground as soon as danger from frost is past. The transplantation is always successful if the soil in which they are sown be composed of leaf or vegetable mould, as a profusion of roots is always made, and when lifted this kind of soil adheres well to them. If Cauliflower plants that were wintered under hand-lights manifest the slightest tendency to "button," pull them up forthwith, and, as a preventive to the remainder, give them a water-

ing with liquid manure; this will have a tendency to excite growth, and probably hinder any further premature flowering. It is time that all the autumn-sown plants were out, and a small quantity of those sown in heat in February may also now be planted out. Sow Veitch's Autumn Giant Cauliflower for succession; we never sow any other kind after this date. With us Brussels Sprouts are a most important crop, and as we always aim at having them at least 4 ft. high in the stems, they are already planted out, and to those who have never attempted such early culture we strongly recommend a trial; they are planted in deep drills 2 ft. 6 in. apart, on land that has been deeply trenched, and the Sprouts obtained are more like small Coleworts than ordinary Brussels Sprouts. Other kinds of Cabbages, particularly Coleworts, may now be planted if ground can be had for the purpose. Many other kinds of seeds may be sown, and plants placed out for succession, to name which would be but a repetition of former notes.—W. WILDSMITH, *Heckfield*.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

APRIL 19TH.

At this meeting the principal subjects of interest consisted of a well-bloomed collection of pot Roses from Messrs. W. Paul & Son, of Waltham Cross, and effective groups of new and rare plants from Messrs. Veitch & Sons and Mr. B. S. Williams. Attention was directed to some interesting experiments in Potato-grafting, which had been carried out by Mr. W. Maule, of Bristol, in order to counteract, if possible, the ravages of the Potato disease. In one of these experiments, which was illustrated by a photograph, a small piece of a Potato-stem had been grafted on a plant of the common Bitter Sweet (*Solanum Dulcamara*), the result being that the scion grew, and that tubers closely resembling Potatoes were produced from the roots of the Bitter Sweet stock. It thus seems possible to obtain graft hybrids, as has been previously asserted by Mr. Fenn and other Potato-growers, the result in this case being analogous to that of *Cytisus purpurascens*, which is said to have been originated by grafting *C. purpureus* on the *Laburnum*, the characteristic colours of the two parent plants being frequently blended in the same cluster produced by the offspring.

First-class Certificates.—These were awarded to the following new and rare plants:—

Pelargonium zonale var. Vanessa (W. Paul).—A robust and beautiful kind, having dark-zoned foliage and stout trusses of well-formed vivid orange-scarlet flowers, on which is a delicate flush of lilac. The individual flowers are large and of great substance, making it a welcome addition to kinds suitable alike for pot and out-door culture.

Phyllanthus roseus pictus (Veitch).—A graceful slender-branching shrub, with the habit of a Snowberry; its leaves, which are oval, are of a dead green colour, blotched and splashed with creamy-white and rose, the youngest leaflets being of a dull vermilion tint; it is a handsome ornamental-foliaged stove shrub.

Auricula Bessie Ray (Turner).—An effective profuse-flowering Alpine, having a pure and conspicuous yellow paste, surrounded by a velvet-like crimson border colour.

Auricula Alexander Meiklejohn (Douglas).—This is one of the best of the grey-edged class. It has a well-formed, clear, yellow eye paste-white and very dense, and the ground colour nearly black. Its truss, which is compact, is borne well above the leaves, and altogether it is a most desirable variety.

Auricula Slough Rival (Turner).—A strong-growing Alpine, having bright green leaves and large trusses of velvet flowers; paste ample, and of a soft yellow colour, the outer edge being of a deep velvety-purple margined with pure or blue. It is in the way of *A. conspiciua*, and well deserves culture.

Croton Macafeanum (Veitch).—A robust and effective variety, having broadly-oblong deep green leaves irregularly blotched with golden-yellow. It somewhat resembles *C. Hookeri*, but is much more effective, being one of the largest-leaved forms in the whole genus.

Miscellaneous Subjects.—Messrs. Veitch contributed a choice group of new and rare plants, among which we remarked a superb variety of *Dendrobium densiflorum*, bearing one of the most perfect spikes we have ever seen on a plant of this kind. In the same group was an example of the new *Thalassopsis Mannii* bearing a seven-flowered spike, and several choice and effective new *Crotons*, the best of which were *C. Disraeli*, with halberd-shaped or trilobed leaves; *C. Mooreanum*; and *C. Macafeanum*, a kind to which a first-class certificate was awarded. A hardy bulbous plant named *Chlidanthus fragrans*, a native of Buenos Ayres, was also shown by Messrs. Veitch. It had yellow Hemerocallis-like flowers, and bright green grassy foliage, and was deliciously fragrant. A very beautiful *Calanthe*, named *C. vestita ignea* oculata, came from Sir Trevor Lawrence's collection, the spike being nearly 4 ft. in length and furnished with twenty-two flowers, rather larger than those of the typical *C. vestita*, and of a creamy white colour with a vivid orange eye. Mr. Roberts, gardener to Mr. W. Terry, of Peterborough House, Fulham, sent two well-flowered plants of *Dendrobium chrysothorum*, each bearing ten or twelve spikes of golden yellow orange-lipped flowers. Mr. B.

S. Williams furnished an effective group of new Ferns, succulent, and flowering plants, all in excellent condition. Sir G. Macleay sent from Rome two examples of the Bee Orchis in flower. Mr. Parker, of Tooting, contributed a basketful of the double variety of *Primula acaulis umbellifera*, a kind with lilac flowers, also cut blooms of *Rhododendron magniflorum*, a kind which has large pure white flowers delicately scented. Mr. R. Dean furnished a plant and also cut flowers of the old double-yellow sweet-scented *Auricula*, besides a group of white, lilac, and magenta forms of *Primula corioides*. Mr. Croucher, gardener to Mr. Peacock, sent a graceful little specimen of the old *Xylophylla falcata*, about 18 in. in height, nearly every glossy green leaf of which was fringed with pale reddish flowers; the terminal leaflets (phyllodia) of this *Xylophylla* are much longer and more slender than the lateral ones, thus giving a pendent look to the plant, which for stove or dinner-table decoration deserves attention. Mr. Ollerhead, gardener to Sir H. Peek, Bart., Wimbledon House, showed a fine variety of *Dendrobium litiflorum*, bearing twenty large richly-coloured flowers on a long slender pseudo-bulb. This plant has been exhibited at one or two previous meetings, and apart from its beauty and showy habit, its flowers last much longer than those of most other *Dendrobies*. From the same exhibitor also came a well-bloomed plant of the old *D. densiflorum*, a small plant of *Masdevallia Veitchii*, and an example of the long-tailed Lady's Slipper. Messrs. William Paul & Son sent, as has been already stated, a large and effective group of choice pot Roses, remarkably well flowered. Among them we noticed *Therese Loth*, a soft, rosy Tea-scented variety, with smooth shell-like petals, delicately tinted; *Capitan Christy*, *Madame Urschbill*, and many others. Among the Tea-scented varieties we remarked the old *Souvenir d'un Ami*, *Madame Willermors*, *Madame Margottin*, and others, all valuable kinds for furnishing early cut flowers. The Hon. and Rev. T. Boswell showed a very effective group of cut *Rhododendron* blooms, among which were two new seedlings of considerable merit, a white one named *Meme*, and a delicate rosy one, named *Rose of Lamoran*, both fine kinds. An attractive collection of *Camellia* blooms, out from plants growing in the open air, was furnished by Mr. John Allen, gardener to Viscount Palmouth, at Tregothnan, in Cornwall. Mr. Allen, gardener to Sir R. Sheffield, Normandy Park, Brigg, sent four plants of a new broadly-acuminate-leaved *Iris*, named *I. Alleni*. It appears to be of robust habit, and may be of service in bedding arrangements.

Fruit and Vegetables.—Mr. Sidney Ford, of Leonards Lee, Horsham, showed a select collection of Apples in admirable condition, the varieties being *Petworth Nonpareil*, *Prong's Pippin*—a local name for a small rosy fruit of excellent quality—*Pine-apple Pippin*, a large finely-shaped fruit; *Poor Man's Profit*, an excellent culinary kind in the way of the better known *Dumelow's* seedlings, or *Wellington*, *New Rock Pippin*, and *Reinette Grise*. The same exhibitor also sent two brace of blasters' *Prolific* Cucumber, a handsome dark-green kind of excellent flavour. Mr. John Pottle, of Tooting, Sandbourne Hall, Wickham Market, showed six specimens of a new Cabbage, named *Broccoli*, a pale-leaved form of hearting Cabbage, having a small head of *Broccoli* inside. It was suggested that it may have been the result of a cross between the *Broccoli* and the Cabbage, being exactly intermediate between both of these esculents.

NOTES AND QUESTIONS—VARIOUS.

Hardy Spring Flowers.—You have not named among these the variegated *Symphytium*. I think it one of the very best of plants for a spring border; not for its flowers, but its leaves. It is a very striking plant at all times, but it is especially handsome in spring, when the leaves are small and the whole plant compact.—H. N. ELLIOTT, *Bilton Vicarage*.

Heating by Candles.—In some of the late fruit houses at Gunnersbury, where there is no heating apparatus, candles are employed to keep the houses from getting too low in temperature in very severe nights in spring. The candles are inserted in pots of sand three in each pot. A single line of the pots placed in a narrow row, at intervals of a few feet suffices to raise the temperature.—S. V.

Camellias out-of-Doors.—There is a common idea that it is almost useless to attempt the growth of *Camellias* out-of-doors; that they will live, but not flower. Last year I planted out two small plants, one against an east wall, and the other against a north wall. They were planted out in May, and formed flower-buds in the usual way. The plant against the east wall shed its buds in January; but that against the north wall has flowered satisfactorily. This may give a hint to others.—H. N. ELLIOTT, *Bilton Vicarage*.

Rooks and Rookeries.—After many years of vacillation and uncertainty, the rooks daily feeding and hovering about the trees surrounding my house have at last been watched. They commenced building one or two nests in the autumn, which were soon destroyed; early in March they again built three nests, one of which was blown down, and soon rebuilt. I have noticed in a number of new rookeries in this neighbourhood that they always commence with three nests. In some rookeries, instead of building the nests, they consist of the same number. (Can any of your readers tell me whether this is invariably the case?)—GEORGE MAW, *Benthall Hall, Brossley*.

Another Effort.—By an arrangement with Her Majesty's Commissioners the sum of £5000 has been made over to the Royal Horticultural Society on the security of the Commissioners, and by the end of this week every debt owing by the Society on the 31st December last will be paid, and the new medals and tradesmen's bills of every kind. The recent proposal to teach horticulture practically to amateurs and others has, we hear, been abandoned.

A Green Currant.—The Currant seen by "P." (see p. 380) in a garden in Norway, may perhaps be found in England. I recollect seeing it in a nursery in Lancashire forty years ago, where it was known as the "Red Currant Currant." It is almost certainly very little known, as I never heard of it afterwards.—THOS. WILLIAMS, *Ormskirk*.

"This is an art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES ON PRUNING CERTAIN EVERGREENS.

By JAMES M'NAB, Royal Botanical Garden, Edinburgh.

EVERGREENS are a class of plants the cultivation of which cannot be too generally adopted or recommended, and perhaps no temperate country is better suited for their culture than Britain. There are, however, certain peculiarities attending the cultivation of some evergreen shrubs which ought to be more generally known than they are. In newly laid-out places Evergreens are mostly mixed up with deciduous trees. At first all go on well together; in time, however, the trees, from want of proper and timely pruning, become close, and the Evergreens, deprived of the requisite amount of air, get drawn up, and many of them finally succumb. In such situations, if the deciduous trees be carefully thinned and pruned, and fresh soil occasionally laid over the roots of the Evergreens, they will go on annually improving—that is, if air have free admission, and attention be paid to the surface-dressing just alluded to. It is often observed how well some Evergreens thrive when in close proximity to the stems and roots of deciduous trees; some with which I am acquainted have grown on together for fifty or sixty years without any very bad effects being produced, which would not have been the case if air and occasional surfacing had not been attended to. If young Evergreens be planted on ground already occupied by deciduous trees, even although large pits are prepared for them, the roots of the existing trees will soon find their way into the newly turned up earth, to the ultimate injury of the Evergreens placed there. Annual branch, or rather twig, pruning has a wonderful effect at times in protecting large evergreen shrubs, whether exposed or in close proximity to trees. The branches of many kinds here are operated on annually to keep them within bounds, such as Evergreen Oaks, Portugal and Common Laurels, Sweet Bays, Hollies, and others. Such shrubs regularly pruned into a hemispherical shape with the knife, withstood the severe winter of 1860-61, while many unpruned specimens of the same kinds standing close beside them were either totally or partially destroyed. The saving of the pruned shrubs I attributed to the density of the surface twigs and foliage retaining the weight of snow which lay heavily upon them, when the thermometer fell several degrees below zero, and snow was on the ground nearly 2 ft. in depth. During this time many unpruned specimens were killed down to the snow-line, the branches, and in many cases the exposed parts of the stem, being split up with the frost, and the stems in many instances had to be cut down to within 3 ft. or 4 ft. of the ground, giving them something of the shape of the annexed figure. After being cut, the surface of the ground, extending as far as the original branches, was covered with a good coating of leaf-mould, &c. Many of the shrubs thus operated on during the spring of 1861 are now finely-formed specimens, and owing to the annual twig-pruning to which many of them are subjected, they may go on uninjured for many years to come. Portugal Laurels, cut down either from the effects of frost or from being large and rampant, may after a year or two be transplanted with success, which would rarely be the case if transplanted unpruned, unless great care and much expense were incurred in the operation. I have seen stumps of mutilated Portugal Laurels thirty and forty years old removed with safety; many of these are now thriving, shapely plants, and for this end care should be taken to give them a good outline when they are being cut down. The success, too, attending the removal of such large masses is greatly facilitated by having their roots cut round when the

Laurel cut back.

tops are shortened. When a new shrubbery is in course of formation the introduction of a few of these cut down stumps into it gives the place an aged appearance, and the growth of such plants is greatly increased by having the ground trenched before they are planted. During the severe winter just alluded to instances came under my observation which do not exactly agree with the foregoing remarks. They have reference to three injured hedges, and the circumstances attending their injury ought to be recorded. One, consisting of Holly, was about thirty-two years of age, 60 yards long, and 7 ft. high. This was annually clipped, but was growing in rather a damp situation. It was killed down to the snow-line, while of eight of the leaders left in this hedge, and standing at regular distances apart with large conical tops about 12 ft. high each, not one suffered. The hedge in question, with the exception of the turrets or leaders, was afterwards cut down to within 18 in. of the ground, and after being well "breasted" in on both sides, and the ground surfaced over with good soil, it is now as tall and as good as ever it was, and is still furnished with its original turrets or leaders. How the frost affected the main portion and not the elevated leaders remains a mystery. A Portugal Laurel hedge, upwards of fifty years old, although annually clipped, and growing in a damp subsoil, also suffered severely during 1860-61. It was cut down to within 30 in. of the ground, and breasted on both sides, the surface being afterwards coated with good soil. This hedge grew freely, and is now perfectly good. A portion of this Portugal Laurel hedge was transplanted when covered with young growths, about three years after being cut down. The portion removed is now as dense and as healthy as the portion not lifted, notwithstanding that the roots were not cut, as recommended for Portugal Laurels standing singly. Another case was that of a Holly hedge, about 200 yards in length, standing in a dry situation along the north side of a high boundary wall; this hedge, which averaged 10 ft. in height, had not been clipped for many years, and it suffered severely during the winter of 1860-61. After, however, being well cut down and breasted in, and otherwise treated like the others, it is now growing freely, while a Holly hedge 160 yards long, running parallel with and standing within 60 ft. of the one killed, but with a full southern exposure, was not injured in the least, although 10 ft. high. The wood of the former, from having a northern aspect, and quite out of the reach of the sun, was not sufficiently ripened to stand the severe frost which was experienced at the time. During the severe winter of 1860-61, many Deodars were injured in the Botanic Garden, those which escaped unhurt being the "branch-pointed" specimens, the cutting off the points of the branches, like the Portugal Laurels already alluded to preventing their being bent down with snow, of which there was at the time a heavy fall; while almost all the unpruned specimens, with the exception of one growing in a damp situation, were more or less cut to the ground, and several were killed outright. The pruning of the Deodar, as well as of many other Coniferous trees, has not in every instance been attended with success; but failure in all the cases investigated has resulted almost entirely from the neglect to put some covering compost over the surface of the ground, extending from the stem to the extreme points of the roots, so as to prevent the sun shining on the surface-roots during summer, or frost reaching them in winter. It seems to make little difference at what season of the year the branches of Deodars are pruned. I have performed the operation at all times without their sustaining any injury, some being cut pretty close to the main stem, so as to give them a conical shape. This form in the case of Deodars is not, however, always to be recommended, although in some instances it is required and even practised, particularly in some of our suburban cemeteries, where such plants often spread over a considerable extent of surface, and often over places which they are not intended to occupy. If damage be sustained by the cutting of such plants, the operators have themselves to blame through not attending to the instructions which have been given on the subject. There are many people who maintain that Deodars and other Coniferous shrubs should not be pruned. In many cases, however, and one of these I have just mentioned, pruning is absolutely necessary; and I may say that I have never yet seen a Deodar injured

in a high and dry situation by a free use of the knife, provided proper attention has been paid to it after it was operated upon.

ORCHIDS—BASKETS v. POTS.

The ordinary flower-pot so generally in use for Orchid culture is by no means all that could be desired for that purpose; it seems unreasonable to put epiphytal Orchids—which grow naturally on the branches of trees, and have roots requiring almost as much air as the leaves and stems themselves—into pots so constructed as to exclude all air from the roots, except the small quantity that can reach them from the top and the bottom of the pot. It is from this cause that many Orchids are found so difficult to rear successfully in pots, not so much during the growing season, for at that time the roots are young, and capable of imbibing the moisture; but when the plants are at rest, the roots should also be at rest; consequently, those grown in pots are more liable to be affected by any oversight or mismanagement, such as too much heat, too much water, or getting under drip; and many Orchids capable of retaining their roots in a healthy condition for years if grown in baskets, on rafts, or on blocks, are annually lost when grown in pots. My conviction that epiphytal, and even terrestrial, Orchids are more safely cultivated in baskets or on blocks than in pots was amply confirmed in the following instance, which came under my personal notice last year:—A gentleman in the neighbourhood of London commenced the culture of Orchids in the only available house he had, a small ornamental conservatory adjoining the drawing-room; he purchased from time to time such Orchids as he fancied without any reference to their being hot or cool house varieties; the plants in baskets or on blocks were suspended from the roof, and those in pots were placed on the stage round the house. We frequently had conversations about Orchids, in the course of one of which he complained that his plants in pots did not thrive well. I then informed him that I always considered such subjects to be much safer in baskets than in pots, mentioning cork as a good material of which to make the baskets. About three months after I paid him another visit, and was surprised to find nearly all the Orchids (terrestrial and epiphytal) either in cork baskets or on blocks, suspended from the roof and all in the best possible condition. It was curious to see the old *Phajus grandifolius* in full bloom and several of the *Cypripediums* also in flower in baskets, two or three fine plants of *Zygopetalum crinitum* on blocks, *Odontoglossum Roezli* in flower, *O. Alexandræ*, *O. Pescatorei*, and *O. triumphantis*; *Calanthe veratrifolia*, *Maxillaria venusta*, most of the rarer *Dendrobies*, and many others, all in baskets or on blocks. I afterwards had the pleasure of seeing many of them in flower, and always found them in good health. I do not attribute the total success of their healthy development to the fact of the Orchids having been placed in baskets, for they might have succeeded tolerably well if planted in ordinary pots and suspended in the same way as the baskets, but I feel confident that if they had been left on the stage they would have entirely failed, while the appearance of the hanging baskets added materially to the decorative beauty of the conservatory. Some object to baskets because they are liable to rot, and others say that, although the plants do well in them, when one wants to shift them into those of a larger size, the roots are so interlaced in the old baskets as to render it difficult to remove them without serious injury. With respect to the first objection, imperfect ventilation has often been found to be the cause of the baskets rotting, but it is important to have them made of durable wood, such as Teak or Oak; and when so constructed they last a considerable time. There is also a very good kind of Orchid basket made of terra-cotta, which, although rather heavy, answers the purpose admirably. In shifting the plants no difficulty will be found if the wires of the old basket be drawn out and removed a piece at a time, making use of a thin-bladed knife to remove the clinging roots. The great argument in favour of baskets, rafts, or blocks is, that while there are a great many epiphytal Orchids that really will not grow in pots for any length of time, all succeed if grown in baskets; therefore those having plants not thriving in pots should turn them out, wash the roots, and place them in baskets.

In favour of the flower-pot, which it is not desirable to dispense with altogether, we may urge that it is cheap and durable, it is to be obtained either in town or country in quantity, and it does not harbour insects; it is also necessary for such terrestrial Orchids as *Cypripediums*, *Calanthes*, *Phajus*, &c., which we shall deal with shortly, and a great number of the stronger-growing epiphytes will do well in pots if the following instructions be attended to:—In the first place, see that the pots intended to receive the plants are clean, then have them crocked to within one-third of the top (except in case of such plants having long roots, as the *Vandas*, &c., when the lower roots must be put in first and the crocks afterwards), after which place a layer of *Sphagnum Moss* on the top of the crocks to keep the drainage open. Good fibry peat without soil is the best preservative for the roots, and this may be used by itself for *Cattleyas*, *Lælias*, and most *Oncidium*s, and with the addition of fresh *Sphagnum Moss* for *Odontoglossum*s, *Masdevallias*, &c.; always have the peat broken with the hand, and in using it take the large and small pieces for the large and small pots respectively, being careful not to press it in too tightly, so as to impede the action of the air and the free passage of water. But the most important matter is to keep the plants well above the rims of the pots, so that when the plants send forth new roots, they may not be forced to descend into the pot, but may spread themselves over the surface or just below it, and thus receive the benefit of the air so necessary to their proper development. The stages, if not of trellis-work, should be covered with coarse shell-gravel, or some similar material to allow of the free passage of water through the pots; and if the stage be flat, all but the front row of plants should be arranged on inverted pots. It is also desirable to move the plants frequently, and have the pots washed, as if they be allowed to get very green, they will deteriorate the air of the house. By attending to these instructions, and by carefully regulating the heat and air, epiphytal Orchids may be grown in pots with every probability of success.

JAMES O'BRIEN.

[GROWING CALCEOLARIAS FOR SEED.

PLANTS intended to bear seed should be grown without check from first to last; and if be is a question of gathering as much seed as possible from them, they should be grown for that purpose alone, and not employed for general decorative purposes, nor be pushed into flower before their natural season, which, in the case of the *Calceolaria*, is May and June. Though these instructions will be serviceable to people who have plants coming into flower this season, we must begin at the beginning in giving the general routine of culture. Sow the seeds in the first or second week in August, in a shallow pan of very fine light soil; barely cover them out of sight, put a pane of glass on the pan and place it in a cold pit within 6 in. of the glass, taking care it is set perfectly level, and keep the soil uniformly moist till the seedlings are fairly up. Then remove the pane of glass and attend more particularly to watering; do not keep the soil sour and claggy, but never let it get dry. When the plants are fit to handle with the finger and thumb prick them off 1 in. apart in properly-drained pans or boxes 4 in. deep, using a compost of peat or leaf-mould and loam put through a half-inch sieve and plenty of river or silver sand. Restore them again to the cold pit or put them in a cold greenhouse where the temperature is never below 40° or above 50° in winter; keep them away from hot pipes, water regularly as before, and keep them close to the light. By midwinter they will be getting crowded, and must be boxed off again, for growing them on in boxes as long as possible is half the secret of success. This time lift them with good little balls to their roots, and plant them 2 in. or more asunder, using the same kind of compost as before, with a little well-rotted cow or decayed hotted manure, all sifted and made fine and workable. This shift will serve them till February, and if they be only attended to in the way of watering and not forced by fire-heat, they will be broad, dwarf, and vigorous, showing no disposition to flower prematurely, and will be free from green fly. I never had occasion to fumigate them, at least up to this stage, and seldom at any other time. This last shift, which should be given before the middle of February, will be the final

one. Prepare the requisite number of 9-in. and 10-in. pots by cleaning and crocking them carefully; then get ready a compost the same as before, only not sifted, but chopped as finely as possible with the spade and well separated, not forgetting the rotten manure and the sand. Lift the plants out of the boxes with good balls—an easy matter—and transfer the weaker-looking ones to the 9-in. and the stronger ones to the 10-in. pots, filling in carefully so as not to injure the broad and tender leaves; pot rather loosely, trusting to settling the soil well about the roots by a thump on the bench and a shake rather than ramming, and leave half an inch at least for water. If any plants show a flower-stem, pinch it close out. Set the plants closely together to prevent evaporation from the sides of the pots in a light span-roofed-house or lean-to greenhouse, and as near to the glass as possible. From this time the plants, being in pots, need more care, everything depending on copious but careful waterings, abundance of light and air, and coolness: avoid fire-heat as much as possible. As spring advances the plants will rapidly increase in size, and by April they will be throwing up their flowers, and will need staking. The simplest plan is just to put three or four sticks round the pot and run a piece of matting round them. If saving as much seed as possible be the object, keep all the plants; but if selection be aimed at, then save only those which combine a dwarf, stocky habit, with large, full, well-coloured flowers. Having made your selection, give the plants what room is required, to prevent crowding, but no more. Keep the house cool and airy night and day, and sprinkle plenty of water among the pots and on the floor in sunny weather. Have a small camel's hair brush, and when the flowers begin to open just touch the stamens and stigma slightly in order to fertilise them, and continue this operation at least two or three times a week about noon, till the last flowers are out. This use of the brush does not take much time, as a boy can go over hundreds of plants in an hour, and it greatly helps the setting process—in fact, it is essential to ensure a good harvest. The seed-pods soon begin to fill and get plump, and shortly after the first flowers are set it is necessary to look over the plants daily and pick off all the pods which are observed to be changing to a brown colour, otherwise they will burst and the seed will be lost. Gather the seed on a flat tray, and leave it in a quiet corner of the house to dry, but take care that it is not blown away by the wind. When all is gathered and dried, rub it through a fine sieve to clear it of husks, and afterwards shake the seed out on a sheet of paper, blow the dust out of it, store it in packets, and keep it dry. *Calceolaria* seed is exceedingly minute, and it takes a large quantity of it to make an ounce, but I have saved it at the rate of about an ounce to fifty plants, under not very favourable circumstances.

CHEF.

BULB-BEDS CARPETED WITH SAXIFRAGES.

MR. WARE'S plan of planting bulbs among Mossy Saxifrages I have strenuously advocated for some years, and practised it myself. It is only a modification of the system of planting Snowdrops, Crocuses, and Daffodils on lawns in grass, and whoever may have seen Hyacinths in an ordinary bed and in one mossed over with Saxifrages would at once be struck with the beauty of the latter as compared with the former. There is generally a paucity of foliage in connection with our choice early bulbs, and it seems a pity to see such beautiful blossoms resting on the bare earth; neither do the colours of these early flowers appear to advantage when lying on the ground, but they are beautifully set off by a carpet of Saxifrage. The charming early *Iris reticulata* appears more benefited by such treatment than any other early bulb with which I am acquainted, owing to its very sparse foliage. I have seen beds of choice early bulbs covered over with Moss; but what is dead Moss compared with living verdure? I grow, I think, above fifty of the Mossy Saxifrages, and have somewhere pointed out their utility as winter plants for filling up beds otherwise bare, for which purpose they are simply charming, varying as they do from the emerald green of *S. viracens* to the pea-green of many of the others. Some judgment and a knowledge of Saxifrages are requisite in order to properly adapt the carpet to the bulbs. *Scilla præcox*, or *albrica*, would appear smothered among such Saxifrages as *hypnoides* or *incurata*; but it would appear as if lying on green velvet on such

kinds as *S. densa* or *greenlandica*, the latter being almost as flat as a Lichen, while stronger-growing kinds should be employed for such plants as Tulips and Hyacinths after the early bulbs are over. These fresh green beds, too, are no mean objects in summer, especially when edged with the silvery or encrusted kinds of Saxifrages, such as *pechinata* or *rosularis*.

THOS. WILLIAMS.

Bath Lodge, Ormskirk.

Transplanting Wild Flowers.—Allow me to inform "L. L. C." (see p. 380), that I do not think it is the wisest plan to transplant even wild flowers when in bloom, unless a good portion of the soil, Grass, &c., be removed with them, so as not to interfere much with their roots. If a check be given during the blooming period, the plants would very likely not recover before another season. Last May I cut with my pocket-knife from a pasture, with the Grass and soil surrounding it, a root of the common Speedwell (*Veronica officinalis*) just breaking into bloom. I folded the clump in Dock leaves, and in an hour or two planted it at the base of my Alpine rockery. It went on growing and blooming, seeming not to have suffered at all. I eventually cleared it of the Grass and weeds, and it is now about 1 ft. square, and will soon be a mass of bloom.—P. F. LEE.

Calla æthiopica for Church Decoration.—Few plants are better adapted for church decoration than this, especially at Easter, when white flowers are so much in demand. We have lately used it with excellent effect as a background to White Spiræas, Deutzias, Hyacinths, and Primulas, edged with *Pteris serrulata*. The trumpet-shaped flowers and fine foliage of the *Calla* contrast admirably with such plants as those just named, and near the font or springing from a cool bed of Ferns, *Callas* are the best plants that can be used. When cut, too, their spathes are very effective where bold and striking combinations are necessary. For altar decoration we used the largest *Calla* blooms, supported by a background of scarlet *Pelargoniums* and Fern leaves, and the effect was equally satisfactory both during the daytime and under artificial light.—JAS. GROOM *Henham*.

Coltsfoot Pushing through Asphalt.—About four or five years ago the platforms at our station here (Mitcham Junction) were laid down with a thick coating of asphalt. Nevertheless, such is the force of growth and endurance existing in the roots of the Coltsfoot (*Tussilago Farfara*) that every year it forces its way through the asphalt, despite the hardness of that material. The asphalt is pushed up into little hillocks, which gradually crack; very soon the young leaves make their appearance, and afterwards the whole plant. The common Thistle I have also noticed doing the same. Let any one take a cake of asphalt and try to push a stick through it; he will then be able to realise how great must be the vital force exerted by the plant-roots in question, which, by adding particle after particle to their structure, are enabled to upheave and displace such a hard compact material as asphalt.—HENRY A. WOOD, *Willow Lodge, Mitcham*.

Pinks Suitable for Forcing.—Not many years ago there were but a few varieties of Pinks that could be successfully forced into bloom in February or early in March, and these exceptional varieties consisted of one or two white-flowered kinds and the well-known *Anna Boleyn Pink*, the latter being a large showy highly fragrant kind, but having the serious defect of almost invariably bursting its pod. Mr. Dalton, of Bury St. Edmunds, an enthusiastic amateur florist, therefore resolved, if possible, to raise a Pink that would force without this defect; and he succeeded several years since in originating a highly-perfumed variety, with flowers of the same colour though somewhat smaller than those of *Anna Boleyn*, but possessing the advantage of a well-formed pod of such consistency as to put bursting out of the question. This was soon followed by a greatly improved variety, named *Plato*, both sorts being well adapted for forcing. Mr. Clarke, too, another Bury St. Edmunds amateur florist, succeeded in originating several useful varieties, the best of which have been named *Garibaldi*, *Devery Day*, and *Lord Lyons*. The last is quite a gem in its way, and one now well known and extensively grown; and the Floral Committee of the Royal Horticultural Society very properly bestowed upon it a first-class certificate some twelve months ago. From the same source we have also yet another superb variety, named *Duchess*, a kind which is in all respects a fitting companion for *Lord Lyons*. The flowers of this new sort are exceedingly fragrant, and their colour a delicate lilac-pink, with a darker blotch in the centre. Its petals are finely rounded; the individual blooms are large and full, and the pods are exceedingly strong and not at all likely to burst. This Pink is of vigorous habit, and is one which appears to be a profuse bloomer, and easily forced into flower.—P. GRIEVE, *Culford Hall*.

NOTES OF THE WEEK.

MANY of the Lilac bushes now look so weak in their too numerous branchlets that one cannot help thinking that the Continental practice of pruning the Lilac, so as to ensure strong flowering shoots, would often be desirable here. In French public gardens the Lilac is regularly pruned, *i.e.*, so thinned that strong flowering shoots take the place of the weak straggling crowd of branchlets.

A SINGULAR effect is now to be seen wherever strong and established tufts of the Giant Knotweed (*Polygonum cuspidatum*) are coming up. The great spotted shoots rush up in crowds to the height of a yard before breaking into leaf or branchlet. These were said to be edible, forming one of the many so-called substitutes for Asparagus. If of any use as an edible, what an immense yield might be looked for!

WITHOUT doubt the various kinds of Daffodils now in cultivation are the most valuable of all hardy flowers for our climate. No other flowers have withstood the snow, sleet, rains, high winds, and frosts as these have done. Some of the finest kinds seem, indeed, to take no notice of the weather, be it what it may. For weeks now gardens where these plants are fairly represented have been full of their beauty, and so they yet remain.

BRUGMANIA SANGUINEA, planted out in a greenhouse at Kew, is now in great beauty. It is 6 or 7 ft. high, and perhaps 10 ft. or more in diameter, and literally loaded with orange-red tubular flowers. We have seen this Brugmansia in the conservatory at Hatfield in equally good condition. Though a large-growing plant, no one need be afraid to plant it even in comparatively small houses, as it is rather improved than otherwise by being occasionally well cut back.

A BOTANIC Garden about twenty acres in extent has just been opened at Southport. In connection with it a museum has been erected containing collections in the various branches of natural history, the ontogeny of the neighbourhood being well represented. Geology has a department assigned to it, and the whole of the collections have been well arranged and classified.

MR. TURNER has sent us some of the Cox's Orange Pippin Apples alluded to last week. They were, when they arrived (on April 21st), perfect in colour, flavour, and texture, and without a wrinkle; Rib-stems, sent at the same time, were much shrivelled. They were both kept in a wine cellar, each fruit being wrapped in a bit of tissue paper. As we before remarked, the common notion of what a fruit-room probably ought to be is a mistake. Fruit-rooms, as generally made, are not suited for the long-keeping of late fruits. A good cellar under the garden-house or office will prove a great improvement on the ordinary fruit-room for the keeping of the finer kinds of fruits.

OVER 4,500,000 tons weight (about 1000 million gallons) of rain fell over Paris in twenty-nine days during the recent floods, and an examination of samples led to the estimate that nearly 9 tons of ammonia were washed down with it, containing sufficient nitrogen for a forest that would cover the whole of Paris. The question has often been raised whence plants get their nitrogen, and the above figures help to explain it. The rain was also estimated to contain about 88 tons of mineral substances, amongst them being globules of iron of meteoric origin.

AMONG hardy shrubs now in bloom, Magnolias of the *M. conspicua* type are now very beautiful in many London gardens, and the best forms of them deserve to be planted more extensively than they are. The orange-flowered *Berberis Darwinii* is also very effective both isolated and in masses at Kew, and in the Exotic Nursery at Tooting; one of the most beautiful of all spring-flowering trees is the *Pyrus Malus floribundus*, which is now one mass of delicate-rosy flowers and carmine-tipped buds. *Pyrus japonica cardinalis* is likewise a very choice and distinct form of the well known type from which it differs in bearing much larger flowers of a dark crimson-scarlet colour. *Cerasus Sieboldiana rosea* is also very pretty just now, as is likewise a weeping form of *C. Avium*, profusely covered with snow-white blossoms. Flowering shrubs, such as these, associated with the tender young leaves now everywhere opening, have a strikingly pretty effect, and should be planted much more profusely than they are.

We learn with much pleasure that the Pine-apple Place Nursery, one of the oldest in London, has been purchased by Messrs. E. G. Henderson & Son, of the Wellington Nurseries, St. John's Wood. This is one of the most famous of the great London nurseries, and which has lately passed through some vicissitudes, returns to the family possession of those who founded it many years ago. The two nurseries will, from the beginning of the coming year, be parts of one concern, and be under one management. It is fortunate that

such an establishment as Pine-apple Place falls into hands capable of making it again what it was before—one of the best-managed and most richly-stored of the great nursery gardens of London. We may add that the Pine-apple Nursery was founded by Mr. Andrew Henderson (grandfather of the present head of the house of the same name), whose eldest son is E. G. Henderson, the founder of the Wellington Nurseries, and who is now in his ninety-third year.

It is proposed to erect an aquarium and winter garden at Clifton, and a committee has been appointed with a view of obtaining a proper site.

MR. CHARLES DARWIN is said to be engaged on a new work on the comparative results of the cross-fertilisation and self-fertilisation of plants, which will contain a great mass of new observations.

SPIRÆA PALMATA is now brought out Covent Garden in excellent condition, the plants being forced in small pots, and thus treated form pyramids of fresh foliage, and tufted masses of bright rosy flowers.

MESSRS. JACKMAN'S exhibition of Clematises opens on Monday next in the Royal Botanic Gardens, Regent's Park, and will remain open for some weeks; a beautiful collection of these plants may be looked for, and it will also contain fairly well-grown plants of the newer kinds.

We are informed that arrangements are being made for holding the Nottingham and Midland Counties Rose Show and Horticultural Exhibition in the Arboretum, at Nottingham, on the 6th, 7th, 8th, and 10th July next, and that a liberal schedule of prizes is in course of preparation.

Orchids in Flower at Kew.—A plant of *Odontoglossum* *lave* bears two very good spikes, one of which is much branched and nearly 2 ft. in length. This species is not common in collections, and has greenish sepals and petals, barred with brown, the lips being white with a broad blotch of purple, where it is contracted in the middle. *Chysis bractescens* also bears three or four of its great wax-like flowers, each having a five-ridged yellow crest. This plant, like the last, is also rarely seen in perfection, but when well grown is one of the most chaste of all Orchids. The dwarf *Aerides japonicum* also bears a pendent spike of pale greenish purple-barred flowers, which are delicately perfumed. *Maxillaria luteo-alba* is also in excellent condition, a single specimen of it bearing some twenty or thirty yellow, white, and chocolate-coloured flowers resembling those of *M. picta* in shape, but much larger. Of all white-flowered Orchids perhaps *Ptilonota fragrans* deserves most notice on account of its exquisite Pine-apple-like perfume, which is most observable in the morning, but which is at no time entirely absent. A variety of *Phalopsis grandiflora* bears flowers measuring $4\frac{1}{2}$ in. across, but, apart from their extra size, the structure of the lip differs from that of any other variety with which we are acquainted; the terminal cirrhi being borne on a little stalk, which elevates their bases above the central blade of the lip.—B.

Apricot Trees and Spring Protection.—I was much interested in Mr. Groom's remarks (see p. 358) upon the protection of Apricot trees. My own opinion as regards coverings is very similar to his. I also agree with him in believing that it is a decided mistake to trust to any sort of coping, or to have young wood away from the wall. My experience has been as follows:—When I came here about eleven years ago, I found a south-west wall covered with unfruitful and not by any means healthy Apricot trees. I obtained permission to lift them. Finding that the roots had penetrated into clay of the worst description, I had a large quantity of the sub-soil removed and a good layer of concrete put in. I then filled up again with suitably-prepared soil, and closely pruned the re-planted trees. With blinds for protection, our crops are all that can be desired. Our prospects this year, in spite of the very adverse weather which we have experienced, and repeated frosts of 9° and 10° intensity, are more favourable than in any previous year. I may perhaps mention that fruit prospects generally in this neighbourhood are very good, Pears being almost the only exception.—J. ALLAN, *Ashurst Park, Kent.*

Dana's Hovey Pear in Sussex.—The fruit is small and very handsome, wonderfully juicy and sweet, with an aroma of extraordinary richness. It is a veritable sweetmeat, and its value is all the greater from the fact of its keeping good quite six weeks after it is ripe. Fruit, which was gathered on October 25th and was quite ripe on November 29th, was pronounced delicious on January 9th. I should add, that the tree is one of the Sawbridgeworth "double-worked" specimens, which probably has some influence upon its fertility.—EDWARD LUCKHURST, in "Journal of Horticulture."

THE INDOOR GARDEN.

A NEW ODONTOGLOSSUM.

(*O. CIRRHOSUM*.)

THIS is without doubt the most beautiful *Odontoglossum* in the white purple-spotted group, of which *O. nævium* may be

Odontoglossum cirrhosum.

taken as the type; it is, however, abundantly distinct as a species—a fact worthy of notice—because now-a-days any trifling variation in size, colour, or time of flowering in the case of an Orchid, entitles it, in the opinion of some, to specific

Flower of *Odontoglossum cirrhosum* (two-thirds the natural size).

distinction, much to the perplexity of amateur cultivators. This *Odontoglossum* is, moreover, so chaste and beautiful that it will not disappoint the most fastidious, and cultivators may be able to form some idea of its size and attractiveness, when we state that it is just what the best variety of *Odontoglossum nævium majus* would be, if it could be got to produce from

fifteen to twenty flowers on a spike, the individual flowers of *O. cirrhosum* being fully twice the size of those of the large variety of *O. nævium*, and they have, in addition, some rich purplish-brown streaks at the base of the lip. These bright colours on a pure white ground constitute an agreeable addition to its beauty. Our illustrations show the general contour of the plant, and a single flower of it, the latter being only two-thirds the natural size. The column is white terminated by two long awns; hence the specific name, these being more conspicuous than similar appendages in its ally, *O. nævium*. The growth of *O. cirrhosum* is somewhat distinct, the leaved pseudo-bulbs being elevated on short creeping rhizomes, and the leaves, which are nearly strap-shaped and of 9 in. or 10 in. in length, being of a very dense glossy green. The spike, about 18 in. or more in height, is erect, but nodding towards the apex, so that the portion on which the flowers are borne is, as will be seen, gracefully arched. The plant appears to have been first discovered many years ago by Captain Hall in Ecuador, on the western slope of the Andes, at an elevation of 6000 ft., and it has since been found by Professor Jameson and the Brothers Klaboch, the last-named collectors having succeeded in obtaining some hundreds of plants of it in good condition. It appears to have flowered with Sir Trevor Lawrence and Mr. Spencer Brunton, of Beckenham, nearly simultaneously, but it was first exhibited by the last-named cultivator at the Royal Horticultural Society's Meeting which was held on the 5th inst., when it was unanimously awarded a first-class certificate. As to the merits of the plant there can be no two opinions; it is one of the most beautiful and chaste of all *Odontoglossums*, and one without which no collection can henceforth be considered complete. The plant is one of Mr. W. Bull's introductions. B.

PROPAGATION OF TUBEROUS-ROOTED BEGONIAS.

In most cases the want of success in propagating these arises not so much from their being difficult to strike, as from their being left until the plants are large enough to allow of the side-shoots being taken off for propagation without spoiling their effect as flowering plants. A *Begonia* of the *Boliviensis*, *Sedeni*, or *intermedia* class, when it becomes large, has no cuttings on it fit for propagation, every bit of growth being devoted to the production of flowers; true, a few cuttings may be obtained from the base of the plant, and these, by careful management, may be induced to root, but even if they do so they do not make sufficient bulb to carry them through the winter, and hence cultivators are often surprised on turning out the pots which had contained healthy little plants to find no bulbs. The cause of this is that the cuttings being taken from flowering plants had only established themselves sufficiently to enable them to fulfil their functions as flowering growth, and had not the time required to permit of their making bulbs, and the nearer the plants approach in habit to *B. Veitchii* the more particularly do these remarks apply to them. In the event of its being absolutely necessary (as in the case of a new variety) to take late cuttings, the evils of such a course are in a measure to be obviated by preventing the young plants from flowering, by keeping them growing as long as possible, and when they die down, by putting them away, not with the other bulbs but on a shelf in a cool-house, and giving them a little water from time to time during winter. The woody stems at the base of the cuttings will then gradually form bulbs, which will start into growth at the proper time, and they will become good flowering plants in due season. With reference to the propagation of three varieties, viz., *B. Veitchii*, *B. roseiflora* (or that which is usually sold for it, the beautiful variety originally sent out by Messrs. Veitch under that name being very scarce), and *B. Corail Rose*, the best way is to save some pods of seed when the plants are in flower to sow early the next spring, and thus obtain plants, some of which will probably flower the same year. There is no certain way by which the two first-named may be otherwise propagated, and as they come true from seed, any other means are scarcely worth a trial, *B. Corail Rose* might, perhaps, be raised from cuttings, but as cuttings are not easy to get, and as it comes tolerably true from seed

that is the better way. Owing to the varieties of the *B. Boliviana*, *Sedeni*, *Dr. Masters*, and *intermedia* class not coming true from seed, and when raised in that manner being usually very inferior to the parent plants, it is absolutely necessary to propagate them by means of cuttings, and the following way of doing this has been found to be simple and successful:—In spring, when the plants have grown from 4 to 6 in., get some good fibry yellow loam, break it up small with the hand, and mix it with about one-third its bulk of peat and silver sand; have some large thumb or small 60-sized pots crooked, and fill them with the prepared soil, which should be moderately moist, taking care not to press it too firmly; do not put sand on the tops of the pots, nor water them; next go over the plants, and with a sharp knife take off as many cuttings as can be spared just above the bulb; pull off the small green sheath that usually adheres to one or two of the lower joints, and if there be a leaf at the bottom joint, cut it off; then insert the cuttings, three or four in each pot, previously prepared, round the edges. They will root in almost any temperate shady place without a propagating frame, or even in the house where the cuttings were taken off, provided it be not too dry. But the plan which I adopt and consider the best is to put them under the middle stage on the bare earth, in a temperate moist house, where the sun's rays and the heat from the pipes cannot reach them, giving them no water, unless they show signs of flagging, until they are rooted. They soon make roots if taken at the proper time, and when in proper condition should be potted off singly and put back in the same place for a week or so, when they may be grown along with the general collection. Cuttings of these *Begonias* will also strike in the spring if inserted in Cocoa-nut fibre or tan in a gentle bottom-heat; but the former mode I have always found to be the best. Cultivators of these *Begonias* should bear in mind that although young plants of them like a little heat, the older and stronger ones do not require it, and that their proper place is the conservatory or cool house, where they will last much longer in bloom than they do in a warm house; indeed some of our neighbours who have sheltered gardens grow many varieties of them in the open ground in summer. JAMES O'BRIEN.

CULTURE OF THE DOUBLE CHINESE PRIMULA.

ALTHOUGH perhaps inferior to the single varieties in point of brilliancy of colour and general capability for effect, the double Chinese *Primula* possesses certain qualities which render it in some respects even superior to them. It is, without question, one of the most useful plants for the production of cut flowers in the winter; for this purpose, indeed, it is simply invaluable; in fact, a bouquet which is required to be composed of flowers of a chaste and delicate character, can hardly be considered complete without it. One of its greatest merits consists, perhaps, in its ability to keep up a continuous successional supply of bloom during that very dull stagnant period of the year when cut flowers are so much in demand and so difficult to produce. A few large well-grown specimens kept growing in a temperate house will furnish bloom during the winter, and, as the individual flowers last for a long time, and do not easily become shattered, they are as serviceable for the embellishment of vases, epergnes, &c., as for bouquets. A glance into Covent Garden Market will serve to give any one an approximate idea of how much this flower is in demand, and to what an extent it is employed. Some few years ago there were but two or three varieties of double *Primulas*; but now that some really novel and fine varieties have been raised, their culture has been rendered more attractive. Owing perhaps to the fact of their being increased by means of cuttings only, their culture has never become quite so popular as might have been expected. Although fairly easy of propagation, many cultivators do not appear to obtain much success in their attempts to increase their stock, which oftentimes gradually dwindles, and their culture is relinquished under the erroneous impression that they are naturally miffy and delicate, and therefore unsuited to general requirements. The greater part of these failures may, I think, be traced to impatience. Propagation should never be attempted from young plants, as therein lies a double

danger—the cutting itself is scarcely ever so free, and the taking away a portion of foliage from a weak plant is apt to paralyze the root and cause decay; the rooting of the cutting is therefore more uncertain and the death of the parent plant itself problematical.

Let a few plants be grown on till they get into 24-sized pots, and if they have had fair treatment cuttings may safely be taken from them without any risk of endangering their life or checking their development. Although somewhat slow of growth in the early stage, the double *Primula* will make rapid progress when once a fair head of foliage is formed, and it is not difficult to obtain specimens 2 ft. or 3 ft. through by the second season. It is when they arrive at these proportions that they become so valuable for cutting, the amount of flower produced by a large healthy plant being quite surprising. The soil which appears to suit them best is a mixture of well-decomposed leaf-mould and fibrous loam, in about equal proportions, to which may be added some thoroughly rotted manure and about one-third of silver sand to the whole. The soil should be moderately fine and moist but not wet when used, and the plants only potted with that degree of firmness which tapping upon the bench and ordinary pressure of the fingers will ensure. The crown of the plant should be kept well up and the surface of the soil made smooth and firm. During the winter and early spring months, the plants should be kept in a temperature ranging about 50° at night and 55° to 60° during the day, which will keep them gently moving, too much heat, especially at night, causing a weakly growth. Air should be given on all favourable occasions, and in spring and summer they will require shading on hot days. In damping down the syringe must be carefully used, as a few stagnant drops of moisture in the crown will cause the bloom to decay, and this will sometimes take place so suddenly as to leave no time to repair or prevent the mischief. In damp weather, too, the waterpot must be carefully used, allowing the plant to dry thoroughly before watering; a wet stagnant surface will cause decay to set in at the collar, and the healthiest plant will suddenly turn sickly and die from this cause, decay being germinated between the point where root and foliage unite. During the summer months the plants may either be kept in a cool house or turned out into a pit; provided they receive plenty of air sufficiently impregnated with moisture they will do equally well in either situation. As soon as the damp cool days of autumn approach, however, they should be replaced in their winter quarters, as a continuous low temperature will produce torpidity of the root, and if permanent healthy growth be desired, checks of this description must be avoided as much as possible. With respect to re-potting give them no greater amount of fresh soil than is absolutely necessary; let the shift be as small as possible, ascertaining that it is really required; the soil being used somewhat fine will admit of this recommendation being carried out. When once the desired size is attained, health and vigour may be preserved by an annual top-dressing and an occasional watering with guano water. The propagation of the double Chinese *Primula* may be carried on through the whole year, the early spring months being perhaps the most favourable for that purpose. They should be taken off with a slight portion of heel attached and inserted singly in thumb pots, placing them under a hand-glass upon slight bottom-heat. A little air should be left on at night, and if the glass be removed for an hour or two in the morning, it will be advantageous, preserving the foliage and preventing damping. In the summer they will root freely enough in a close house with the protection of a cloche, and when once a few large plants are obtained, the getting up of a stock of this plant is comparatively easy. JOHN CORNILL.

Byfleet.

Fuchsia Boliviana.—This *Fuchsia* is a native of Bolivia, where it was discovered by M. Roelz in 1873; it is nearly related to *F. corymbiflora*, which it somewhat resembles, although much superior to that kind in point of beauty. Its branches, which are from 18 in. to 2½ ft. long, bear flowers of the brightest coral-red; their sepals are sharply pointed and stand out boldly, being sometimes reflexed. The stamens, which are red, have white anthers that rarely project beyond the flower. This species has been a great favourite in France ever

since its introduction in 1874, in the October of which year the Central Society of Horticulture awarded it a first-class silver medal. Planted out in the open air in summer by the side of *F. corymbiflora*, it has only grown to about one-half the height of that species; and while *F. corymbiflora* does not flower until very late in autumn, *F. Boliviana* commences to bloom in the summer, and continues without interruption until checked by frost. It forms a large compact bush, frequently bearing from ten to fifteen branches, all of which terminate in a long cluster of flowers, and as the season advances it makes a second growth, so that by the end of October it is nothing uncommon to see plants of it 2½ ft. high, and only seven months old, bearing over thirty bunches of ruddy blossoms. It would, perhaps, be rash to describe this species as the most beautiful which we possess, but it certainly may be asserted that none are superior to it. Its abundant flowering qualities, the brilliancy of the colour of the flowers themselves, joined to its dwarf habit, must always place it high on the list of our best Fuchsias. It is easily grown, and thrives well in almost any soil. It may be propagated by means of cuttings, which strike root readily.

DENNING'S POT-SAUCEUR.

THE accompanying woodcut represents a garden saucer of considerable utility invented by Mr. Denning. As will be seen, it is really a circular trough, the pot standing on the inner rim. The centre, however, is not open, but a cup into which the overflow from the rim and the drainings from the pot escape and pass away through a hole in the bottom. Into this central cup the roots of some plants descend and find moisture. The advantages of this saucer are that it keeps the plants moist, without subjecting them to saturation; it

Section of Pot-sauceur.

allows of frequent waterings with fresh water without inducing rotting or stagnation of the soil. The common garden saucer, judiciously used, is a great aid to the cultivator, and answers perfectly for many purposes; but this has special value in many cases where the other would be worse than useless, and it deserves general adoption in gardens where many plants are grown. It is made for Mr. Denning by Messrs. Down & Harlock, Cheam, Surrey.

Boiler-water for Plants.—I have been in the habit of using boiler water for taking the chill off the water with which I watered all kinds of fruits and plants commonly grown under glass for many years, and I have known many others do the same without any bad effect, but I should not think of using it for syringing for fear of depositing a sediment on the foliage. For that purpose it is better to fill a few pots with pure soft water and allow them to stand on some heated surface in the houses until the water has attained the requisite temperature. Of course where hot water is drawn from the heating apparatus for watering it is absolutely necessary that the supply-cistern, even if regulated by a ball-tap, should be locked to every evening.—E. H.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Fraxinellum tricolor.—This is a free-growing, soft-wooded stove plant, introduced from the islands of the South Pacific Ocean. The leaves are olive-green, blotched irregularly with grayish purple and salmon-pink, the tints being varied more or less, according as the colours are here and there differently blended. The tendency of the marking is, however, for the older leaves to be mottled with purple, and the younger ones to assume more of a salmon tint. It is a plant which, when better known, cannot fail to be a favourite.—B. W.

Garden Frames.—These somewhat antiquated occupants of our forcing-grounds have outlived many contrivances intended to supersede them, and even where heating by hot-water has been carried to its greatest perfection, an ordinary garden frame heated by means of fermenting material still holds its own in point of usefulness, simply because its moist, warm atmosphere is more congenial to freshly-potted plants or cuttings than that of more imposing structures.—J. Groom, *Henham*.

THE FRUIT GARDEN.

THE CURL-TAIL PIPPIN APPLE.

HAVE any of your readers experience of the merits of an Apple which is much grown about Weybridge under the name of the Curl-tail Pippin?—so named from the peculiar formation of the foot-stalk, which is fleshy and curves inwards. Its principal recommendations are the general usefulness of its fruit, and the free-growing character of the which, owing to its flowering considerably later than most other kinds, generally escapes the spring frosts. As a rule, it only bears every other year, the great quantity of fruit which it produces the one year preventing the formation of bearing wood the next. Where there is a plantation of this variety, however, one-half of the trees might be disbudded, by which means an annual supply would be ensured. It is fit for either dessert or culinary purposes, and is, in fact, one of the best Apples for baking or roasting with which I am acquainted. Its flesh is delicate and juicy, and remarkably free from acidity, and it keeps well without shrivelling until May. We have been using it all through the winter, and we find it quite as good and as fresh now as earlier. It seems to possess rot-resisting powers to a remarkable degree; for, if the fruit lie in a dry place, bruises received early in the season do not appear to have the power to spread, but remain without alteration throughout the winter; the fruit is of fair size, thin-skinned, a greenish-yellow when ripe, and, where fully exposed, streaked with red on the sunny side. Some one may be able to recognise it from this description, as I suspect that it must be grown in other districts under another name—Curl-tail being, I should imagine, purely local. JOHN CORNHILL.

Fresh Figs in March.—The early Fig house in the gardens at Gunnersbury was started on November 14. Fine ripe Figs were gathered in the middle of March, and now a second crop is ripening. Mr. Richards hopes to gather Figs from the same house throughout the summer and autumn. Grapes we can buy at all seasons, but ripe Figs in March and April are not market products, though we think them as well worthy the gardener's skill as any known fruit. The Fig is a neglected fruit, at least so they think who know it well, and the fact that it may be had in perfection for so long a period should be a farther encouragement to its culture.—V.

New Belgian Grapes and Peaches in Covent Garden Black Market.—I have just seen a small box of hot-house Grapes (Black Hamburg) imported from Belgium; they are of very good quality, and are in first-rate condition, so much so, that one would almost have thought that they had been grown in the neighbourhood of London. The only fault is that the bloom is slightly rubbed. Belgian cultivators are growing these Grapes in large quantities for the London market; and they also intend sending next week hot-house Peaches, which I am informed are very good. I am afraid that some of our English growers will not like such importations as these, which are sure to very much affect our markets—Peaches coming, as they do, at least a month before ours are fit for use. We are still having large supplies of St. Michael Pines, which are of first-rate quality; and I am afraid that our Grape and Peach growers will, like our Pine growers, have to give up the culture of early fruits; as regards Pines, we seldom see an English one now in the market.—A. GARCIA, *Centre Row, Covent Garden Market, April 20.*

Span-roofed Houses v. Garden Walls.—Like Mr. Gilbert (p. 283), I would gladly exchange our garden walls for span-roofed houses—not those small narrow structures recommended years ago under the name of glass walls—but good roomy houses, which from the large quantity of air enclosed are less exposed to sudden and extreme changes of temperature. I should also like to transfer the main crops of hardy vegetables to some contiguous but less conspicuous place, where they might have something more nearly approaching open field culture than is possible under the present system. Under this plan, where in large gardens some six or eight acres are now enclosed by high brick walls, less than a fourth of that space, if enclosed by span-roof houses, would be ample, and in fruit culture this reduced space so treated would yield more certain, and consequently more satisfactory results. This enclosed garden might be devoted to fruit trees trained on the cordon system, reserving certain beds and borders for Strawberries, salads, and a few early vegetables. The main crops, as I have already suggested, could be better grown away from overhanging fruit trees, and where the spade could be fearlessly used, without running any risk of injuring the roots of trees growing near. The orchard of standard trees would of course remain as at present; and the vegetable garden, surrounded and sheltered by good Thorn hedges, might occupy a position near, and the whole might be so

arranged as to do justice to everything, which is certainly not the case under the mixed system now generally adopted. In making new gardens or remodelling old ones, I venture to recommend this idea as one deserving serious consideration.—E. HOBDAV.

The Caprification of Figs.—Your remarks on Figs (see p. 383) remind me of some very singular statements made by Tournefort, in his "Voyage du Levant." He was sent by Louis XIV. of France to report on the natural productions, &c., of Turkey, and among other things he has a great deal to say about Figs. Turkish Figs grow to a great size, as your readers may see by purchasing a box from the establishment of a West-end London grocer. Tournefort accounts for this abnormal size by saying that the cultivators, at a certain stage in the development of the fruit, bring the branches of the wild Fig and place them among the cultivated kinds. At this period a certain moth emerges from the pupa form, and soon after begins to lay its eggs. It deposits these at the eye of the cultivated Fig; and Tournefort asserts that the process, which is known as caprification, causes an irritation in the fruit, and leads to a greater flow of the secretions of the plant to it, so that it develops to an unusual size. He states that this plan may be tried at home by puncturing the growing fruit at the eye with a silver pin or bodkin dipped in sweet oil. This would be worth trying. I have not the book by me, and quote from memory; but if Tournefort be right, the presence of so many grubs in our Fig boxes would be accounted for. Many kinds of Figs are imported into England, the so-called wild or "natural" Figs among them.—P.

The Spur System of Pruning Vines.—The statement (see p. 383) of Mr. Douglas—a grape grower of ability and experience—that the spur system of pruning Vines produces barrenness and debility if continued for years, I read simply with astonishment. A more misleading statement was never penned. I am myself an advocate for moderate and constant extension, but I would not venture to limit the time at which Vines would cease bearing altogether, and only be "able to produce weakly growths which never showed fruit, nor never would," because they were spur-trained, if cultivated with ordinary skill. I could show Mr. Douglas examples of Vines here and elsewhere which have been restricted to single rods and spurred in close for nearly twenty years, without abating perceptibly either in vigour or fruitfulness. I speak within safe limits, for I found Vines here (and had good crops off them for some years) that appeared to have been spur-trained from time immemorial, and I have no doubt that plenty of similar instances could be furnished. When I saw the great Vine at Hampton Court years ago, it looked to me as if it had not extended its bearing limbs for a century, for they were as thick as my arm, and spur-pruned, if I recollect aright.—J. S. W.

Pears on Apple Stocks.—These are of no value; they will only live for a few years, and even during that time they are spindly, and the fruit is small and worthless; such, at least, is my experience, and the same also applies to Apples grafted upon Pears. Some years ago I put 100 Apple grafts, consisting of twenty sorts, on healthy young Pear stocks, and all, or nearly all, grow pretty well. Some did very well the first year, the second year more than half failed, and the third year only six were alive, and these consisted of Golden Winter Pearmain. They bore fruit about as large as a small hen's egg, sour and worthless, and then they died.—J. Scott, Merriott, Crewkerne.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

St. Michael Pine-apples.—Last week I tasted one of these Pines, a Smooth Cayenne, weighing 7 lb. It cut up particularly firm, without the blemish of a black heart, and was very rich and excellent—in short, it was a better Pine than could be grown at this season in "Merriott England."—E. GILBERT, Burghley.

Green-fruited Black Currant.—I have grown this Currant for the last twenty-five years, and have known it nearly double that time. It cannot be so scarce as your correspondents imagine, as I have from time to time sold large quantities of it. It has one good property, the birds do not meddle with it until all other sorts are over. I have described it in p. 170 of "The Orchardist."—J. Scott, Merriott, Crewkerne.

Evils of Grafting on Large Branches.—Established trees cut back and re-grafted are almost sure to be fruitful, i.e., if moderate-sized branches be grafted, as the wounds in that case heal quickly, and the check given to the tree induces fruitfulness, but if large limbs be operated upon, it is impossible for the wounds to heal, and dead wood is the result, which, being exposed to the weather, quickly rots, and the accumulating moisture causes the whole tree to speedily decay.—J. GROOM, Henham.

The Weather and the Fruit Crops.—On the morning of the 15th inst. the thermometer registered here 6° of frost, and Gooseberries and Currants being about flowering have sustained some injury. I see that the bunches of the Currants only now show a few blossoms likely to produce fruit at the points, all the earliest opened flowers being destroyed. All the young Gooseberries are likewise injured at the top of the bushes, but the foliage saved those lower down. Pears, Plums, and Cherries had not opened their flowers at the time, and they are as yet apparently safe.—W. TILBURY, Felbeck.

THE FLOWER GARDEN.

HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

THE pale green yellow *Uvularia* of last week is now a rich gold colour, and the round buds of the Bloodroot (*Sanguinaria*) have changed to very handsome star-shaped blossoms 2 in. across. The gardens are now full of the early flower-garden Tulip, mentioned a few weeks ago as then opening its earliest blossoms. These Tulips seem to have withstood the severity of the season better than the Hyacinths, or, indeed, any other flower. One of the brightest gems in the garden flora of the week is the deep rosy American Cowslip (*Dodecatheon splendendum*), of which there is a number of plants in the Wellington Nurseries. It is a lovely rock garden flower, and thrives on the level ground in good soil. It appears somewhat earlier than the common American Cowslip. The Evergreen Alkanet (*Anchusa sempervirens*) is full of flower; it is a plant for groves or shrubberies, in a semi-wild state. The ground Ivy and the blue *Nepeta* are opening their flowers, as is the Myrrh (*Myrrhis odorata*) an inhabitant of the old herb or medicinal garden, which deserves a place in collections for its grace, its odour, and its flowers. It would do well on any rough bank, or in any copse. The Globe-flowers are out on the London clay, not yet of their true colour, and various herbaceous Euphorbias are opening their greenish-yellow

White Mountain Narcissus (*N. montanus*).

flowers, not without beauty and effect; they are mostly fitted for shrubberies or rough banks. The quaint-looking Pennsylvania Saxifrage, the Ivy Saxifrage (*Saxifraga Cymbalaria*), and Veitch's Primrose (*P. cortusoides amona*) are beginning to flower in the open ground. The Solomon's Seal is opening its earliest flowers on the warm soils round London; it is one of the many hardy flowers that might adorn the surfaces of our shrubberies if the practice of annual digging were abandoned, as it probably will be some day. A tuft of the rich purple Crocus-like *Triteleia Murrayana* is flowering in Messrs. Barr & Sugden's bulb grounds at Tooting, its foliage being linear and similar in general appearance to that of the large-flowered *Sisyrinchium*. The soft yellow-flowered Dog's-tooth Violet (*Erythronium grandiflorum*) is also now in bloom, and is a most desirable plant; it bears two or three reflexed Lily-like flowers on a stem a foot in height, the green undulate-margined leaves being marbled with pearly grey. Some forms of the Apennine Windflower (*Anemone apennina*) are now in blossom, one of the rarest being *A. alba*, while the prolific *A. bracteata* is remarkable for its singularity when closely examined. Of all the forms of the wood Anemone now in flower a broad-petaled bluish-lilac kind, on the rock-work at Kew, is the best; its blossoms are as large as a florin, and they rise from amongst fresh green foliage like that of the type. This plant is even more beautiful, although not so early, as either *A. blanda* or *A. apennina*; it is known in gardens as *A. Robinsoniana*, and at Kew as *A. nemorosa purpurea*. Several *Fritillarias* of the *F. Meleagris* section are now very effective; one called *F. rosea*, the colour of which is white with rosy tessellations, is very effective, and *F. alba*, a white-flowered variety, is also just now

American Cowslip (*Dodonaea Meadia*).

Plumy Delytra (*Delytra oximia*).

Evergreen Alkanet (*Anchusa sempervirens*).

Pennsylvanian Saxifrage (*Saxifraga pennsylvanica*).

Ivy Saxifrage (*Saxifraga cymbalaria*).

Solomon's Seal (*Convallaria Polygonatum*).

Narrow-leaved Bitter Vetch (*Orobus flaccidus*).

Cyclamen-flowered Narcissus (*N. triandrus*).

Globe-flower (*Trollius europaeus*).

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

very beautiful, bearing egg-shaped flowers on tall gracefully-arched stems, like those of the common Solomon's Seal. The vivid orange scarlet-flowered Tulipa Griegi is likewise now much more effective than when we saw it a fortnight ago; it is a kind which is readily recognised by its glaucous leaves being heavily lined and blotched with dull purple markings, and one which henceforth is destined to occupy a place along with its allies, *T. gesneriana* and *T. sylvestris*, the latter of which is also in bloom, its graceful habit making ample amends for its want of brilliancy in point of colour. Several late-blooming species of Narcissi are now in great beauty, and among these one of the most graceful is the reflexed or Cyclamen-flowered Narcissus (*N. triandrus*), which has bright green Rush-like leaves, and pale lemon-petaled, white-capped flowers, numbering four or five on a scape. In Mr. Parker's nursery it is just now in perfection, along with the pigmy *N. juncifolius*, and several distinct forms of the Hooped Petticoat Daffodil (*N. bulbocodium*). The drooping White Mountain Narcissus (*N. montanus*), or *N. galanthifolius*, as it is sometimes called, is now in bloom at Kew, and well deserves a place in all select collections. In the same establishment are also six distinct forms of the common *Caltha palustris*, to which we alluded a week or two ago, and very beautiful they are, growing as they do by the margin of a shallow stream. The best of the single-flowered group has blooms as large as a crown piece, and of the purest golden-yellow colour. This variety is an effective plant for the margins of ponds, ditches, and brooks, as is also the rich orange form with double flowers, known as *C. palustris minor fl.-pl.* One of the sweetest and prettiest of all hardy aquatic flowers now in bloom is the Hawthorn-scented *Aponogeton distachyon* and its varieties minor and acuminata, all of which, however, have been in bloom since last Christmas. The Water Violet (*Hottonia palustris*) is likewise now opening its pale pink blossoms, and the surface of nearly every sunny pool is enamelled with the silvery star-like flowers and fringed leaves of the Water Ranunculus (*R. aquatilis*). Iris nicaualis is showing colour in the open border, and associated with it are its allies, *I. pumila alba* and *I. pumila cœrulea*, the one white, the other delicate sky-blue. Among the various species of dwarf Vernal Phlox, a deep violet-carmine form of *P. setacea* is now especially beautiful, forming dense tufted masses of starry flowers; the glaucous-leaved *Opmalodes Luciliae*, too, is also very lovely, its flowers being nearly as large as a shilling, and of the most delicate porcelain blue tint imaginable. One of the earliest and most distinct of all the Larkspurs is *Delphinium nudicaule*, a kind which is now opening its dull scarlet flowers.

Anemones at Drayton-Beauchamp.—Few flowers in my garden please me more at the present time than the little vernal Anemones. *A. Pulsatilla* was very bright and gay till Good Friday, but the thick covering of snow under which it was buried for nearly two days has washed out all its colour and made it a perfect wreck. *A. ranunculoides* has stood the battle of the elements bravely, and its golden flowers are almost as fresh and bright as before the storm. *A. apennina* had the wisdom to keep most of its cerulean buds unexpanded till the worst was over, and to-day (April 18) it is looking very beautiful. Its white variety is a gem in its way, well-matched by the pale straw-coloured form of *A. ranunculoides*, which I had from Kew under the name of *A. ranunculoides nemorosa*. *A. bracteata flore-pleno* is a grand plant; I know nothing prettier than a fully-expanded patch of its pearly stars, each with its green and white frill. *A. nemorosa major* is a very specious plant when left alone for several years and allowed to become a strong clump; and *A. trifoliata*, with its very distinct three-lobed leaves and white flowers, is very delicate and graceful. The Queen of them all, however, is *A. nemorosa cœrulea*, otherwise *A. Robinsoniana*, which has the outside of the petals white, and the inside the most lovely pale sky blue. I have nursed up my tubers till I have enough to plant round a standard Rose tree, and a fair and lovely sight it is to behold. *A. stellata*, *pavonina*, *hortensis*, *fulgens*, and *nemorosa flore-pleno* are all beginning to open out, but have been much nipped and checked by the inclement weather. *A. narcissiflora*, *sulphurea*, *vernalis*, and *sylvestris* are pushing up, and so is a small pale yellow species with a much divided leaf, which I had as *A. dichotoma*. *A. palmata* with me just lives, but never flowers, and I have never yet succeeded with *A. alpina*. Seedlings of *A. baldensis* are growing well, and I hope

next spring to add this to my list of flowering plants. I hope it will not be long before some one introduces the white variety of *Anemone Pulsatilla*, and the pink and white forms of *A. blanda*.—H. HARPUR CAREWE, Drayton-Beauchamp Rectory, Tring.

The Official Rhubarb as a Decorative Plant.—It is mentioned (see p. 376) that the Official Rhubarb (*R. officinale*) would seem, by the vigorous way in which it is coming up at Kew, to be of some value as a decorative plant. In my opinion an established plant of this fine Rheum is (with, perhaps, the exception of *Ganera manicata* or *G. scabra*.) the most imposing of all fine-leaved herbaceous plants. There is a fine specimen of it at Kew. It is perfectly hardy, though the huge leaves begin to unfold themselves so early that they are often injured by spring frosts. A plant here, though little more than one year old, is already effective, much more so than the better known Rheum Emodi.—OXON.

A Bank of Rose Trees.—The simplest and most effective way of producing a good display of Roses is to plant three or four rows on each side of a walk—standards, half-standards, and dwarfs, each row a foot lower or higher than the next—say, the front row all dwarfs, the second worked on stocks 1 ft. high, the third 2 ft., and the fourth 3 ft.—the heads of the lowest hiding the stems of those above them. The plants should be set about 2½ ft. apart. When the whole are in flower, one has a bank of Roses on each side of the path, the effect of which is showy in the extreme. None but free-blooming hybrid perpetuals should be used for this purpose, and they should be allowed to grow freely without using the knife. They must be well manured, and watered with liquid manure during the growing season.—HENRY TAYLOR.

Plant Collecting in the Tyrol.—"Wanderer," in his "Botanical Tour through the Tyrol" (see p. 391), mentions *Campanula pulla* as one of the plants met with on the Schlern, near Botzen, but in this, according to the following extract, I feel inclined to believe he must have been mistaken. Baron von Hausmann writes about this plant in his "Flora von Tyrol," p. 554, 1851:—"C. pulla has become doubtful for the Tyrol; the positions indicated by Pollini belong, according to Bertolini, to C. Morettiana. Perhaps it may occur in the mountains bordering on Salzburg and Styria. In Switzerland, likewise, according to Mortzi, it does not occur; nor could it be found on the Glockner by the chaplain, David Pacher." The fact of the author of the "Flora von Tyrol" being himself a resident of Botzen, in the close vicinity of the Schlern, makes it appear most unlikely that he should have overlooked the plant if it really did occur there.—SCHOLASTIKA.

Root-grafting Seedling Briers.—Some twenty years ago, Roses being greatly in demand at Lyons, especially dwarf kinds, M. Guillot conceived the idea that quick results might be obtained by budding on young seedlings of the Dog Rose such kinds as did not grow readily from cuttings. The seed of the latter was sown in February or March under glass, and the young plants were pricked out when about a year old. In August or September they were fit for budding, when the soil was stripped from the bases of the shoots, and the buds were inserted as closely as possible to the collar. After they had taken, the stems of the Dog Roses were cut off, and the shoots from the buds allowed to take their places. The tops of the Dog Roses being thus destroyed, their roots do not produce a single sucker, and the shoots from the buds become completely identified with the roots on which they have been worked. Roses propagated in this way are said to acquire increased hardiness and vigour, the Dog Rose stocks furnishing them with large quantities of roots. So much we learn from the "Cultivateur" of Lyons.

Pentstemon Crimson-Bedder.—As its name suggests, this claims to be useful for bedding purposes, and so it indeed is. It is a compact and vigorous sort, yet comparatively a dwarf grower—reaching the height of 18 or 20 in. at the most. It is a most abundant bloomer; the flowers are a very rich crimson, with a dash of purple in them, and with white throats slightly suffused with purple. For back lines in wide borders, or in centres of large beds, it presents a shade of colour not common.—"The Gardener."

Single Wallflowers.—These make excellent centres for large beds or back lines for ribbon borders, or, perhaps, better than either, for furnishing balcony and window-boxes. When associated with dwarf hardy edging plants and early flowering bulbs they have a good effect, even during the dullest months, and in spring their delicious fragrance is especially welcome, many of our other popular early flowers being scentless. I find the dwarf Blood Red and Belvoir Castle Yellow the most serviceable kinds, and by sowing seeds of them early in April and pricking out the young plants in single lines as soon as they are large enough to handle they form neat little bushes furnished with abundance of foliage to the ground.

When lifted in autumn great care should be taken to keep their roots intact, and they should be replanted firmly and somewhat deeper than when they were in nursery beds. Should they get away by the wind, which they sometimes do, they should be firmly secured by pressing the soil closely round the bases of their stems. In mild winters well-matured plants commence to flower very early, and as the season advances great care should be taken that plenty of moisture is supplied, or they will quickly run to seed.—J. GROOM, *Hensham*.

Destruction of Primrose Flowers.—I have often had Primrose blooms injured in a similar way to that complained of by "Essex" (see p. 380), and I have always attributed the mischief to some small birds destroying the calyx to get at the nectar situated at its base. I have, however, had much greater damage done by small birds to the large compact double flowers of the French and African Marigolds in the autumn, and have seen the soil beneath a bed of these plants literally strewn with their petals. I have hitherto been unable to ascertain what object the birds had in view in this case, not having as yet found insects in the flowers sufficient to warrant such wholesale destruction.—A. D.

Wild Gardens and Woodland Flowers.—You will, I feel sure, be liberal enough to let me make a respectful but emphatic protest against such wholesale spoliation of our woodlands as that practised by "Forester" (see p. 352), whose three cartloads of Daffodils appear to inspire you with satisfaction. Why, he must have stolen myriads and myriads of these lovely bulbs from a spot where they were a joy to many, in order to transplant them to a private drive, where at best only a few can appreciate them. Try to realise what three cartloads mean, and you will not think my protest unreasonable. You can put ten or twelve clumps, containing each as many bulbs, soil and all, in a hand-basket. Three cartloads would cover as many decent-sized copses. I know well what digging up Daffodils means. I have often done it, but I hope I have made it a point of conscience to select and spare. I love my wild garden, and have brought plants to it from many a county—aye, and many a country outside Great Britain; but I should hold it a sin against the happiness of others, and against the prodigal bounty of Nature—who does not construct private drives—to dig up without compunction. It is always enough to take one's specimen conscientiously, and let it grow and multiply. In places where species are scarce, it is well to mark the spot, and wait till the plant has developed and spread. I trust you will see that there is something selfish in wholesale cartloading away of the flowers of our meadows, banks, hedges, and copses, and that if encouraged it will certainly endanger not the wild gardens but the woodlands.—EX-MOUTH. [Our correspondent should remember that others may transplant judiciously as well as he. In the case referred to, hardy plants were simply brought from a wood which they overran to the margins of green drives, where they may increase and beautify the ground. There are many woods from which waggon-loads of the Lily-of-the-Valley might be removed without the plant being in the least danger of extirpation. We may find a populous colony of Solomon's Seal in a quiet rarely seen nook, and do good by dotting it here and there in woods where it does not occur. There is a marked difference between the increase of beautiful plants by transplanting them, and the destruction of rare species by gathering them, often root and branch, to exhibit at flower shows.]

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Seedling Alpine Auriculas.—I can fully confirm the truth of Mr. Taylor's remark respecting these (see p. 340) and would strongly advise all lovers of Auriculas to lose no time in carrying out his recommendations regarding them for, even if they already have a choice collection of named varieties, they will derive both profit and pleasure from raising every year a batch of seedlings. I have many fine kinds in flower now, which shows that seedling raising well repays the small amount of labour attending it.—J. GROOM, *Hensham*.

To Destroy Ants in Flower Beds.—A very effective plan is to pour a little quicklime on the mouth of their nest, and wash it in with boiling water. Should they have formed their nest at the root of a plant, pour upon them a quart or so of warm water, in which a moderate-sized piece of camphor has been steeped. This (says the "English Mechanic") effectually destroys them, and is not in the least injurious to the plants.

Orubus cyanus.—I am glad that Mr. Niven (see p. 333) gives a well-deserved tribute of praise to this pretty little *Orubus*, which is now in full beauty and should be seen in every garden.—OXF.

The Japan Rose from Root-cuttings.—We learn from Mr. Perry that even the finest fibres of the roots of the handsome White Japan Rose (*R. rugosa* also) afford strong plants soon after their insertion.

A Pretty Spring Contrast.—The Grape Hyacinth and common Primrose make a beautiful mixture when the former is grown thickly and in well-established clumps.—P.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Fuchsias struck last summer and that were placed in their blooming-pots some time ago will now be coming into flower, and should be encouraged with manure-water as soon as the pots get moderately filled with roots; this will tend to prolong their flowering, but, in applying liquid stimulants to Fuchsias, care must be taken that the dose be not too strong or it will cause the unexpanded flowers to drop off; the Fuchsia will not bear so powerful a stimulant as the majority of free-growing plants. Fuchsias are also very subject to red spider, which can only be kept down by a constant use of the syringe. Amateurs will find it a safe practice to syringe the plants even after they come into flower, as their bloom will in no way be injured by the water if applied gently, and let them especially notice that it gets to the under side of the leaves so that the whole surface may be moistened, or it will not be effectual. Inattention to this matter is frequently the cause of these most useful and generally-grown plants becoming shabby and partially denuded of leaves long before they otherwise would be if in vigorous health. Old plants that have been cut back, shaken out, and re-potted, will come early into bloom; but in cases where it is more desirable to keep a portion for flowering later in the summer, they should be moved into larger pots, have their shoots repeatedly stopped, and not be exposed to too strong a light. Plants treated thus will be much larger and the flowers proportionately more profuse. A position under the partial shade of Vines will be suitable for these, as the effect of too bright a light on Fuchsias when the days are long is to stop further growth and induce a determinate disposition to flower.

Pelargoniums of the show and fancy kinds, that are intended for early blooming, will now be benefited by the application of manure-water once a week; this will not only increase the size and appearance of the individual flowers, but will enable the plants to produce a succession of bloom much longer than they would if nothing of an invigorating nature were added to the manurial elements contained in the soil in which they are grown. The great advantage in the use of liquid stimulants to the majority of plants whose roots are confined within the limits of a pot, is that it sustains and prolongs a vigorous development just at the time it is required; whereas if the soil be made too rich in the first instance at potting time, the result is the production of rank growth early in the season before the formation of flowers takes place, which is generally detrimental to free blooming. Zonal Pelargoniums, to succeed the foregoing, should receive the necessary attention in trying out, stopping the shoots to induce a bushy habit, and the removal of all flowers when they first appear that will expand before the desired time; for although these plants are very free and continuous in their disposition to bloom, yet they produce a much greater head of flowers, and are more effective when not allowed to open for an indefinite period. Though useful decorative subjects, it is not advisable to grow too many of these Zonal Pelargoniums; their easy culture and the undue prominence of late given to them has induced many amateurs to plant them in such numbers as to exclude that variety so essential in plant houses, and to make the contents in some cases little better than mere collections of these plants.

Hydrangeas, now showing flower, will also be much benefited by manure-water; if in small or moderate-sized pots (in which they are much the most useful) they will succeed better if the flowering shoots be thinned out, as this operation will cause the blooms to come much larger. Most useful summer decorative subjects, commandable alike for their easy growth, and handsome flowers produced for a considerable period, are the blue and white varieties of *Campanula pyramidalis*; if a number of these plants be grown they will come in bloom about July, when indoor flowers are scarce; they are equally adapted for mixing with others in the greenhouse, conservatory, or for room decoration; for the latter purpose there are few summer-flowering plants so well suited as these, their natural habit being such that they do not become drawn, thus spoiling their appearance by the partial light they must necessarily receive in such places. They should have pots proportionate to their strength and size. A plant in the size to which it is intended to grow them. A plant in a 10-in. or 12-in. pot will produce spikes 6 ft. or 8 ft. in height, if well managed; they can be planted in such places that are about to suckers produced from the base of the former, the suckers should flower, or from seed; in the case of the former, the suckers should be now taken off; they will in most cases have formed a little root, and should be placed singly in small pots, and covered with a bell-glass for a few weeks until they get established, after which they must be gradually inured to the air. They are easily managed, and succeed well in ordinary loam mixed with some sand and decomposed manure; move them into 6-in. pots in the summer when well rooted, and subject them to ordinary greenhouse treatment, with sufficient

light, air, and water. If required to be grown from seed, sow at once in a seed-pan, drained and filled with sandy loam, to which has been added one-fourth of leaf-mould. It is necessary that the soil in which all similar seeds to these are to be sown should be light, otherwise the roots of the young plants get much injured when they have to be transferred to single pots. Make the surface quite smooth and sow the seeds thinly, covering them with about an eighth of an inch of fine soil; they will germinate in a greenhouse temperature, but more quickly if the heat be somewhat increased.

Pits and Frames.—*Primulas* and *Cinerarias* should now be sown in pans, drained, and filled with light sandy soil; sprinkle some sand over the surface, which press even with the bottom of an empty flower-pot, then gently water it so as to close up the interstices into which the seed would otherwise be liable to get washed too deeply by subsequent waterings. The *Cineraria* seed may be slightly covered with a little sand, again pressing the surface smooth; until they have germinated do not give more water than will just keep the soil in a somewhat moist condition. The *Primula* seeds should be slightly pressed into the surface so as to be partially embedded, but they succeed better without being covered further than by placing a sheet of glass over the top of the pot to prevent the surface from drying, thereby avoiding the application of water, of which the less needed the better until the plants are up. Place the pots at the bottom of the frame or pit so that the sun will not absorb the moisture from the soil. A temperature of 50° or 60° during the night will be sufficient. If the plants be well attended to throughout the summer, never allowing them to get checked for want of water or pot room, they will flower as early as required. Tomatoes that were sown recently will now be ready for potting off; place them singly in small pots, water and shade them until the roots have got hold of the soil, after which they cannot have too much light to keep them in dwarf and vigorous growth. Melons sown to occupy the frames which will shortly be cleared from bedding plants, should, as soon as they require it, be moved into larger pots, in order that they may not get stunted before the frames are ready for them. Hot manure should at once be got together in sufficient quantity, and thoroughly prepared for making up the beds by frequent stirrings.

Bedding Plants.—Continue gradually the hardening process, so as to have them in a proper condition at planting-out time: in the interval the beds should be made ready. Where spring bedding is made a feature in the garden, it is frequently perplexing which to sacrifice—the springer the summer bedding plants—especially at such a season as the present, when the spring plants are at their best; but it must be borne in mind that if the summer bloomers are not put out in the beds at the proper time they have little chance of making a prolonged display, and, when not planted until late, the autumn frosts are upon them soon after they have become effective. The beds that are to be filled with the more tender sub-tropical plants that should not be planted out before the beginning of June, or such as are to be filled in carpet style, where *Colons* and *Alternantheras* hold a conspicuous place, can of course remain with their spring-flowering plants undisturbed. In moving all that are more immediately in the way, the place in the reserve ground that they are to occupy should first be prepared by digging it well, and if the soil be poor add some manure to it; by this means there will be no delay in transferring the plants from one place to the other. Give all a good watering as they are placed in their summer quarters, and those that are larger than required, or are found necessary to increase, should be divided. In preparing the beds for the summer plants, it is necessary to treat them according to the requirements of the various subjects to be introduced. Such as *Ageratum*, *Verbenas*, and *Calceolarias*, or others of a similar quick-growing nature, need a much richer soil than *Pelargoniums*, which latter, if put in ground that is over-rich, will run too much to leaf. Quick-growing plants like the former require a quantity of food, and if the soil be not rich enough they are slow in covering the ground, and are not able to continue growing and flowering to the end of the season; but with these, as with all other plants that need considerable sustenance, it is much better occasionally to introduce some new soil than to rely upon manure alone. This recommendation specially applies to *Calceolarias*; one of the chief causes of failure in these is their being placed in beds that have year after year been occupied by them or other plants of a similar nature, the soil becoming exhausted of the elements necessary to sustain them, and which are not supplied by manure alone. Remove 6 in. of the effete soil, and re-place it with that of an ordinary pasture, and great benefit will result to the plants. Where manure is required, particularly if the soil be of a dry light nature, well-decomposed cow manure is much preferable to horse manure, as the former is more cool and moist, and will keep the plants through a dry season in better growth.

PLATE XVIII.

CLEMATIS VESTA.

Drawn by H. HYDE.

IN giving a coloured figure of Messrs. Jackman's *Clematis Vesta*, one of the most beautiful, if not the most showy, of the newer kinds, we take the opportunity of alluding to some of the more valuable of the recent novelties, including *Vesta*, raised by that firm, which has been so successful with these superb hardy flowers. Foremost amongst the kinds belonging to the *C. patens* type, which consists of climbing large-flowered spring-blooming *Clematises* that flower from the old or ripened wood, we find *Fair Rosamond*, a blush-white kind, with a somewhat indistinct wine-red bar up the centre of each sepal, the stamens being very prominent and distinct. This flowers in May and June. Then comes *John Murray*, a remarkably free-growing and free-blooming variety. Its flowers, which are eight-sepaled, are of a deep purplish-mauve, becoming reddish towards the base of the bar. This is a very showy kind, somewhat intermediate in season between the spring and summer varieties. *Lord Derby* is another free-growing and abundant flowering variety of the *C. patens* type. Its buds are large, erect, and woolly, a good deal resembling those of *C. lanuginosa*, while the flowers, which are eight-sepaled, are of a pale lavender or bluish-mauve colour; the sepals very much overlap, so that the flower is remarkable for its fullness. The anthers are reddish-purple, and the filaments white. *Lord Mayo* also belongs to the *C. patens* group, and, like the rest of that type, is furnished with ternate leaves. Its flowers, which are about 5 in. across, consist of eight elliptic-oblong sepals, of a deep rose-lilac colour, becoming darker towards the base in the central bar, which is well marked; the stamens have white filaments and long deep chocolate-purple anthers. The flowers are sweet-scented. *Sir Garnet Wolsley* is another striking variety of the *C. patens* or early spring-flowering group. The leaves are of the usual ternate character, with ovate leaflets. The flowers, which are very distinct and attractive, are nearly or quite 6 in. across, of a slaty-blue ground colour, having in the young state a very effective dash of bronze, and in the matured condition a showy and distinct bar of plum red, relieved by the tuft of white stamens tipped by dark purple anthers. *Stella* has flowers of a light violet or deep mauve, with a distinct bar in the centre of each sepal of a deep reddish plum colour; the flowers are delicately scented. The *Queen* has flowers of a delicate lavender or mauve-like tint, having much the appearance of moderate-sized blossoms of *C. lanuginosa*. *C. Vesta*, as will be seen, a marked acquisition as an early-blooming white variety. Its leaves are ternate with elongate ovate acute leaflets. Its flowers, which are of large size, are remarkable for their fullness of outline, measuring 5 in. across, and consisting of eight or more spreading sepals. It has conspicuous tufts of purplish stamens, with white filaments, which set off the flowers to great advantage, and it has a well-marked but delicate Primrose-like fragrance. It has been awarded a first-class certificate both by the Royal Horticultural and Royal Botanic Societies. In the *C. florida* group, which consists of climbing summer-blooming kinds that flower from the old or ripened wood, the newest and most striking variety is *Countess of Lovelace*, a vigorous-growing sort, superior even to *John Gould Veitch*, both in habit, colour, and form. Its leaves are ternate, with broadly ovate leaflets; its flowers have sepals of a bluish-lilac, forming a guard to the flowers like the guard-petals of a *Hollyhock*, within which is a rosette of smaller sepal-like bodies, which are of a deep bluish-lilac to the base, forming a full double flower; in the centre is a tuft of white filaments and yellow anthers. It has the peculiarity of the flower-stalks being pendent, while the blossoms themselves turn upwards, and are thus shown off to the best advantage. It is one of the best of its class. In the *C. lanuginosa* type, which consists of climbing large-flowered summer and autumn blooming kinds, that flower successively on short lateral summer shoots, the following are the best, viz.:—*Mrs. Moore*, a variety belonging to the intermediate group; its leaves are deeply cut, with rather large ovate leaflets; its flowers are remarkable among the mid-season varieties for their size, measuring as much as from

8 in. to 9 in. across; the sepals, six in number, are white, showing in the young state a slight mauve shade along the bar. The other is *Beauty of Surrey*, a handsome hybrid. Its flowers are of a light greyish-blue colour, which render it an admirable plant for contrasting with those having flowers of a dark hue. It has been described as a great advance towards a bright blue summer Clematis. In the *C. Jackmanni* type, which consists of climbing, mostly large-flowered, summer and autumn blooming kinds, flowering successively in profuse continuous masses on summer shoots, *Lady Stratford* or *Redcliffe* is an improvement on some of the older varieties. Its flowers, which are eight-spalled, measure fully 6 in. across, and are of a delicate mauve colour with a greenish tint in the centre bar or rib; the anthers, which are at first chocolate-red, soon become grey. Of this, and others of the *Jackmanni* group, striking buds may be made in the flower garden.

As regards culture, where it can be provided, a rich soil of a light loamy texture is the best for Clematises, and if this be mixed with chalk or lime, so much the better. Thorough drainage is indispensable to good healthy development; and the vigour of the plants must be kept up by at least annual manurings with horse or cow manure. On dry hot soils, cow manure would probably be preferable, while on heavy soils a thorough dressing of good leaf-mould would be beneficial. Mulching in winter also increases the strength of the plants and the size of the flowers. Pruning is an important point. That of the varieties belonging to the *Montana*, *Patens*, *Florida*, and *Lauginosas* types should take place in February or March, and should consist in removing all weak straggling or overcrowded branches. In some of these types the plants flower from the old or ripened wood; therefore, to secure blossoms, the strong one-year-old wood should be trained in, as far as it has become thoroughly ripened, beyond which it may be cut away, the retained parts being so disposed as to fill up all vacant spaces. The varieties of the *Viticella* and *Jackmanni* types are mostly large-flowered summer and autumn blooming plants that flower on the young or summer shoots, which later should be cut back each season, as soon as the frosts have disfigured the plants, say in November, to within about 6 in. or so of the soil.

Bare Shrubbery Borders.—There are now acres of bare, ugly, dug borders in the parks of London. This practice of digging old shrubberies is as injurious to the trees in London as the smoky atmosphere, for most of the roots in the best part of the soil are thus annually destroyed. It is even more destructive to herbaceous plants, many of which thrive well in London in ordinary soil if let alone. All these acres of bare surface might at this season be alive with beautiful hardy flowers, and the trees and shrubs be all the better for the ground not being dug for years at a time. Dressings might, of course, be added where needful, and weeds would have to be kept down. We know that the practice of digging annually is an old and well-established one, but trust the various superintendents of our public parks will not, for that reason, let the evil continue. In the parks about London, the shrubs are frequently trimmed like fighting cocks previous to the digging being done, and this annual clipping of the tops as well as roots produces a miserable result in the end, as anyone may see in many parts of the parks. It is surely a pity that the labour thus wasted is not directed to the proper culture and development of each species as far as position and circumstances permit. Why should we not have specimen Lilacs instead of scare-crow Lilacs in our parks? and so of other trees. Where they are let alone on the turf, the result is often as good as could be desired. Our public parks are now becoming important gardens, and we appeal to the various able superintendents to give this subject the attention which it deserves. A shrubbery is as well worthy of proper culture as anything else, and all garden plantations should be made to express the highest beauty of which the plants are capable, considered as to their general effect or as to the beauty of individual kinds. It is right to add that while there is as yet too much of the evil we point out in Battersea as well as in other parks, there are in it signs of improvement in this respect. By several of the walks we may see good specimens of shrubs mutilated neither above nor below the ground, and there is evidence of a desire to regard hardy shrubs as living things planted for their beauty, and to treat them accordingly.

GARDENING FOR THE WEEK.

Stoves.

Now that the sun has so much power fires should be kept in abeyance so as to have as little artificial heat as possible during the day. Keep the pathways and other available places well damped, that the atmosphere may at all times be sufficiently charged with moisture to maintain the plants in a healthy vigorous condition. The ventilators should be closed early to shut in the sun-heat and so raise the temperature 15° or 20°, which, if accompanied with a good syringing, will be of material assistance in promoting free growth and holding insects in subjection. Where climbers are grown and trained to the roof, frequent attention will now be requisite in thinning and regulating them that they may not obstruct the light and air from the plants beneath them.

Bougainvilleas.—That most useful of all stove climbers, *Bougainvillea speciosa*, will now be everywhere gay with its lovely mauve-coloured bracts, to which, in their young state, green fly is particularly partial. The excreta these exude soon disfigure the flowers so much as to render them of little value, and therefore, to make sure of having them clean and perfect in form, the house should be fumigated whenever they make their appearance. Avoid syringing or wetting the coloured leaves, as, when that is done, they soon fade and lose much of their beauty. Rub out any strong gross shoots as soon as they show themselves, leaving only such as are of medium size to replace those now blooming. *B. glabra* is of equal value, and comes in well to succeed the above. Keep the shoots of this freely thinned-out to admit plenty of sun and air among those remaining, otherwise they do not flower in a satisfactory manner. Any that are growing in pots for exhibition or general decorative purposes should be stationed well up to the light and fully exposed to the sun, keeping the shoots thinned, tied, and regulated as growth proceeds. The propagation of autumn and winter-flowering plants ought not to be longer delayed, or the season will be too far advanced to afford time for growing them to a serviceable size.

Poinsettias are first in importance for the above purpose, and cuttings of these should now be made either from the ripe wood or the young growth taken off with a heel. If by the former method, pieces about 3 in. long, that are hard and short-jointed, suit best for the purpose. These should be inserted in sharp sandy soil sufficiently deep for only the top bud to remain visible, and then placed in a brisk bottom-heat, where they will soon start into growth. Single eyes with half-an-inch or so of wood attached to each end strike just as readily, and make strong plants with single stems that are sure to carry fine heads of their splendidly-coloured leaves. For general purposes, these are perhaps the most desirable; but where larger sizes are required, a portion of the old plants must be cut back to within a few inches of the pot, and then started to grow. As soon as the shoots are half-an-inch long, shake out the plants from the old soil, and re-pot in good fibry loam, after which place them in bottom-heat for a few days to give them a start. If kept far from the light they soon become drawn, and therefore directly the roots are on the move the plants should be placed on shelves close up to the glass, where they will obtain plenty of air and a temperature ranging between 60° and 70°, in which they will make good stocky plants. Poinsettias are rather subject to red spider, especially if they are allowed to get dry at the roots, or are grown in a house that has not a sufficient amount of moisture in the atmosphere. To preserve them in health and free from such pests, syringe freely among the leaves and pots every morning and evening whenever the weather is bright and clear. *P. pulcherrima* has now a formidable rival in the new variety named *plennisima*, to be sent out by Messrs. Veitch in May, and to which the old favourite will shortly have to give place. This has all the good qualities of *P. pulcherrima*, with the additional merit of having the coloured bract at least double its size, so that the effect a few well-grown plants of this species will produce may be readily imagined.

Sericographis Ghiesbreghtii comes next in order of merit as a winter-blooming plant, and should be grown in quantity where a constant supply of flowers has to be kept up at that season. Cuttings put in at once may be grown to useful-sized plants by the autumn if placed in gentle moist heat for a time, and potted on as they require it. Any old plants that have been saved should be pruned back and plunged in bottom-heat to induce them to break freely, after which they should be shaken out and re-potted as recommended for Poinsettias. Fibry loam, with a little peat or leaf-soil and sand, is the best material to grow them in, and when they get well hold of it, nip out the points of the shoots to force them to start again, in order that the plants may become well furnished below. The *Sericographis* will stand in a temperature of 50° to 55° in a dry atmosphere during the winter, and will continue in great beauty for at least three months.

Rivina humilis.—Where plants for table decoration are required during the winter there are few better subjects for the purpose than *Rivina humilis*, grown either as standards or in the bush form; standards having clean stems about a foot high, carrying round symmetrical heads, laden with racemes of their rich glossy scarlet berries, are exceedingly effective. Seedlings are best for the purpose, as they can be quickly run up to the necessary height, and are less inclined than plants raised from cuttings to branch out from the stems. The *Rivina* is quite an all-the-year-round plant, as it may be had in perfection at any season, by simply resting a few, and then starting them into fresh growth by pruning them in and re-potting. Where bush plants are required, cuttings are best for the purpose, as they are naturally more pendulous than seedlings and hang over the edge of a vase in the most graceful manner; 4-in or 6-in. pots are quite large enough to grow them in, as they are most persistent rooters, and will feed and do well on the commonest fare. To enable them to flower freely and set their berries, they should be placed on shelves, or in some light, airy position, and be well supplied with water.

Ardisia crenulata is likewise well adapted for similar purposes to that of the *Rivina*, and when well grown with a profusion of its Holly-like berries depending from the ends of its branches, it has a very pleasing appearance. Plants with single stems are preferable to any others, and these also are best raised from seed. To keep up a supply of suitable size it is necessary to grow a few fresh ones every year, discarding a similar number. The *Ardisia* is very liable to scale, and the plants should therefore be frequently looked over and cleaned.

Scutellaria Mocciniana should be extensively cultivated, as it is one of the most useful decorative plants it is possible to have, and a great improvement on the old *S. macrantha* that used to be so highly prized. The flowers of *S. Mocciniana* are at least double the size of the latter, of rich velvety texture and most brilliant scarlet colour suffused with a shading of yellow at the tips, which renders it very attractive. Any one fortunate enough to have old plants of this species should cut them back at once, unless they are well furnished with young wood at their base, in which case stop the ends of the shoots to induce them to break again and make a good bushy growth. Cuttings put in now will soon root and form stocky plants if stopped occasionally and grown on in strong moist heat. A light rich soil, such as loam and leaf-mould with a little thoroughly decomposed manure, is the best in which to grow them so as to push them on quickly out of the way of red spider, to the depredations of which insect they are very subject; to cope successfully with these insect-pests the plants should be grown where there is plenty of atmospheric moisture and be well syringed overhead, in addition to being properly supplied with water at the roots, which should never be allowed to become quite dry.

Begonias are a most useful class of plants both for summer and winter decoration, but for the former purpose, the stove varieties are now superseded by the many beautiful greenhouse kinds sent out within the last year or two, a few of which should be in every garden. If tubers of these be obtained at once and started in any cool house or pit, they will flower in June, and last in perfection till October. For winter blooming, *B. fuchsoides* is one of the best, either for table decoration in 6-in. pots, or for its cut blooms in cespines or flower vases, for which its gracefully drooping habit renders it especially adapted. *B. semperflorens Saundersi* somewhat resembles the above, and as its name implies, is a continuous bloomer, a habit that renders it a very desirable variety to cultivate. *B. nitida* is likewise a fine old kind that should be in every stove, as it affords quite a different shade of colour and may be had in flower at almost any season. *B. manicata* is quite indispensable for the winter, either as a pot plant or for cutting purposes, as a few sprays of this introduced among other flowers impart to the whole a most pleasing and finished appearance. Cuttings put in now will make plants sufficiently large for ordinary purposes, but if extra sizes be required, a few old ones should be kept for the purpose. To get *Begonias* to flower freely and keep them dwarf and stocky, they should be grown in positions where they can get light and air. Good turfy loam and 6-in. pots will suit to grow them to perfection, if well supplied with water during the summer.

Ananassa sativa variegata is most valuable as a decorative plant, and one that will stand in almost any position during the summer without injury. For table decoration, associated with *Dracenas* or plants of that class, it is exceedingly effective. For the development of its rich leaf-markings in the highest state of perfection it is capable of attaining, an abundance of light is necessary. The plants should therefore be placed well up to the glass and fully exposed, except just for an hour or two during the brightest part of the day. Six-in. pots are quite large enough for them, as they re-

quire but little room, and are more serviceable in that size than any other.

Pandanads are most useful plants as single specimens in vases, or as a decoration for the dinner-table, a purpose for which they are eminently suited, owing to the gracefully re-curved form of the leaves and the light elegant appearance they present. The smaller forms, such as *P. javanicus variegatus*, *Veitchii*, and *ceramensis*, are best adapted for such positions, but each should be confined to a single stem, instead of being allowed to throw out suckers, which greatly detract from its beauty. Any old plants with suckers should have them pulled off with the roots attached if possible, for the purpose of growing in small pots, and to be used for table decoration when properly established. These, like the Variegated Pine above alluded to, require abundance of light, and should receive similar treatment.

Curculigo recurvata variegata is a plant of noble aspect, having Palm-like foliage that renders it exceedingly ornamental; and as it will thrive in moderate heat, it is doubly valuable. Even the green form, *C. recurvata*, is worth growing for decorative purposes, and has a grand effect among Ferns or *Dracenas*, with either of which it associates well. For table decoration and similar purposes, it perhaps looks best when grown in 6-in. pots and the plant confined to a single crown, as then its gracefully arching leaves are seen rising from its base, and show off to great advantage. To have them of this character, any old ones should now be divided, and the young suckers taken off with as much of the root adhering as possible, potting them afterwards, and placing them in close heat for a successful start. These, if hardened off by-and-by, will be found exceedingly useful for the autumn and winter, to occupy positions where it would be unsafe to risk subjects of a more choice or less hardy nature.

Vincas are among the most useful of summer-blooming stove plants, and should now be growing freely. To insure dwarf bushy plants, let them have abundance of light, and nip out the points of the shoots to induce them to break back and become properly furnished. Any regulating or training that may be necessary should be done during the earlier stages of their growth, so that when they get into bloom they may lose that appearance of stiffness which is so objectionable in plants freshly tied. *Vincas* are rather gross feeders, and should therefore have a rich soil in which to grow, such as a mixture of fibry loam and well-decomposed leaf-soil, in the proportion of two-thirds of the former to one of the latter, with sufficient sand to keep it open. As established plants of these fill their pots with roots, they should be assisted occasionally by giving them weak manure-water, made from sheep manure with the addition of soot, which always imparts a rich deep green healthy-looking appearance to the leaves of any plant to which it may be applied in the above manner.

Cocos Weddelliana.—Where plants are in much request for table decoration, Palms are almost indispensable, and none are more light and elegant in appearance, or so well suited in every respect for the above purpose as *Cocos Weddelliana*, a perfect gem among the arborescens of vegetation. Unfortunately, the majority of other kinds soon get too large for table embellishment, but by keeping these confined to 6-in. or 8-in. pots, they may be preserved in perfect health for at least a couple of years, if well supplied with water at the roots, of which at most times they enjoy rather liberal supplies. *Areca lutescens* is a Palm of remarkably graceful habit, and comes next in order of merit to the above, and as it will stand in a cool stove or moderately warm greenhouse, it is a very desirable variety to cultivate. The yellow stems of this show a pleasing contrast with its delicately pale-coloured leaves, and give the plant a very striking appearance. There is one advantage in growing Palms for table decoration independent of their great beauty and general suitability for the work, and that is, they are constantly increasing in value for other purposes, such as the decoration of conservatories, halls, &c., for which no plants are more suitable or better adapted in every respect.

Caladiums have proved to be exceedingly useful for dinner table decoration during the summer months, but to get them to stand without flagging they must be prepared some time previously to being required. If allowed to stand in bottom-heat, or in a close damp atmosphere, they soon droop when exposed to the air of a room, and therefore, when of a sufficient size, they should be gradually withdrawn from it and placed in positions exposed to light so as to stiffen their stems and harden the foliage. Some of the more recent introductions, such as *Prince Albert Edward* and others of that class, having thick stiff *Alceasia*-like stems, are better adapted for the purpose than most of the older varieties, and should therefore be grown in preference, except it were to replace such delicately beautiful kinds as *C. Belleymei* and *C. argyrites*, two that are always special favourites. Those that are confined to small pots, or are getting well

advanced in growth with plenty of leafage, will now require liberal supplies of water, and a good syringing overhead when closing the house in the afternoon. *Caladiums* often receive more shade than is really necessary or desirable, as they are never so useful for standing in other positions out of the house in which they have been grown, as they are when they get more exposure to light, plenty of which is necessary to bring out and fully develop the beautiful leaf-markings for which they are so generally esteemed.

Campsidium, or *Capania filicifolia*, is a very elegant-habited plant, having beautiful Fern-like foliage, borne on light fragile stems, that give it a very graceful and pleasing appearance. This is well adapted for table decoration, and especially for baskets, or out blooms for apogones or tall vases of flowers, to hang down over the sides, in which position it is very effective. Old plants out back will soon start again, when the young tender growth should be taken off with a heel and struck in close moist heat to grow on for either of the above purposes. One or two planted out where they can have room to spread will afford abundant supplies for cutting, a purpose for which they are so highly prized.

Conservatory.

Camellias are likewise moisture-loving plants, especially while carrying their bloom and making their growth, which latter process they are in most cases now going through. It will, therefore, be necessary to water freely, so as to make sure of soaking the whole of the soil, otherwise the lower roots will suffer, and perhaps perish through lack of moisture, while the surface gives indications of being in proper condition. Dryness at the root is a frequent cause of *Camellias* shedding their buds, and therefore from now till the autumn it will be necessary to watch them closely to prevent them from getting into that condition. To assist them in starting their buds and to make a free, vigorous growth, they should be kept well syringed overhead every morning and evening, and a moist state of the atmosphere maintained during the day by damping the floors and other available parts of the house. Maintain a gentle, steady heat by closing early in the afternoon, by which means fires will not be required. *Camellias* object to strong sun-light, especially at this season of the year, and suitable shade is of the greatest importance in keeping the temperature regular and the air of the house in an equable state as to moisture.

Rhododendrons.—Among plants that should take a foremost position for conservatory decoration at this season of the year, the many beautiful varieties of hybrid *Rhododendrons* may be classed as the most showy and useful. The greater part of these come naturally into bloom in March and April without the aid of artificial heat, and are doubly valuable on that account. *R. jasminiflorum* is a perfect gem, and for spotless purity almost rivals the *Stephanotis*, the flowers of which it greatly resembles, except that they are even more waxy-looking and beautiful. The long stout tube and the great substance of the flowers render them of great value for bouquet making, for which their form and small size are well adapted. It is a plant that cannot be too extensively grown for the above purpose, and one whose merits it is impossible to praise too highly. *Princess Royal* resembles it in form, but has more colour, and is a good companion plant to cultivate with it. *Princess Alice* is a noble variety, having flowers almost as large as *R. Edgworthii*, and of great substance, which ensures them lasting a long time in perfection. The colour of the flowers is white suffused with pink on their outer surface; and, in addition to the above qualities, it is deliciously fragrant. *Princess Alexandra* is likewise a free-blooming handsome kind, well adapted for conservatory decoration. Countess of Hadington has fine large bluish-white flowers, and a dwarf, compact, free-flowering habit that renders it a very desirable variety to cultivate. *R. fragrantissimum*, as its name implies, is very sweet-scented, and partakes of the shrubby habit of *R. Gibsoni*, from which it was raised, with the delicious fragrance of *R. Edgworthii*, the pollen parent. Any one requiring really serviceable plants cannot fail to be satisfied with the above, which, if accommodated after the manner of *Azaleas*, will grow and bloom with the greatest freedom. These, with a few hardy hybrid varieties that may be lifted and potted when set with bloom buds, will go far towards rendering the conservatory gay with flowers, and take the place of *Camellias*. All that the choice hardy kinds require is some slight protection to any young tender growth they may have made while standing in bloom under glass, as when they are turned out too early they are apt to be injured and thrown back for a year.

Solanums.—As these become shabby from their berries shrivelling or the leaves falling from them, they should be cut well back, and have their branches thinned out, to give the necessary room for the young ones to take their place. *Solanums* will stand some amount of frost without injury, and they may therefore with safety

be planted out at once. Choose a situation fully exposed to the sun, but so that they can have shelter from strong winds usually prevalent towards the autumn—a time when they are little able to bear it from being so heavily laden with their ornamental berries. Planted out, they do not require a tithe of the labour as when grown in pots, while their capacity for blooming and fruiting is increased at least tenfold. The soil in which they are planted ought not to be rich, as when that is the case the plants are driven too much into growth, and fail to produce flowers in sufficient quantity to give them a full crop of berries. Young plants raised from seed or cuttings during the spring should be pushed on in gentle heat for some time to come, in order to get them as strong and large as possible before planting them out.

Richardia ethiopica is a most valuable subject as a decorative plant for winter, viewed either as regards its foliage or the numerous highly ornamental flowers it sends up. No place should be without a good stock of these, and now is a good time to divide and increase them, as each stem or crown will afford a separate plant. Secure with each piece as many roots as possible, and pot separately in light rich soil, after which place them where they can receive a moderate amount of heat for the purpose of giving them a start for their future planting-out. Plants already established may be turned out at once so as to give them a long season's growth, by which means they will produce a continuous supply of flowers all through the winter. If planted in shallow trenches, something after the manner of *Celery*, they can be easily watered during the summer, and, from their half aquatic nature, they take large supplies, and cannot be overdone in that respect. In preparing the trenches give a good dressing of half-rotten manure and place the plants 2 ft. apart, which will afford the necessary room for them to grow and acquire great strength of leaf-stem. Mulch over the surface with some light littery manure for the purpose of shading the roots and preventing evaporation, thus saving much labour in watering, besides keeping the plants in a more uniform state as to moisture. *Richardias* do well planted in shallow water, and are exceedingly ornamental in ponds or basins of fountains, positions for which they are well adapted. If planted or placed in pots so as to have their crowns about 3 in. beneath the surface of the water they will stand the winter and break up again from below. Any spare plants may therefore be advantageously employed for embellishing the above-named places, and so made to serve a useful purpose.—J. SHEPPARD, *Woolverstone Park*.

Orchids.

Examine baskets and blocks, beginning at one end and going through them, replacing them in such a way that the plants may not occupy the same positions that they did before; thus treated the plants themselves will be benefited, and they may be so arranged that those on the stages below which had plants hanging over them before shall be relieved; hang as many of the baskets and blocks as possible over the pathways, a row on each side so that the drip may not fall on the staged plants. Clean the plants by means of a sponge and some rain-water, unless they are infested with insects, in which case a little weak tobacco-water should be used. Re-basket any that may require it, and, in the case of others, work out the old material and re-place it with new. Take care that none of the leaves rest against the wire, as this will injure them, more particularly if the wire be not of copper, which is the only good wire for Orchid-baskets. Attend to the night temperature, and in the case of any of the houses in which it cannot well be kept down leave a very little top air on; this will rather benefit the plants than otherwise. It is surprising that so little attention is paid to the night temperature, for if it be allowed to get too high when the plants should be inactive, it injures them. Attend to cleaning and potting as directed last week, looking well after such plants as may have thrips on them; sponging them frequently with weak tobacco-water, one cleaning being of little use, as the young thrips soon reappear. See that no rubbish accumulates in any part of the house, for, if allowed to do so, it will harbour insects. Be careful in watering, using rain-water only for the purpose, and giving it to the plants in such quantity as the state of the growth may warrant; be careful, too, to prevent the water getting into the hearts of the young shoots. On cloudy mornings, when the sun peeps out only for a time, ventilate in order to keep the temperature right, and sprinkle the floors rather than let the blinds down, until you see if the day is to be sunny or not. Temperatures as given last week.—JAMES O'BRIEN.

Hardy Fruits.

Notwithstanding the inclemency of the weather and the sharp frosts of the 13th and 14th inst., accompanied by the heaviest fall of snow we have had in this district at any one time for years past, fruit trees do not seem to have suffered materially, and, as yet, there

is every prospect of a good fruit season. Apricots, however, have disappointed our hopes, and will be a very poor crop, for, although they bloomed profusely, many of the blossoms lacked vigour, a circumstance doubtless attributable to the immature state of the buds by reason of the excessive wet and sunless weather of last autumn. However, though there is likely to be but a scanty return in the shape of fruit this season, the trees must not be neglected on that account, as such a proceeding would also prove fatal to next year's crop; give them the same attention as if they were full of fruit. Keep a sharp look-out for the leaf-rolling caterpillar, which is specially injurious to Apricots, and if not taken in time will soon strip a tree of its leaves. I know of no remedy for its extirpation other than hand-picking, and this is never a very formidable task, as, if taken in time, an examination of the trees twice or thrice suffices to keep them in check the whole of the season. Pinch the new growths to two or three eyes, and rub off forefruit and other misplaced shoots; any young branches that are being trained up, if growing too vigorously, should have the points taken out, it being always desirable to equalise the flow of sap over all parts of the tree. Disbudding of Peaches and Nectarines can no longer be delayed without causing serious injury to the trees. My constant recommendation is that it be accomplished early; but if it have been delayed until the shoots are, say 4 in. long, I suggest that no disbudding whatever take place, but that in lieu thereof the shoots be shortened back to one eye or joint; innumerable fruit spurs are thus formed, and the growth of young wood is not nearly so vigorous but more fruitful. I have practised a modification of this plan for some time, and am well satisfied with the results. Thin the fruit as soon as the swelling can be discerned, and keep in check aphides by frequent syringings with soapy water, which should always be applied early on the mornings of fine days. Currants and Gooseberries are exceedingly well fruited this season, and blue aphides on Currants, and caterpillars on Gooseberries, will probably soon put in an appearance; the former may be got rid of by washing with clear water, or, what is preferable, soap-suds, which should be applied with some little amount of force—as through a syringe or garden engine. For caterpillars, no better method of riddance has yet been invented than hand-picking; a good preventive is to strew the ground beneath the trees with tanners' bark or quicklime. The cuttings of these that were recommended to be put in some time back should now be gone over for the sake of rubbing off all shoots or eyes, except two or three at the top; by this means nice clean stems are insured, which look, and indeed are much better than if the trees were allowed to branch out immediately above the soil; if through any cause they have become loosened, the ground around the base should be well trodden, otherwise they cannot root or make satisfactory progress. In fine weather surface-ice amongst all kinds of fruit bushes, to prevent the growth of weeds. Recently planted trees should be mulched, for after so much wet, as soon as dry weather sets in the soil is sure to crack, and this mulching assists to neutralise the bad effects that would otherwise ensue.—W. WILDSMITH, *Hockfield.*

Almonds.—In your remarks of last week (see p. 383) you do not mention the so-called Jordan Almonds of commerce, which are very largely exported to this country from Malaga, in Spain. They are the large kind eaten with Raisins at dessert, and are infinitely superior to all other Almonds with which I am acquainted. The finest brands sometimes fetch here as much wholesale as from £14 to £16 per cwt. Large quantities of shelled Almonds are sent to England from Barbary, and a few from Sicily, in addition to the shell Almonds from France. Altogether the Almond trade is an important one. The few kernels that ripen on London trees are often of excellent flavour, and if later-flowering kinds were grown here there is no reason why we should not have good crops of Almonds. It is strange that the Almonds eaten green in France and Italy are not imported here, as they form a delicious fruit, and would readily bear the short journey, even if we could not grow them ourselves. It is stated, but I do not know whether truly or not, that it is not known when Almonds are sown whether the fruit will prove to be sweet or bitter, and that the seeds from a sweet tree will often produce bitter fruit. If true, this fact is singular, but not more so, perhaps, than that some flowers of the same kind are scentless and others highly scented—Cyclamens being a case in point.—P.

Influence of Light on Grapes.—In the March number of "The Gardener" the editor remarks that while Lady Downe's Grape has usually a thick skin, and is deficient in flavour, yet when grown under the influence of as much light and air as it could possibly be subjected to in this country, in a large house, with a maximum of glass and a minimum of woodwork, the Grape in question assumes a thin skin and an excellent flavour; in fact, becomes a rich sweet Grape, with comparatively a thin skin devoid of toughness.

VEGETATION IN AUSTRALIA.

AUSTRALIA is a world by itself as regards vegetation, a lovely world of strange trees and blossom-laden shrubs. Often, when one kind monopolises large tracts, a kind, perhaps, not even furnished with a green leaf, the effect is monotonous to a depressing degree. Many of the trees, if distinguished for their stature or the value of their timber, are not so remarkable for the beauty or brilliancy of their blossoms; but many, on the other hand, are of surpassing loveliness and grace. Acacias alone are a garden of beauty in themselves—fountains of gold, and often with leaves like delicate Ferns. Full-grown Acacias, in all their glory of blossom, must be amongst the handsomest trees that grow. We have seen them in the gardens round San Francisco Bay, where they grow well, and also in Southern Italy, where some form medium-sized trees, but in their native land they are doubtless much finer. In our gardens we rarely get an idea of what an Acacia really is, seeing them in pots and trained as pillar plants. Many who train the delicately-out *A. dealbata* over a trellis have little idea of what it is—a well-furnished tree, 30 ft. high, smothered in blossom; and of the magnificent Gum trees we have still a smaller notion. We have never even seen photographs of the enormous trees described by Baron Mueller as larger than the Sequoias of California, and consequently probably the largest trees in the world. We have, however, seen many young Gum trees growing in a climate really suited to them (California), and, except the Birch, we have not seen any other trees equal to them for the grace of the growing shoots. Numbers of Australian plants are found quite at home in many parts of the northern world, happily for those who have gardens on the Mediterranean, and in many other regions. What a precious art is that which enables us to enjoy in Europe or Northern America much of the beauty of the Australian tree world! Australian vegetation is not so often praised for its luxuriance as that of other lands. Mr. Charles Moore, of the Sydney Botanic Gardens, informs us that in the mountains gullies sometimes are seen wherein the effect of a rich growth of tree Ferns, intermingled with other types of vegetation, is as richly beautiful as any aspect of vegetation to be seen in tropical lands: such a scene is that shown in our illustration.

The *Dracœna* as a Berry-bearing Shrub.—Hitherto *Dracœnas* have been valued for their leaves alone, but Mr. Wills (says the "Gardener's Magazine") has made a tremendous stride, not only in raising a new race, but in demonstrating the splendour of the plant when smothered with fruit. When recently looking over the nurseries at Anerley, we saw many large *Dracœnas* profusely laden with berries in various stages of development, in some cases quite green, in others fully ripe, and of a rich deep purplish-red colour. Here is a new feature for enterprising cultivators, and one that has a considerable attraction for such as aim at exhibition honour, for a group of well-berried *Dracœnas* would make a sensation, and to produce a crop of berries requires both skill and patience. The time of year at which the berries usually ripen is from late autumn to the turn of spring, but in a place where a large number of plants are grown they might be obtained at almost any season of the year. A few of the autumnal schedules have classes for berry-bearing shrubs, and we find in the competitive groups such plants as *Ardisia*, *Rivinas*, *Skimmias*, and *Solanums*, but henceforth we shall hope to see *Dracœnas* also, and no one better than Mr. Wills could show the way to success.—S. H.

Sparrows and Horse Chestnut Buds.—I have read some accounts in the "Field" of sparrows destroying Crows, but I have not observed it in this part of the country. However, last week, I "caught them in the act" of a much more serious destruction. Within ten yards of my window stands a Horse Chestnut tree, which during the first week of this month made rapid progress, the buds being 2 in. to 2½ in. long, but as yet unopened. Owing to frost, snow, and cold weather during the buds being bunched—by the frost, I presume. Well, last week I discovered numbers of house sparrows, which take shelter in an Ivy-covered wall close by, attacking the buds: their mode of procedure was to nip off two or three leaves, let them fall on the ground, and then to take one peck from the inside of the bud, which seemed to satisfy them with that particular bud, as they forthwith commenced upon another.—CHARLES W. COWAN.

ASPECT OF VEGETATION IN THE MOUNTAINS OF AUSTRALIA.

TREES AND SHRUBS.

DENDROPHILIA :

OR NOTES FOR PLANTERS, ESPECIALLY ON EXPOSED SEA-COASTS.
By SALMONICEPS.

(Continued from p. 318.)

Picea.

This family contains some of the grandest and most beautiful trees in the world; indeed, all the Silver Firs are so attractive, that the only way to be guided in making a selection from them is to ascertain the hardness of each species—a quality in which, under our skies, some of the finest are rather deficient. Our practical knowledge of some of the Californian species is at present limited, owing, as in the case of *P. amabilis*, magnifica, concolor, and others, to the difficulty of getting a supply of good seed. The seeds are generally devoured before reaching this country by a maggot, which is hatched from an egg inserted when the cone is young and soft. Enough is known of these species, however, from the accounts of travellers, and from the few seedling specimens in this country, to stimulate collectors to do their utmost to obtain a good supply for the benefit of our grandchildren.

PICEA NOBILIS.—Fortunately this splendid tree is becoming tolerably common in this country. In all collections it is the most conspicuous of the Silver Firs, and promises to be a useful forest tree. It is very hardy, of rapid growth, and although it is not advisable to place it in immediate exposure to the sea-blast, yet it agrees well with a marine climate, and stands ordinary storms well.

PICEA NORDMANNIANA.—If *P. nobilis* be the best of the new Californian Silver Firs, this is undoubtedly the finest of the European or Asiatic species. It is likely at no distant date to supplant the common Silver Fir for ordinary planting; the timber being of better quality, and as it starts later in growth it is less apt to be injured by late frosts. Its growth is rapid and symmetrical, and the foliage of a bright grassy green, which has a very cheerful effect in mid-winter. It behaves well in exposure, though the writer has had no opportunity of studying it as a sea-side tree. The colour of this tree varies at different hours of the day; the leaves, which in sunshine spread out and show the green upper surface, curve upwards when the sun is off them, and show the silvery lining.

PICEA PINSAPO.—Although eclipsed in stature by those just named even this limited list would be incomplete without this hardy and singular Fir. It is rather as an ornamental than a profitable tree that it should be planted, and although its growth is slow it should be allowed plenty of room and depth of soil to develop its peculiar character, which consists in extreme density and rigidity. The prickly short foliage distinguishes it from all other Firs.

PICEA LOWIANA (*lasiocarpa*) is a large Californian tree, which, from its late growth, is perfectly hardy in Britain. It seems, however, not to thrive in any but deep soils. Where such are available, with moderate shelter, it is a desirable and distinct tree.

Pinus.

The true Pines are probably useful to man in more ways than any other family of trees. While most species produce splendid timber, others produce food in great abundance; and the gums and juices of many sorts are imported articles of commerce. Our only native Conifer which attains the stature of a forest tree—the *Pinus sylvestris*, the Scotch Pine—belongs to this group, and, indeed, none of the new introductions are more truly beautiful. But there are many foreign species so grand and valuable that no collection or woodland should be without some of them.

PINUS AUSTRIACA (the Black Austrian Pine) is too well known to require much recommendation. It is an excellent sea-coast tree, and the rich massive foliage preserves its somewhat sombre but healthy green in all situations. It should be planted in masses, as when isolated as a specimen, or standing singly among deciduous trees, it is rather apt to be overturned by storms, because the roots are rather spreading than descending, and the head of the tree becomes very heavy and branching.

PINUS LARICIO (the Corsican Pine), which resembles the last

species in many respects, but is distinguished from it by more rapid growth, and by the twisting of the foliage, is a valuable forest tree, and one which has gained a good reputation. It is a good tree to plant in exposure, and is not particular about soil, appearing to thrive equally well in heavy clay and in thin poor soils. It is the last of the Fir tribe that rabbits will attack, no mean point in its favour.

PINUS BENTHAMIANA.—Although thirty years have elapsed since this magnificent tree was first brought to this country, it does not seem to have become as popular as it deserves. The timber is most valuable, and grows to an enormous size on its native mountains, reaching a height of 200 ft. and a circumference of 28 ft. It is perfectly hardy in this country, and very ornamental from its long heavy foliage and bold habit.

PINUS INSIGNIS.—This is a real sea-side beauty. Of all the true Pines the greenest, and in mild districts the most rapid in growth, it is all that can be desired as an ornamental forest tree. In high cold districts it is not very hardy, from its habit of making a second growth in autumn.

PINUS RADIATA, which comes from the same hill-sides as the last species, bears a high character for beauty and usefulness, and will probably prove harder than *P. insignis* in inland districts, but the writer cannot speak of it from experience. *Pinus Coulteri* also grows within sight of the Pacific, and being very hardy, it should be sought after.

PINUS CEMBRA (the Arolla or Swiss stone Pine), is well known to Swiss tourists. Although of a somewhat gloomy colour and formal habit, and rarely growing more than 50 ft. high, this tree obtains a place in the list on account of its extreme hardness. It should be planted in high exposed situations, where many other kinds would perish. The well-known Swiss carvings are made principally of the wood of the arolla, which is soft and easily worked.

PINUS EXCELSA (the Bhotan Pine).—This tree resembles the last as an Arab steed resembles a Shetland pony. It is quite hardy in this country, but dislikes extreme exposure. It well merits a sheltered place, where the beauty of its silvery, silky foliage may be fully displayed. For that beauty alone, if for no other, it is worth growing, realising, as it does, Virgil's eulogy on the Stone Pine—"Fraxinus in sylvis pulcherrima, Pinus in hortis" (the Ash is most beautiful in the woods, the Pine in gardens).

PINUS MONTICOLA.—A fine hardy tree from California, intermediate in appearance between the *Cembra* and *Strobus*, but excelling both in beauty, and to be preferred to either in this country. It does well on poor, rocky soils, and though slow of starting, grows rapidly when well established.

PINUS STROBUS.—The Weymouth Pine has been long enough naturalised in this country to make it a tolerably familiar tree in the landscape. It has not justified the expectations formed about its use as a timber tree on this side of the Atlantic. There are, however, in various parts of the country fine specimens of it attaining a height of 80 ft. or 90 ft.; but it is not in every country that the conditions of soil and climate combine to produce the tree of that size. It prefers a sheltered situation and a deep gravelly soil, and is especially impatient of the sea-blast. The last-named species is more likely to be a profitable tree in exposure; but the beauty of the Weymouth Pine is such that it should not be discarded where circumstances are favourable to its growth.

It is difficult to leave the true Pines without naming a few more of the very attractive kinds that have been brought to this country; and it is only from strict regard to the principles observed in framing this list that no more than the ten above-named species are included in it.

Araucaria.

ARAUCARIA IMBRICATA.—The Chili Pine or Monkey-puzzle is only now attaining the stature of a forest tree in this country, although introduced as long ago as 1795. It is only when it reaches a height of 30 ft. and upwards that the true character of the tree begins to appear; it becomes then extremely graceful from the pendulous sweep of the heavy branches. Under that age it is a formal, rigid, and rather ungainly tree. It is extremely impatient of the proximity of other trees, and should always have free light and air all round. This peculiarity will always hinder the general use of it as a

forest tree, even if the timber turns out in this country as valuable as it is reported to be in its own. It is perfectly hardy, and stands considerable exposure, agreeing with the immediate neighbourhood of the sea. It does not appear particular about soil, and, although it is said to dislike damp, I know instances of its growing vigorously in peat which contains water at 2 ft. or 3 ft. below the surface. It is a dioecious tree, therefore when cones are produced it is necessary, in order to fertilise the seed, to dust them with pollen from the flowers of the male tree. The first trees raised from native seed in Scotland were grown in 1874 from cones on a tree 28 ft. high, at Castle Wigg, in Wigtownshire.

Cedrus.

CEDRUS ATLANTICA.—Each of the three Cedars known and introduced to this country, are such beautiful and majestic trees, and agree so well with this climate, that it is impossible to exclude one of them from the most limited list. Indeed it is hard to say which of the three is preferable. The Mount Atlas Cedar seems to be the most rapid grower. Introduced in 1843, there are already specimens 50 ft. high in different parts of the country. Although a native of Africa, it is perfectly hardy with us. It requires a well-drained soil and moderate shelter.

CEDRUS DEODARA.—The graceful beauty of this tree when young has taken the popular fancy in a greater degree than almost any other Conifer. It is indeed a beautiful tree at all ages, and where a well-drained site can be obtained, it may be confidently planted as a timber tree. Its growth in this country is somewhat slow, though quicker than that of the next species. It is not adapted for sea-side planting.

CEDRUS LIBANI.—The Cedar of Lebanon is known to us in this country from many stately specimens which we possess. It was introduced about 200 years ago, but its use has been confined to ornamental purposes, as it seems never to have been employed as a forest tree. Some of the old specimens which stand in gardens bear signs of maltreatment, which they have received when young, in the endeavour to keep them in a shrub state, showing singular want of discernment of the true character of this tree, which, though far from the tallest, is certainly as majestic as any tree in the world.

Cupressus.

Among the true Cupresses are ranked some of the most beautiful and stately trees in the world; they are remarkable from being conspicuously beautiful when only a few feet high, a quality in which many forest trees are somewhat deficient. In this list will be found only those which attain the stature of a forest tree, and which have proved themselves of undoubted hardness in this country.

CUPRESSUS LAWSONIANA.—The Lawson Cypress is, perhaps, the gem of the group, promising at the same time to rank as one of our most valuable forest trees. It requires some shelter from high winds in order to develop its foliage properly, but it is proof against any amount of cold that it is possible to encounter in an English winter. It is not particular as to soil, but requires good drainage. Unlike the next species, it is not adapted for maritime planting.

CUPRESSUS MACROCARPA (the Monterey Cypress) is an invaluable tree for sea-coast planting. It should be securely staked when planted in exposure, as the annual growth is rapid and spreading. This Cypress has not proved hardy in high inland districts, and should not be planted except near the sea-coast. It is very ornamental, of graceful form, and unchanging bright green. From some unexplained cause, I have found that more plants are lost after planting in this than in any other kind of Conifer. All Cupresses transplant better in May than in any other month, provided this can be done without keeping them long out of the ground.

CUPRESSUS SEMPERVIRENS.—This is the Upright Cypress, so well known on the shores of the Mediterranean; and though only known in this country as an ornamental tree, yet its timber is considered more durable than any other in the south of Europe. Its requirements in this country are a well-drained soil and a sheltered though airy situation, and in these particulars it is exigent. Under such circumstances it is hardy in this country, and as valuable as ornamental timber can be, but it cannot be called robust under such conditions.

CUPRESSUS NUTKAENSIS.—Known for long as *Thuopsis borealis*, this is a tree of great beauty and rapid growth. It is perfectly hardy, not particular as to soil so long as the site is well drained, and is one of the most distinct and effective trees for park planting. The timber is not likely to be of any great value in this climate. Moderate shelter should be afforded to this species.

CUPRESSUS TORULOSA.—I felt some doubts about placing this species in the list, as it bears a doubtful character, according to Mr. Gordon, for hardness, but I have had the opportunity of observing fifteen trees of this species for nearly twenty years on the west coast of Scotland, where they have remained totally uninjured by frost, and have been yearly increasing in stature and beauty, therefore it finds a place here, being one of the most distinct Cupresses we have. The trees above alluded to are from 15 ft. to 18 ft. high. Its growth in this country appears not to be very rapid. In northern India it attains an immense size, and the timber is considered equal to that of the Deodar. A well-drained site is indispensable; about other conditions of soil it appears somewhat indifferent. It has a very rich effect in lines or masses in gardens or kept ground.

Juniperus.

There are many handsome kinds of Juniper, but few attain the size of trees. Of our two native species, *J. communis* is a beautiful shrub, especially the upright Irish form (*J. communis hibernica*); the other (*Juniperus nana*), if, indeed, it be a species, and not merely a variety, is a very dwarf creeping bush. The first-named attains the size of a small timber tree in France, but in this country I do not recollect to have seen it higher than 15 ft. Of *Juniperus religiosa* (the Nepaulese Incense Juniper) I cannot speak from experience, but, from the description given by those who have seen it on its native hills, it must be a fine tree and worth looking after, for it grows to a height of 60 ft. to 80 ft., and produces good and very durable timber.

JUNIPERUS VIRGINICA (the Red Cedar) is a very hardy tree, and admirably adapted for dry sandy soils where many trees would fail to grow. It has been long established, and is thoroughly hardy in this country, but is not specially suited for resisting high winds. It has of late been extensively planted in the Black Forest, to supply wood for the pencils for which the lead is there mined.

Libocedrus.

LIBOCEDRUS DECURRENS.—The beauty of this *Arbor-vitæ* is so remarkable, that it is worthy of every effort to establish it favourably. Although growing to a large size in America, it has not attained any great size during the twenty years since its introduction to this country. Its growth appears to be slow; still, it is probable that a deep well-drained soil in a sheltered situation will cause this plant to grow into a very ornamental and distinct tree. In California it is known as the White Cedar, and in English nurseries is generally mis-named *Thuja gigantea*.

Salisburia.

SALISBURIA ADIANTIFOLIA.—The Ginkgo grows to an immense size in China and Japan; but it is not as a forest tree that it claims a place here, but on account of its singular dissimilarity from all other Coniferous trees. One or two specimens, at all events, should be included in any considerable collection, as it is decidedly ornamental as well as singular. The deciduous, leathery leaves, shaped something like those of a Maiden-hair Fern, distinguish it at once from any other of the Fir tribe.

Ivy on Stakes.—The plan adopted at Kew of growing some of the smaller varieties of Ivy on one or three stakes under 4 ft. high is a good one under various circumstances. A plant occurs between every two beds; three stakes meeting at the top look better than one. It is probable Ivies may be kept more satisfactorily in this manner than arranged on a wall, where they frequently grow together. The effect of the plants grown in this way is very good; for the sake of securing permanence in the supports iron stakes would probably be the best.—V.

Magnolia Soulangiana.—This is a fine showy flowering shrub. When planted on a south wall it grows freely, and flowers in a young state. The blooms are very hardy, having withstood the snow and frost of last week with little injury.—A. H., *Thoresby, Notts.*

SEED SOWING.

Now that favourable weather has at last set in, seed sowing will be an important operation. The first consideration should be to obtain good seeds, and those who have but little experience should invest their money cautiously in a few of the more hardy and popular kinds. Half-a-dozen good plants well cultivated, will give more pleasure than twice their number neglected. Always be careful to get seeds, suited to the purposes for which they are intended. If a climber be desired to cover a fence or trellis, the Morning Glory, the climbing Nasturtium, and similar plants will give satisfaction; while some of the more tender climbers will not be likely to come up if planted in such a situation as this, and if they do happen to grow, will not cover the place designed for them, and disappointment will be the result. If the object be a brilliant, showy bed on the lawn or in the border, the Petunia, Phlox Drummondii, Verbena, &c., will meet one's wishes; while a bed of Mignonette, or any of the smaller or less showy flowers, would be entirely out of place. If flowers of taller growth be desired for a showy bed more in the back-ground, the Zinnia, the French Marigold, Datura, &c., are admirably adapted, while some very beautiful dwarf-growing flowers would be worthless; even good flowers are sometimes condemned merely because they are out of their proper places. For instance, it would be wrong to sow Calceolaria and Cineraria, and other very delicate seeds, in the open ground and in soils where a Cabbage would hardly condescend to grow. The best soil for most flowers, and especially for young plants, and for seed-beds, is a mellow loam, containing so much sand that it will not bake after hard showers. If we have not such a soil, we must, of course, use the best we have, and as but little success is to be anticipated with delicate seeds in a stiff, clay soil, advantage must be taken of the various plans to ensure their proper germination. It is useless to try to grow good flowers on a poor, or a hard, unbroken soil, or in a bed choked with weeds. In either case the plants become dwarfed, arrive at maturity too early, and flower and ripen their seeds before they have attained half their natural size, and about the time a good robust plant would be forming its buds. Such

Flower-pot Protections.

a soil can be much improved by a little sand, or ashes and manure, and by pretty constant working. It must not, however, be handled when too wet. The flower garden should always be so drained that no water will stand on or near the surface. The manner in which seeds are sown is another important matter, and one in which beginners are most likely to fail. One "forget" may ruin a whole sowing of the choicest seeds. Of course, there are some kinds of seeds that are robust and that will grow, no matter how they are treated; but others require careful treatment. Many seem to think that seeds will grow anywhere and under any circumstances. They have learned that seeds of some trees and plants will grow without planting and care; and from these facts they get the idea that it is of little importance how or where seeds are sown, provided they are in the ground. But it should be considered that such seeds are usually larger and produce stronger and more robust plants than those used in the garden, and that thus they are enabled to bear more hardships and to live under more unfavourable circumstances. Another fact should be remembered—that not one seed in a thousand matured by our forest trees and shrubs produces a living plant. A forest tree will produce seed enough for an acre of closely set plants, and perhaps not a dozen will grow. We cannot afford to purchase costly seeds and lose such a large proportion, which we shall do if we plant in the same manner. If cultivators would be satisfied with only the most hardy and prolific flowers, such as would take care of themselves, then they might pursue a careless system of planting and cultivation, and fill their grounds with plants; but they crave for flowers that are not natural to our climate—those that flourish in warmer climes and under more genial skies—their dazzling beauty, their delicious fragrance, must be secured at almost any cost of time and labour. This is all very well; but having made up our minds to possess such treasures, we must pay the price—we must study their habits and treat them accordingly. A hot-bed, if properly managed, is of great aid in effecting the germination of seeds, and it is well that all should know why this is so, for there are many cases of failure as well as of success. If seeds be planted too deeply, they either rot in the damp cold earth, for want of the warmth necessary to their germination, or, after germination, perish before the tender shoots can reach the sun and air. If the soil be

stiff clay, it is often too cold at the time when the seeds are planted to effect their germination; for it must be understood that warmth and moisture are necessary to germination. Neither of these will do alone. Seeds may be kept in a warm, dry room, in dry sand or earth, and they will not grow. They may be placed in damp earth, and kept in a low temperature, and they will most likely rot, though some seeds will remain dormant a long time under such circumstances. Place them, however, in moist earth, in a warm room, and they will commence growth at once. Indeed, if seeds become damp in a cold store room they rot, while if the room be warm they germinate, and thus become ruined, so that seedsmen have to exercise great care in keeping their seeds well aired and dry. Another difficulty with a heavy soil is that it becomes hard on the surface, and this prevents the young plants from "coming up;" or if

Box Hand-glass.

Ordinary Hand-glass.

during showery weather they happen to get above the surface, they become locked in, and make but little advancement, unless the cultivator is careful to keep the crust well broken; and in doing this the young plants are often destroyed. If stiff, the soil where fine seeds are sown should be made mellow, particularly on the surface, by the addition of sand and light mould. If seeds be sown in rough, lumpy ground, a portion of them will be buried under the clods, and will never grow; and many that start, not finding a fit soil for their tender roots, will perish. The soil, we will suppose, is well prepared, fine as it can be made, and of that loamy or sandy character best fitted for small seeds. We will suppose, too, that the seeds were sown on the surface, with a little earth sifted over them, and that this was not done until the season was so far advanced as to furnish the warmth necessary to secure vegetation. Under these very favourable circumstances many seeds will grow; and if the weather be both warm and showery few will fail. But if, as is very common at the season of the year when we sow our seeds, we have a succession of cold rainy days, many of the more tender kinds will perish. A night's frost will ruin many more. If however, the weather should prove warm and without showers, the surface will become very dry, and the seeds, having so slight a covering, will be dried up and perish as soon as they germinate, and before the roots attain sufficient size and strength to go down in search of moisture. Of course, the finer and more delicate seeds, and those natural to a more favourable climate, suffer more than those that are more robust. In order to overcome these evils, glass must be employed. By being protected at the sides and ends with boards, and covered with glass the moisture which rises from the earth is confined, and thus the atmosphere is kept humid and the surface moist, and the plants are not subjected to changes of temperature, as a uniform state can be maintained, no matter what the weather may be. The bottom-heat,

Bell-glass or Cloche Protections.

if any, warms the soil, and enables the grower to put in his seed early, and obtain plants of good size before the soil outside is warm enough to receive the seed. Care, however, is required to prevent scorching the young plants. In bright days, the heat is intense inside the frame, and unless air is freely given, or some course taken to obstruct the rays of the sun, most likely a great portion of the plants will be ruined. Some time ago I was called to examine a hot-bed, as the seeds planted did not grow, when I found they had been all burned up, except a few along the edges that were shaded by the sides and ends of the frame. When the sun gets pretty warm, give the glass a thin coat of whitewash. This gives a little shade, and, with some air during the middle of bright days, will make all safe. A hot-bed is readily made by forming a pile of strawy horse-manure and leaves, some 3 ft. in height. It may be sunk in the ground 12 in. or 18 in., or made on the surface. On this set the frame and

place in it about 5 in. of good mellow soil, keeping the frame closed until fermentation takes place and the soil is quite warm. After this wait a day or two, and then sow the seeds. The principal advantages of a hot-bed may be secured by what is called a cold frame. This is simply a hot-bed frame and sash placed upon a bed of fine, mellow earth, in some sheltered place in the garden. By the exclusion of air and the admission of sun-heat, the earth becomes warm, and the moisture is confined, as in the hot-bed. After the frame is secured in its place, a couple of inches of fine earth should be placed inside, and the frame closed up for a day or two before the seeds are planted. As the cold frame depends upon the sun for its warmth, it must not be started as soon as the hot-bed; late in April is, in fact, soon enough. Plants will then be large enough for transplanting to the open ground, as soon as all danger from frost is over, and, as a general rule they will be hardier and better able to endure the shock of transplanting than if grown in a hot-bed. A frame of this kind anyone can manage. Watering occasionally will be necessary; and air must be given on bright, warm days. Shade also is necessary. Such frames, when so small as to be conveniently moved by the hand, are called hand-glasses. A simple frame or box, with a couple of lights of glass on the top, will answer every good purpose, though when small it would be better to have the front of glass. A very good hand-glass is made of a square frame, with a light of glass at each side and on the top. These contrivances, though so simple as to be made by any one handy with tools, are exceedingly useful, as they prevent the drying of the surface of the ground, and afford the plants shelter from sudden changes of temperature. Seeds may be sown indoors in pots and pans, but the greatest difficulty is that in these the soil dries very rapidly, and the young plants are apt to suffer. Under such circumstances a good plan is to cover the pots with glass, removing it occasionally for air and watering. Where very fine seeds are sown in pots, the watering, unless carefully done, generally results in great injury. A wet paper placed over the top of the pot will afford moisture enough for the germination of fine seeds. If pots be used, it is well to sink them to the rim in a box of Moss, or something of the kind that will hold moisture, and prevent the drying of the earth in the pots. A shallow box may be used to advantage, sowing the seed carefully in narrow drills. Where these conveniences are not to be had, make a bed of light, mellow soil in a sheltered situation in the garden; and as soon as the weather becomes settled, and the ground warm, sow the seeds, covering them with a little fine earth, and if very small sift it upon them. Some one has given as a rule that seeds should be covered twice the depth of their own diameter; that is, that a seed one-sixteenth of an inch through should be covered one-eighth of an inch. Perhaps that is as nearly correct as any general rule can be. If the weather should prove dry after sowing, it would be well to cover the beds of very small seeds with damp Moss, or what is better, with evergreen boughs or boards, or something that will afford partial protection from the sun and wind. A good plan is to nail laths on a frame, leaving the open spaces about as wide as the lath. Seeds do not require light for their germination, and will grow quite as well in the dark as the light until they are above ground. Bell-glasses are convenient both for in-doors or garden use, only care must be given to afford plenty of air, especially on bright days, and shading may be necessary. An inverted flower-pot answers almost as good a purpose, but when the young plants are up they will need light, which can be afforded for a few days and until the plants are large by elevating the pot, as shown in the accompanying woodcut. Light and air should be furnished as soon as the plants are above ground, or they will become weak and pale. Of course, it is designed that plants from a hot-bed, cold frame, and seed bed shall be transplanted to the border or beds where they are to flower, and these helps are intended mainly for what are called half-hardy annuals. Hardy annuals may be sown where they are to flower, but, with the exception of a few varieties difficult to transplant, it is best to sow all in a seed-bed. Seeds of certain hardy annuals and perennials may be sown in September. The produce is thus enabled to make vigorous growth early in spring, and to become well matured before the heat of summer sets in. After plants in the seed-beds have obtained their second leaves and have made an inch or two of growth, they should be transplanted. This should be done on a dull, showery day, if possible; if not, the plants may require shading after removal until they have become established. In transplanting in dry weather, always give the plants as they stand in the seed-bed a good soaking with water, and also the soil to which they are to be removed, an hour or so before removal. In removing, disturb the roots as little as possible. If the plants be not too thick, there is no need of injuring the roots; and in sowing, it is well to bear this in view, and to sow evenly and thinly. As soon as the young plants come up, if too thick, a portion should be removed. A few plants, with long tap-roots, will not bear removal well. The Larkspurs are

difficult; and these and Poppies, and plants with similar roots, should be sown where they are to flower. Still, there are few plants that cannot be removed when young, with proper care. Sweet Peas, Candytufts, and a few flowers of similar character, that do best if sown as early as the ground can be got ready, should always be sown where they are to flower. JAMES VICK.

THE KITCHEN GARDEN.

SEEDLING POTATOES *v.* THE DISEASE.

I SEE that Mr. Torbit, of Belfast, has again started the theory that seedling Potatoes will resist the disease if the experiment be carefully and repeatedly performed. Now, I believe some of our largest growers of Potatoes have taken the greatest care in trying seedlings with the older sorts in seasons when the disease was prevalent, and have found that they were attacked all alike ever since 1846. I have raised many thousand seedlings myself (some of them from the wild varieties of Chili and Peru), and I have not found one of them to be disease proof. The only chance of producing disease-resisting Potatoes is to raise them from varieties with red leathery skins and strong woody haulm, such as the Red Skin Flour-ball and scarlet prolific kinds. All kinds of Potatoes degenerate after they have been in cultivation a certain number of years, and it is only by raising seedlings that we can get vigorous new sorts, to be again superseded by others. All our very best table varieties with thin white skins, such as the Lapstone, Fluke, and Regent, are most subject to disease in wet seasons, and seedlings raised from them inherit the same propensity; the only safe way yet known of preventing loss in our Potato crops is to plant, as early as the season will permit, the earliest ripening varieties of the early and second early sections, so as to have them ready for lifting before the disease appears in July and beginning of August. The life history of the Potato fungus (*Peronospora infestans*) is now being investigated by Mycologists, and practical men will have to wait to aid them by experiments in finding out some way of destroying it, if found to rest in the tubers or soil; or, what is most likely, the resting spores may winter in other plants, and be diffused in the air when the temperature suits their development. A great run has lately been made on new high-priced American Potatoes, but the majority of them, when grown in this country, have an objectionable flavour as far as table use is concerned. They are, however, very prolific, and possess early ripening properties, and they may be the means, by hybridization, of improving English-grown kinds, as regards short-growing haulm and early ripening; but as respects the disease, they are quite as liable to it in bad seasons as English varieties. W. TILLEY.

TRUFFLES.

M. A. GEOFFROY SAINT HILAIRE, the President of the French Acclimatization Society, recently read a letter before that body, giving some interesting details on the subject of Truffles. The letter is dated Romans, in the department of the Drôme, in Dauphiny, the head-quarters of the Truffle trade. Truffles are hunted for throughout the winter by means of dogs specially bred and broken in for the purpose, and afford profitable employment to labourers in these parts, who at that season of the year have little or nothing else to do. The best strain of Truffle dogs is that known as "Chiens de la Bois," or the wolf-dogs, popularly known as "Louious." The dogs must be broken in fasting. They are given Truffles, of which they are very fond, several days in succession, after which these dainties are hidden in various places, and they are made to find them. A good Truffle-hunting dog will fetch £5 or £6. During the discussion which ensued with reference to this letter, M. Cosson stated that in certain localities in the neighbourhood of Paris, Truffles were found in the woods, and specially trained dogs were employed for hunting them. At Etampes and at Nemours Truffle dogs were used as in Dauphiny, and this kind of sport, if such it can be called, formed a very profitable and attractive occupation. As proved by M. Chaton, it is only in calcareous soils that we must look for Truffles, and in young Oak plantations of ten or twenty years' standing, as old Oak woods produce but a meagre supply. M. Vavin remarked that it was not only in Oak woods that the Truffle must be looked for, for last year in his own neighbourhood, in the Valley of Montmorency, he had seen large quantities dug up under Mulberry trees. M. Lichtenstein said that at Montpellier Truffles were found under various kinds of trees, especially under the Laurustinus. Dogs were sometimes employed to hunt them out, but pigs were generally preferred, as they showed more aptitude, and would hunt the whole day without tiring. M. Millet reminded his hearers that he had repeatedly called attention

to the fact of the Truffles being found under other trees besides the Oak. The Truffle was at one time considered to be a kind of gall produced amongst the roots of the Oak by the puncture of an insect; but it is now well known to be a subterranean Cryptogam, whose growth was encouraged by the shade of trees. At the next meeting of the Society, Mr. Yavin laid before the members a specimen of Truffles found at Besançon, Seine-et-Oise, in the park belonging to Madame Clerget. These Truffles were of excellent quality, and closely resembled those of Périgord. They were nearly all black, and marbled with white veins. They were found under Mulberry and Hazel Nut trees in large quantities. The end of October, when this gathering was made, appears to be the most favourable season for the purpose. At this period the Truffle has its full flavour, and has not suffered from the damp caused by November fogs.

T. L.

Conover's Common Asparagus.—My experience of this variety is, that one-year-old plants of it were nearly, if not quite, as large as two-year-old plants of the common variety, sown at the same time and in similar soil. Now, however, when the plants of each sort are four years old, I can perceive but little, if any, difference in the size of the heads of the two sorts; but the stems of Conover's variety appear to be of a somewhat brighter green than those of the common sort. I think that Conover's may be confidently expected to come into use one year sooner than the common sort.—P. GRIEVE, *Culford Hall, Bury St. Edmunds.*

Model Potato.—This is well known as one of the very handsome of white round Potatoes, and it is a large cropper. Its table quality is not first-rate, but it improves by keeping. It is not only almost the very latest Potato to start into growth in the spring, but it is equally late in ripening, and, best of all, it is later in pushing growth in the store than any other kind with which I am acquainted. I kept a quantity of it in a large tub all the winter, and although untouched at the bottom for five months, it has not pushed in the least. It is well worthy of cultivation on light soils for use through April, May, and June.—A. D.

Birmingham Potato Show.—It may interest exhibitors of Potatoes to know that the Council of the Birmingham Cattle Show have again decided on offering good prizes for Potatoes, to be competed for at the great Show at Birmingham in December next. The experiment made last year of arranging classes for "types of kinds" was so thoroughly successful that it has been decided to continue it. Thus Ashleaf Kidneys, known by innumerable synonyms, are to be exhibited in one class; for Lapstone Kidneys, which are also known by a number of names—*e.g.*, Haigh's Seedling, Pebble White, Hedley's Nonpareil, Yorkshire Hero, &c.—another class is set apart. Regents or Dalnaboys, or any variety of this class or type, no matter by what name known, are provided for in another class. Classes are also provided for (1) Paterson's Victoria, (2) Vermont Beauty or Brownell's Beauty, (3) for Snowflake or other white-skinned American variety, including Breese's Climax, Breese's Peerless, American Breadfruit, Early Goodrich, &c.; (4) for "any white-skinned variety not provided for in the other classes," and (5) for "any coloured-skinned variety not provided for in the other classes." There are also classes for three, six, and twelve varieties respectively, choice of sorts being left entirely to exhibitors, and in the latter twelve varieties the prizes are so good that the competition cannot fail to be large, for in addition to £5, £3, and £2 for first, second, and third prizes in money, a cup value ten guineas will be awarded to the winner of the first prize. Other valuable prizes are also offered: A list will shortly be ready.—B.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

The Turban Squash.—A correspondent informs us that the Turban Squash thrives admirably in his garden in the suburbs of London. He finds it an agreeable addition to his vegetable stores in autumn, and it keeps throughout the winter. Some of our readers, thus encouraged, may be induced to try this variety.

The Best Broccolies.—Among the many varieties, which we are growing this season, none comes up to Excelsior and Leamington. One late kind which I got from Messrs. Harrison, of Leicester, for trial, not yet in, is a perfect rival with fine large leaves which lie close to the ground. I cannot help thinking that this will be a good addition to late sorts.—R. GILBERT, *Burgley.*

Asparagus without Digging or Forcing.—This "Gardeners' Monthly" gives an instance of a remarkably fine yield of Asparagus occurring in a case where, after planting on the level ground, there was no culture of any kind beyond adding 2 in. or 3 in. of rich mould over the surface yearly. The bed was never dug over with fork or spade: This approximates to the French mode of culture.—V.

TRIAL OF BEDDING PANSIES AND VIOLAS AT GHISWICK IN 1875.

THE varieties of these plants subjected to the test of trial were contributed by Messrs. Dickson & Co., of Edinburgh; Messrs. Cocker & Sons, of Aberteeth; Mr. B. Dean, of Baling; Mr. G. Westland, of Witley Court; Dr. Stuart, Messrs. Milligan and Kerr, and Messrs. Robertson & Galloway. Those only are here described which obtained first-class certificates. In several instances the certificates granted in 1874 under less favourable circumstances were now confirmed. The plants were inspected by the Committee on June 9th, and again on July 16th. The following may be regarded as a selection of the best of the bedding Pansies, chosen from the point of view of showing compactness and dwarfness of habit, profuseness and continuity of bloom, and useful and effective colours rather than that of size and shape in the individual flowers—chosen, in fact, for those special features which give them their value as bedding plants.

1. **Alpha** (Dickson & Co.)—A very compact-growing, vigorous-habited, free-flowering variety. Flowers large, bluish-purple, with a reddish flush; the eye yellow, with a bilobed dark spot in front. Good and lasting.

2. **Bedford Yellow** (Dean).—A free-growing compact-habited sort. Flowers large, bright golden-yellow, with pencilled eye. Good and effective.

3. **Blue Bell** (Dean).—A very showy variety of compact, spreading, free-blooming habit. Flowers numerous, medium-sized, mauve purple, with a small yellow eye pencilled with dark lines. The individual flowers are delicate in shape, but the effect of the mass is good, and the plant is a continuous bloomer. Awarded a first-class certificate in 1874, which was now confirmed.

4. **Blue Perfection** (Westland).—Of compact free-blooming habit. Flowers medium-sized, of a deep reddish mauve, with yellow eye. A fine effective self-coloured variety. The variety sent in as Purple Perfection proved to be the same as this.

5. **Dr. Stuart** (Stuart).—Of dwarf compact habit. Flowers mauve purple, with small yellow eye surrounded by a narrow dark ring. A neat and pretty flower.

6. **Golden Gem** (Dickson & Co.)—A variety of dwarf-spreading habit, and a free bloomer. Flowers large, deep yellow, with deeper eye, over which occur dark pencillings. Good and lasting. Awarded a first-class certificate in 1874.

7. **Lilacina** (Dean).—A charming variety of dwarf compact spreading habit, free-growing, and very distinct. Flowers of moderate size, the upper petals of a reddish lilac, the lower ones bluish lilac, with small yellow eye. An exceedingly pretty and taking flower.

8. **Lothair** (Dean).—A novel variety, with a dwarf compact habit of growth. Flowers large, deep purple, with small yellow eye, and broadish bronzy spot just below it on the lower petal. A distinct and rich-looking flower, of lasting quality.

9. **Lily-white Tom Thumb** (Dean).—A very useful variety, of free, compact, spreading habit. Flowers white, with yellow eye and dark pencillings. The flowers are tolerably constant as to purity, but they occasionally blotch in hot weather. The first-class certificate awarded in 1874 was confirmed.

10. **Magpie, or La Pie** (Dean).—An old French variety, still useful because striking in appearance from the strongly contrasted colouring of its flowers. It is of vigorous but rather tall-growing habit, of a hardy constitution, and an abundant bloomer. Flowers blackish mulberry, with a large wedge-shaped spot of white at the tip of each petal; the spotting sometimes runs out, when for a time the flowers become self-coloured.

11. **Mulberry** (Dean).—A dwarf-growing variety of compact but spreading habit and free flowering. The flowers are well displayed, of a dark reddish plum purple, with very small yellow eye. The first-class certificate of 1874 was confirmed.

12. **Novelty** (Cocker & Son).—A showy variety, of free-growing habit, but growing rather tall. Flowers reddish or puce-purple, with yellow eye; showy. A pleasing variety among the self-coloured flowers.

13. **Peach Blossom** (Dickson & Co.)—An attractive variety of close habit, and a free bloomer. The flowers, which are of good form, are of a curious motley colour, a reddish or puce-lilac, paler at the tips. Its neutral tint was thought likely to be useful in grouping.

14. **Princess of Teck** (Dean).—A very free-growing variety, and a continuous bloomer. The flowers are large, of good form, and of a pale bluish-lilac. It is quite novel in colour, somewhat approaching that of Lilacina.

15. **Queen** (Dickson & Co.)—A variety of free, compact habit, an abundant bloomer, but rather later than some others. Flowers large, white, with yellow eye and dark pencilled lines. The first-class certificate awarded in 1874 was confirmed. It is not, however, a lasting sort, as it was quite out of bloom when inspected in July.

16. **Queen of Lilacs** (Dickson & Co.)—A variety of free, bold habit, forming close vigorous tufts. Flowers, reddish-lilac, paler at the edge, being freely produced; a soft neutral colour, and useful for grouping. It was considered to be novel and effective, and on these grounds received the certificate.

17. **Royal Blue** (Dean).—A deep purplish-blue, with a dark eye. A showy and attractive flower, of good quality, and lasting.

18. **Sovereign** (Dickson & Co.)—Of close-growing habit, dwarf, free, and prolific of blossoms. Flowers moderate in size, of a bright deep golden-yellow, with a pencilled eye. Very effective, and a good lasting variety.

19. **The Tory** (Dickson & Co.)—A variety of free and vigorous growth, blossoming abundantly and continuously. Flowers large, deep bluish-purple, with white eye and a bilobed mulberry spot in front of it. Good throughout the season. The first-class certificate awarded in 1874 was confirmed. Under the name of *Monarch* was grown a variety not distinguishable from this in the colour of its flowers.

20. **White Swan** (Dean).—A fine variety, of close-tufted habit. Flowers of moderate size, pure white, with pencilled eye, of good substance, and very clean and chaste-looking.

21. **Williams** (Stuart).—A free-blooming variety, raised from *Viola cornuta*, fertilised by True Blue, a dwarf *Viola* like Perfection. It is dwarf and spreading in habit, the individual flowers being small, cornuta-like, and of a light mauve colour. The plant is very effective from the great number of its flowers, which are produced in succession, till late in the summer. T. Moore.

New Plants of the New York Horticultural Association.—At the exhibition of plants Messrs. Parsons & Sons, of Flushing, L. I., showed a lilac-colored *Daphne Genkwa*, at a distance somewhat like a Persian Lilac, and a pure white *Magnolia*, named *Haliana*, both these shrubs being from Japan. Mr. Roehrs, florist, Jersey City, had a new *Begonia*, with flowers 2 in. across, of the most brilliant scarlet. This species, sent by Mr. Roelz from Peru, is yet unnamed, according to the "American Agriculturist." The Association decided to hold its first exhibition in June, not for prizes, but the plants to be voluntarily contributed by the members, and other well-wishers of the Association. This course is unusual at horticultural exhibitions, which are usually made up of articles in competition for prizes offered, but the members feel confident that they can make their first exhibition one of which the Society will not be ashamed, without any drain on their treasury for prizes.

Sale of Exhibition Plants.—Mrs. Cole & Sons, of Didsbury, having decided to relinquish the exhibition department of their business, the whole of their valuable specimen plants were sold the other day by auction. The first day's sale was held at Withington, and the following are some of the prices realised for greenhouse plants:—*Boronia pinnata*, £10 10s.; *Aphelexis macrantha rosea* (Chilman's variety), £21; *Acrophyllum venosum*, £7 7s.; *Cordylina indivisa*, £27 6s.; *Azalea Trochiliana*, £15 15s.; *A. Ivoryana*, £10 10s. 6d.; *A. magnifica*, £110s. 6d.; *A. Cedo nalis*, £13 2s. 6d. *A. Duc de Nassau*, £13 2s. 6d.; *A. Conqueror*, £10 10s.; *Erica Cavendishi*, £20 9s. 6d.; *E. Lindleyana*, £16 5s. 6d.; *E. tricolor Wilsoni*, £12 12s.; *E. aristata superba*, £9 9s.; *E. affinis*, £9 19s. 6d.; *E. Masoni major*, £12 1s. 6d.; *E. Turnbulli*, £8 8s.; *Camellia esima*, £7 17s. 6d. *Double White Camellia*, £20. Among the more important prices realised for stove plants were the following:—*Cocos Weddelliana*, £50; *Croton angustifolium*, £14 14s.; *Anthurium Scherzerianum*, £50. For other lots comparatively high prices were also realised.

"**Arbour Day.**"—The Legislature of Kansas at its late session, by concurrent resolution, requested the Executive to designate a day to be known as "Arbour Day," and to recommend a proper and general observance of the same throughout the State. Governor Osborn accordingly issued a proclamation, setting apart Saturday April 1, as such, and inviting all the good people of the State to devote that day, or a portion thereof, to the work of beautifying the country by the planting of trees and shrubbery, especially commending to the popular care the streets, highways, and public reservations of every character.

The number of shade trees in Paris is estimated at 90,000. We, however, think the number is much higher.

SOCIETIES AND EXHIBITIONS.

ROYAL BOTANIC SOCIETY,

APRIL 26TH.

AMONGST the many interesting plants exhibited on this occasion were well-bloomed collections of Clematises from Messrs. Jackman & Son, of Woking, of which some account will be found in another column. Some new forms of *Mignonette*, shown by Messrs. Carter & Co., were remarkable examples of good cultivation. Some of the larger plants were fully 6 ft. in height, and formed perfect cones 4 ft. or more through at the base, and literally masses of fresh green foliage and deliciously-scented flowers. A new Hybrid Perpetual Rose, sent from Cheshunt by Messrs. Paul & Son, promises to be a most desirable variety. Of this some account will be found below.

Botanical Certificates.—These were awarded to the following new plants:—

Hypolepis Bergiana (B. S. Williams, Holloway).—This graceful Fern has triangular tripartite fresh green fronds, the smaller divisions being borne on a densely hairy rachis. It well deserves culture as a decorative stove plant, being both distinct and elegant in habit.

Niphobolus Heteractis (B. S. Williams).—A robust creeping Fern, having broadly ornate simple fronds bright green in colour and downy beneath, each being borne on a downy rachis about half the length of the leaf. It resembles in habit the old *N. Lingua*, but the downy, almost silvery, under-surface of the fronds gives it a distinct appearance. It will form a useful addition to decorative Ferns, especially for culture in baskets or on rockwork.

Floricultural Certificates.—These were awarded to the following new florists' flowers:—

H. P. Rose Duke of Connaught (Paul & Sons, Cheshunt).—This beautiful new Rose has smooth finely-incurred velvety petals of the richest crimson, shading off to fiery scarlet towards the margins. Its foliage, too, is stout, and of a deep green colour, which sets off the flowers to excellent advantage. It is undoubtedly a variety of first-class merit, and one which will be invaluable as a dark variety for exhibition purposes.

Auricula Mrs. Purvis (C. Turner, Slough).—A variety belonging to the grey-edged class; it has clean paste, surrounded by a deep velvety purple-body colour, which feathers delicately into the cool greyish-green margin. Being nearly perfect both in colour and truss, it cannot fail to be a favourite.

Stove and Greenhouse Plants.—Among Messrs. Jackman's Clematises we noticed well bloomed plants of *Vesta*, of which we this week give a coloured plate. In addition to its delicate colour, it has a satin-like lustre, which adds greatly to its beauty. Associated with it were *C. Stella*, a kind similar in form to *Vesta*, but larger, and its colour is bluish lilac, with a purplish bar down the centre of each segment. The *Queen* and *Lady Londesborough* are two well-shaped varieties, of a soft lilac tint. *Sir Garnet Wolseley* is a distinct and most prolific kind, the young flowers being of a rich claret purple tint, which in the old flower changes to dark blue with a claret-coloured band down the centre of each petal; *Mr. S. C. Baker* is a paper white variety, with eight blunt sepals, each having a rosy stain down the centre. These Clematises, being distinct in character from any of the other plants with which they were associated attracted much attention. *Mr. Ward*, gardener to F. G. Wilkins, Esq., of Leyton, had good specimens of the Jessamine-like *Elychnospermum* and *Balfour's* crimson and white *Clerodendron*; and in the same group was likewise *Ward's* variety of *Anthurium Scherzerianum*, with eight enormous spathes, the largest of which measured nearly 5 in. in length and about 4 in. in width. *Mr. Ward* also furnished well-bloomed specimens of *Erica Cavendishi*, the best of all yellow-flowered Heaths; a strong plant of *Pescatore's* *Odonotoglossum*, with three branching spikes; a large and well-flowered example of *Eriostemon intermedium*, and another of *Lycaste Skinneri*, the latter unusually well furnished with flowers. In this collection were likewise two or three well-bloomed *Azaleas*. *Mr. Turner*, of Slough, had six well-grown *Azaleas*, the best of which were *Bijou* de Paris, white striped with rose, and so floriferous that scarcely a leaf was visible; *Madame A. Verschaffel*, rosy-salmon, shading off into white at the crisped edges, and spotted with crimson; *Charmar*, a glowing cerise variety, of good form and substance; *Comtesse de Flandres*, a large crisped flower of excellent form, the colour being bright rosy-lilac; and *Reine des Fleurs*, a crimson-spotted variety of a delicate salmon colour, shading off into white at the margins. Messrs. Cutbush & Sons had also an interesting group of smaller plants. In the amateurs' class for *Azaleas* *Mr. Ratty*, gardener to R. Thornton, Esq., The Hoo, Sydenham, showed six shield-shaped plants well bloomed, the two best being *Duc de Nassau*, bright crimson edged with lilac; and *General Todleben*, a semi-double variety, of a vivid vermilion-scarlet colour; *Mr. James*, gardener to W. F. Watson, Esq., Isleworth, also showed a choice group in this class. *Mr. Heins*, gardener to F. A. Philbrick, Esq., Avenue Road, St. John's Wood, contributed a collection of well-grown *Orchids*, among which were two strong plants of the bright rosy-lilac *Massdevilla Lindeni*, each bearing five flowers and buds; *M. ignea*, bearing three vivid orange-scarlet flowers; three well-bloomed *Vandas*, and a good plant of *Phalaenopsis grandiflora*, furnished with four fine flower spikes. The same collection also contained a fine plant of *Odonotoglossum Rozeii* album, with eight spikes and thirteen large pure white flowers; and a very good

plant of the purple-spotted type, bearing two spikes; likewise, the pearly-white *Cypripedium niveum*, and the lilac-purple *Dendrobium litaiflorum*, both in good condition. Messrs. Carter & Co. sent the best six plants of *Dielstra spectabilis*, and beautiful examples they were of this most useful of all hardy herbaceous plants. Mr. James showed an effective group of *Cinerarias*, consisting of dwarf bright distinct-looking kinds. Among them we remarked *Picta*, a well-formed pure white flower, tipped with magenta; *Her Majesty*, carmine, with a distinct white circle round the eye, large and effective; and a deep blue self named *Purple Gem*. Messrs. Carter and Co. sent, in addition to their fine examples of *Mignonette* already alluded to, specimens of their new *Colerus Duchess of Edinburgh*, in good condition, its colour being brighter than that of any other variety.

Roses.—Mr. Charles Turner was the only exhibitor of Roses in pots. Among his plants, which were both well grown and well bloomed, we noticed the bluish tea-scented *Souvenir d'un Ami*, which is lovely in the bud, the petals being excessively soft and shell-like; *Mont Blanc*, a delicate sulphur-tinted tea-scented variety, the buds of which remind one of those of *Niphetos*, but in this case they are much smaller; *Paul Verdier*, a full and shapely rose crimson variety, the older flowers shading into lilac; the bright, rosy-coloured *Edward Moran*, and the bluish *Mlle. Therese Levet* were also very attractive, as were likewise *Charles Lawson* and *Marquise de Castellane*, although scarcely at their best. A plant of the ever welcome *Alfred Colomb* bore two or three delicately cupped blooms; this is one of the most beautiful and fragrant Roses of its class. A choice and well-arranged collection of cut blooms came from Messrs. W. Paul & Sons, of Waltham Cross; among these were the new bluish Rose *Captain Christy*, also *Gloire de Dijon*, the ever welcome *Maréchal Niel*, *Bonnes Rosenschilb*, with exquisitely formed soft rosy lilac flowers, and *Madame Bérard*, a kind in the way of *Gloire de Dijon*, but smaller and of a richer colour. Here again the delicate *Souvenir d'un Ami* was in lovely condition, as were also the sulphur-tinted *Celine Forestier*, and the new crimson, purple, or magenta-tinted *Star of Waltham*. A rather smaller collection of cut blooms came from Mr. J. Walker, Thame, who sent two admirable stands of *Maréchal Niel*.

Hardy Flowers.—These were well represented. Mr. W. Elliott, gardener to Latimer Clark, Esq., Sydenham Hill, showed a very select group of fresh and healthy plants, among which we noted the slender rosy-flowered *Epidemium rubrum* and its white-blossomed ally, *E. niveum*; also a dense specimen of *Anemone nemorosa bracteata*, bearing fully a hundred pure white star-like flowers set amid delicate cut fresh green foliage. Associated with these were also *Caltha palustris* minor fl.-pl., one of the best of all the double-bloomed kinds; *Anemone nemorosa fl.-pl.*, or double *White Wood Anemone*; the large white-flowered *A. trifolia*, a kind with solitary stellate flowers of pearly-whiteness as large as a crown piece, and a specimen of *Primula ciliata intermedia*, bearing quite a dozen trusses of rich purple yellow-eyed flowers. Mr. Clark also furnished a very effective group of seedling *Polyanthus-Primroses*, one of the best of which was *Empress of India*, a kind with a good foliage and stout erect trusses of golden-yellow flowers, having a vivid orange margin around the eye. The plant of this kind staged bore seven trusses, and is so robust and effective that it will prove useful either for spring beds or for pot culture. A dark crimson yellow-eyed variety, in the way of *P. auriculiflora*, was also an effective kind, especially for pot culture. Mr. Roberts, gardener to W. Terry, Esq., Peterborough House, Fulham, also sent an excellent collection, in which were *White Wood Lily* (*Trillium grandiflorum*), bearing a dozen large flowers; *Triteila uniflora* conspicua, furnished with about 200 flowers; the dwarf *Gold-tuft* (*Alyssum saxatile*), and the large-flowered *Purple Aubrietia* (*A. purpurea grandiflora*), the group being completed by well-grown plants of *Spiraea japonica*, *Dielstra spectabilis*, *Solomon's Seal*, and the delicate white variety of the *Wood Hyacinth* (*Scilla nutans*). The last four plants are perhaps the best of all hardy herbaceous plants for forcing, and they are kinds which may be readily grown as out-door plants in every cottage garden. Mr. Roberts likewise contributed a smaller collection, in which we remarked the well-known *Trollius asiaticus*, and a very bright orange-scarlet-flowered variety of the *Poet's Narcissus*, known as *N. Poetaurum*; the *Virginian Lungwort* (*Pulmonaria virginica*), and the dwarf shrubby *Daphne Caudatum*. *Ariculas* were rather poorly represented, the best collection being that sent by Mr. Charles Turner of Slough. In this the following were conspicuous, viz., *Lord Clyde* (Lightbody), a rich maroon self, the paste being pure and distinct; *Col. Champey's* (Turner), one of the best of its class, and nearly always good alike, the body colour being rich amethyst-purple; *Mrs. Sturrock* (Martin), an effective reddish-purple self, well worth culture; *Topsy* (Kay), a rich purple self; and *Charles Perry* (Turner), a lovely purplish-blue flower of good form and excellent in habit. The two last-named varieties were much and deservedly admired.

Miscellaneous Plants.—Mr. B. S. Williams showed a valuable collection of new and rare plants, among which we observed healthy specimens of the so-called carnivorous plants, *Cephaelis follicularis*, *Dionaea muscipula* or *Venus' Flytrap*, and the *Darlingtonia californica*; in addition to which we noted the delicately-beautiful *Adiantum gracilimum*, and some choice Palms, Yuccas, and Azaleas. Messrs. Cutbush & Son, of Highgate, also sent an effective group of decorative plants, consisting of *Ericas*, Palms, Azaleas, and Conifers, and a box containing about a dozen delicately-striped blooms of *Camellia Lavinia Maggi*. Beautiful cut flowers of bedding *Pelargoniums* came from Messrs. W. Paul & Sons, of Waltham Cross. For pot culture and for ornamental purposes the best of the varieties shown in this collection are valuable, especially early in spring, when effective flowers are, as a rule, scarce. Mr. T.

Peatridge, of the Boston Park Road Nursery, Brentford, sent twenty varieties of *Bronze Zonal*, and *Gold and Silver Tricolor Pelargoniums*, all in excellent condition. Mr. W. Elliott furnished a group of about a dozen golden-variegated plants in good condition, one of the best being a compact-growing *Galium* named *G. Molingo variegatum*, a kind said to be useful for bedding. Associated with it were also a golden-leaved *Dead Nettle* (*Lamium purpureum* var.), and two or three forms of the common *Stoncrop* (*Sedum acre*).

For a list of the prizes awarded on this occasion we must refer our readers to our Advertisement columns.

LAW.

WILLIAM GOSS, a gardener, was summoned the other day by Mr. David Sim, a nurseryman at Shepherd's Bush, for leaving his service without notice, whereby he suffered a loss. The question in dispute was whether it was the custom of the trade to give a week's notice. Mr. John Reeves, a florist at Acton, said he employed gardeners at weekly wages. It was customary to give a week's notice. A witness was called who said it was the custom to employ jobbing gardeners, not by the week but by the time they worked. The defendant was sworn, and denied that he had entered into any agreement with the complainant, but said he was to be paid at the rate of 2s. a week. The complainant told him that he could not afford to pay him wet or dry. The complainant, recalled, said he told the defendant that he should require reasonable notice. Mr. Ingham was of opinion that there had been a hiring. The defendant had not given notice and must make reasonable compensation. He ordered the defendant to pay 23s. compensation and 10s. costs. The money was paid.

OBITUARY.

MR. GILES MUNBY, whose death took place on the 12th inst., at The Holt, Farnham, Surrey, was a good botanist and cultivator of rare plants. Having resided for many years as a colonist in Algeria, Mr. Munby possessed an extensive knowledge of the flora, and compiled a list of the plants of that country, drawn up in French, and a "Catalogue" in Latin, including 2964 species. He grew many rare plants of North Africa in his garden in Surrey. Occasionally we had the pleasure of receiving communications from him for *THE GARDEN*, and, quite recently, one on the White-hooped *Peltocot Narcissus*, and another on the *Wood Sorrels*.

We regret to announce the death, on the 14th ult., of Mr. Richard Healdy, of Stapleford House, near Cambridge. Mr. Healdy had attained the patriarchal age of eighty-one, and for nearly half a century his name had been a "household word" among growers of the *Aricula*, *Tulip*, *Carnation*, and *Picotée*. Of each of these flowers he possessed an unsurpassed collection, and in each he had originated new varieties, which will long perpetuate his work and name. Until prevented by increasing infirmity, Mr. Healdy annually assembled the connoisseurs of the *Tulip* world at Stapleford House during the blooming season, and none who have been privileged to take part in these gatherings will be likely to forget the magnificent sight which his grand collection afforded, or the hospitality and geniality of the host. Mr. Healdy was indeed the very type of a genial English gentleman, and by his death Floriculture loses another of those worthies of an earlier generation, who, by word or work, or both, did so much for that branch of gardening.

NOTES AND QUESTIONS—VARIOUS.

Primula ciliata purpurea.—I had this pretty *Primrose* sent to me under the name of *Aricula Madame Vaucher*. It resembles *Primula intermedia*, but its flowers are larger than those of that variety, and of a rich rosy-purple hue. It is a very showy variety.—D.

The Adam Fig.—We have grown this variety for some years, and find it to be a sure cropper, the first fruit seldom or ever dropping off. We can, therefore, always depend upon it. The fruit is large, and pale brown when ripe. It is a kind which should be in every collection.—A. H., *Thoresby*.

Normandy Pippins.—These are prepared by putting peeled Apples in a slow stove or oven, taking them out at intervals, and pressing them between the finger and thumb at the stalk and eye, while the fruit is also turned round, so that the pressure should not be unequal. Why should this operation not be equally well performed in England?—E.

Brook's Liquid Carbolic Soap v. Ants.—I destroyed the other day thousands of ants by means of this liquid. They appeared to be shifting their quarters, as all of them were carrying eggs. I put a very small tumbler-potful of the liquid to a gallon of water, and sprinkled them with it, killing them instantly; it mixes with the water at once without any trouble.—R. H. B.

Destruction of Messrs. Boyd's Hothouse Building Establishment by Fire.—Messrs. Boyd's establishment at Paisley was almost wholly destroyed the other evening by fire, the cause of which is at present unknown. It covered nearly 2 acres of ground, and upwards of 150 workmen are for the time thrown out of employment. It is insured for £4000, but it is thought that the damage done will considerably exceed that amount.

Lo! the winter is past, the rain is over and gone; the flowers appear on the earth; the time of the singing of birds is come, and the voice of the turtle is heard in our ears; the fig tree puts forth her green figs, and the vines with the tender Grape give a good smell.

No. 233.] SATURDAY, MAY 6, 1876. [Vol. IX.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

CROSSING AND RAISING FANCY PRIMROSES.

It was my intention to have deferred offering any hints on the improvement of our present races of Polyanthuses and Primroses until the whole of my last year's seedlings had bloomed, but the plants that have already flowered display such an unmistakable advance on those of the previous season as to warrant me in assuming that the experiments which I have made will prove to have been a great success; and as it is possible that others may feel inclined to adopt some of the plans which I have practised, I hasten to communicate them, so as to permit advantage being taken of the present season. During the winter of 1874, my attention was called to that interesting article written by Mr. Darwin, about a dozen years ago, on the sub-diccious character of Primroses; and I then learned that but for his patient researches we should at the present time be labouring under the gross error of condemning the pin-eyed section, a mistake which has effectually retarded the improvement of three of our most popular hardy plants; and we can even now scarcely say that this error is dispelled, as it is probable that neither the Royal Horticultural Society nor the judges of our horticultural exhibitions would award a certificate or prize to an otherwise perfect flower if it displayed that imaginary defect. Perceiving the great value of Mr. Darwin's discoveries, I gladly availed myself of them, using pin-eyed Polyanthuses and Primroses for the seed-bearers, on account of the ease with which pollen could be applied to them, and because they produce the finest seeds. The pollen was, as far as possible, obtained from Primroses. The object of crossing Polyanthuses with Primroses will be obvious, if we remember that the union of different species usually imparts additional vigour of constitution to the offspring with increase of size and improved form to the flower, besides introducing to the Primrose the endless variations in shades and markings common to the former. But to return to the advantages arising from the seeding of pin-eyed flowers, the first consideration is the facility with which a cross can be accomplished, for if the plant be potted and kept in a still atmosphere free from the influence of insects, no further preparation is required, while a perfect command is established over it. Secondly, if we desire to vary the aspect of our Primrose banks and dells, what is easier than to touch the pin-eyed division with the pollen of our best Primroses and Polyanthuses, to effect a magical change. Again, let us suppose that a florist wishes to supply his customers with better seed than can now be purchased, though he may not be able to afford the requisite time to fertilise his plants, how readily he may obtain superior seed by planting alternate rows of selected pin and thrum-eyed Primroses; or, if he desire to produce Hybrid and Giant Polyanthus seed, he need only substitute Polyanthuses in place of thrum-eyed Primroses. Further, if monstrosities be in favour, then the judicious, mingling of Primroses with inflated calices with hose-in-hose Garibaldi and Pantaloon Polyanthuses will give such a multitude of nondescripts as would baffle the calculations of a very active imagination. To obtain the best results from hybridising, registration is so essentially necessary that too much stress can scarcely be laid on its importance; this object may be accomplished by adopting an easy method that I have practised for many years with great satisfaction, and I can with confidence recommend it to others, for attention to this requirement prevents the necessity of sowing seed that does not quite meet with the approval of the hybridist. For example, this present season my register shows that I have made ninety-seven different crosses, to which number fifty more may be added; but before the seed is ripe a large number of pods will be destroyed, because they will have been superseded by better crosses of superior though similar style. To show how readily registration is accomplished, a page is given out of my book for the present season, the names of the plants having

been changed to those with which the public are familiar. Each cross is marked by attaching a distinguishing bit of silk or thread to the flower-stalk of the bloom that has been fertilised. White thread is represented by w T; grey, by G T; black, by B T; black silk, by B S; white, by W S; orange, by O S; gentian, by G T; red, by R S; &c., &c. A few leaves of a metallic paper memorandum-book are prepared by ruling and numbering them, as underneath. The first division receives the number that represents the name of the plant, then follows the name, the other spaces being reserved for the registry:—

		W. T.	G. T.	B. T.	O. S.	R. S.	B. S.
1	The Bride	7	7		5		4
2	Magenta Ring		4		7		8
3	Mauve Queen		7		8		4
4	Violacea						
5	Auriculiflora						
6	Paper White						
7	Altaiaca						

Thus No. 1 or The Bride has been crossed with No. 7 or Altaiaca, and is marked with white thread, &c. &c.

It would be premature with our present limited knowledge of the sporting properties of fancy Primroses to determine precisely what features are essential to constitute a standard flower, and, therefore, for the present considerable licence must be allowed until the peculiarities of colours and marking have been sufficiently studied to enable us to decide what is most pleasing to the eye. For the purpose of deciding this difficulty it may be well to invite opinion to the subject in order ultimately to adopt the happiest suggestions. By way of example, I propose offering my own present impressions, reserving to myself the right of modifying my views as future experience may dictate; but before doing so, I beg to explain that I shall not advocate a single property that has not been attained by myself, though never in entire combination. The conclusions that I have arrived at are that the size ought not to be less than that of half-a-crown, possessing a circular outline and flat surface, with great substance of petal, which latter should be six in number; the eye ought to be small, round, and of a lively colour, or if of a medium or large size then it should exhibit foliated markings of a distinctive colour; possibly a shading of white round the outer circle of the eye may occasionally prove advantageous. The colour of the flower if light should be delicate or bright, or if dark then the colour can scarcely be too intense. Outer margins and lacings represent two distinct and pleasing styles, and may be white or yellow, as they assimilate best with the colour of the flower. Carnation stripes and markings will probably, when better developed, produce fine effects. Finally, no Primrose should be tolerated that has not a scent equally sweet with that of the Violet or Tea Rose.—A. CLAPHAM, *Ramedale Bank, Scarborough.*

SPUR PRUNING AND GROUND VINERIES.

I AM a grower of Grapes in ground Vineries, and should like to have the question of spur pruning alluded to in THE GARDEN (see p. 404) more fully ventilated. In my Vinery, 28 ft. long, in four 7 ft. lengths, running north and south, on April 8, 1869, I planted a Black Hamburg Vine at the north end, according to the instructions in "Rivers's Miniature Fruit Garden." It was planted from a pot and cut down to about 3 ft., the buds being just breaking. It continued to grow vigorously, but during 1870-71 I only allowed three or four bunches to ripen each year, leaving about 3 ft. of new wood at the pruning in autumn. In 1872 I obtained from it fourteen bunches of beautiful Grapes, weighing 15½ lbs., the heaviest bunch being 1½ lbs. In 1873 I gathered 19½ lbs.; in 1874, 22½ lbs.; and in 1875, I obtained thirty-seven bunches weighing 39½ lbs. of beautiful Grapes, the Vine having now filled the length of the Vinery, viz. 28 ft., and the rod being of immense vigour. I certainly feared that I had over-cropped it, although the foliage was of a splendid dark green, healthy

character, as it always has been, and I looked with some anxiety to the breaking of the buds this spring, but they have broken splendidly; at every spur there were two or three shoots, but I removed all but the strongest, and every one of these promises to produce two bunches, some of them three. Of course, I never allow more than one bunch to a shoot, and I shorten each shoot to one leaf above the fruit. I have generally begun to cut fruit the third week in September, but its flavour is now fully developed about the middle of October. In the year 1870 I planted a Golden Hamburg at the south end of my vinery, and in 1873 I gathered 5 lbs. of Grapes from it; in 1874, 6½ lbs.; and in 1875, 12½ lbs.; all the fruit being of beautiful quality. Now the difference between these two Vines bears very much on the question of spur-pruning, for while the Black Hamburg seems of almost equal vigour, from the lowest shoot to the one at the end of the rod, the Golden Hamburg bears its fruit almost entirely on last year's wood, the two shoots at the extremity having two large bunches each, while those on the three-year-old wood show scarcely any signs of fruit; therefore, before cutting back the shoots, as I usually do, to four leaves, I want some of your readers to inform me if it would be better to run up a new cane, even if it were a weak one. My ground Vinery has been quite a source of pleasure to me, and I consider it a great success; but as I have hitherto performed all the pruning and the greater part of the thinning myself, I found the removing of the frames for this purpose a nuisance, and I therefore devised a plan for sliding the frames on angle-irons raised about 14 in. from the ground, and kept at their proper distances apart by iron rods, to which the Vines can be fastened when they require to be raised from the ground. Small brass castors fixed to the bottom of the frames enable me to slide them along either for ventilation or for pruning, and I find them most convenient. In 1874 I obtained two plants of Duke of Buccleuch from Mr. Thomson, and prepared for them as follows:—I removed the angle-iron from the east side of my Vinery, and replaced it with inverted L iron, and then fixed the angle to the east of that at a distance to receive another set of frames, thus making a double vinery, the bottom of which is laid with thick tiles that retain a great amount of sun-heat. At each end of the second division I planted the Dukes of Buccleuch in May, 1874; and last year I allowed two bunches to ripen on each Vine, 4 lbs. of beautiful Grapes being the result. Although they had not the advantage of artificial heat, some of the berries were very large in size. These two Vines made very fine canes, which were cut down to 3 ft. of that year's wood; and as I allowed 3 ft. of the wood made in 1874 to remain, they are just about 7 ft. long at this time. But here again I find the same thing occurring in the case of the Golden Hamburgs, *i.e.*, they are making most vigorous shoots; but the two shoots at the extreme end of each are not only much stronger than any on the previous year's wood, but they have two large bunches on each shoot, all the other shoots on the same wood being fruitful, while the wood of 1874 has scarcely a shoot which appears fruitful. Now, I should very much like to know if I ought to bring up a cane from the bottom of each cane as bearing wood for another year, or to continue the spur-pruning. E. W.

Worcester.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

The Early Beatrice Peach.—This is now ripe and in every way excellent while fruit of the Grosse Mignonne, Royal George, and other sorts in the same house and subjected to the same heat, will not be ripe for at least a month to come, although the fruit of the Early Beatrice is not of the largest size, the exceeding precocity of the variety renders it valuable for forcing.—T. FRANCIS RIVERS, *Bawbridgeworth*.

Rust in Grapes.—The Grapes this year in my first house have got a little rust on them; will any of your readers favour me with their opinion as to the cause of it? A cultivator upon whom I called one day told me that he had spilt his early house of Grapes by using sulphur on the pipes, which caused the berries to rust; but that cannot be the cause of the evil in my case, as I have not used sulphur once this year. In my opinion cold draughts are more likely to cause rust than sulphur.—G. H. G.

Hardiness of the Duchess of Oldenburg Apple.—Mr. Jordan, of Minnesota, states in the "Prairie Farmer" that he has 800 trees of this variety and has not lost one by the cold of the winter there, which is severe enough to destroy most other kinds. He thinks it as hardy as an Oak. It comes into fruit when about six years old, and is an annual free bearer.

NOTES OF THE WEEK.

—THERE were large numbers of Apples and Pears shown at the late exhibition at Brussels, and apparently well preserved—such kinds of Pears as have long been past in England. Mr. Jones, of Frogmore, sent a large collection of Apples in good firm condition; among them were samples of Cox's Orange Pippin, looking as well as they usually do in December.

—THE recent consideration by the Botanical Congress, held at Brussels, of the question of a complete catalogue of the plants introduced to European gardens ended in a resolve to bring London's "Encyclopædia" up to the present state of our knowledge. Such a work is much needed, and we wish it all success.

—THE annual exhibition of Rhododendrons and other American plants from the nurseries of Messrs. John Waterer & Sons, of Bagshot (which for upwards of twenty years formed such an attractive feature at the Royal Botanic Gardens, Regent's Park), will this year be held in the grounds of Manley Hall, Manchester.

—IN the "Belgique Horticole" for March is a coloured representation of the Fruiting Duckweed (*Nertera depressa*), showing how abundantly its brilliant orange-red fruit is strewn over its oval fleshy leaves that lie flat as a carpet on whatever supports them. It is a plant which has been frequently alluded to in our columns, and one which should find a place in every garden. It was introduced by MM. Schiede and Deppe, who discovered it in the temperate regions of Mexico; but it is a plant which, at certain altitudes, has a wide geographical distribution.

—A TREE-LIKE specimen of the bright and free-flowering *Malus floribunda* is now a dense cloud of flower in Van Houtte's nursery at Ghent. The most striking effect afforded by this valuable tree is before its bright buds are open, but it is scarcely less lovely when in full bloom. It is known to many in England as a bush or small tree, and to these some evidence as to what it is when matured may be useful. It seems to be as vigorous a grower as any of its family, and we, now having seen it in a fairly developed state, do not hesitate to name it as the handsomest hardy flowering tree introduced within the past twenty years. Young specimens of it are procurable in many of our nurseries.

—AMONG choice fruits now obtainable in Covent Garden Market are new hothouse Grapes of excellent quality, the varieties being Foster's White Seedling and Black Hamburg; also forced Strawberries and Melons from English market gardens, Peaches and Cherries from Belgium and France, together with excellent White Calville Apples, and a few samples of Easter Beurré Pears. Smooth Cayenne Pine-apples from St. Michael are also plentiful, and we notice that the finest fruits are now imported on plants in pots just as they are grown. The first cargo of Smooth Cayenne Pines sent to Liverpool in 1868 was imported in this way, and sold as well or even better than home-grown fruit. Among novel or little seen fruits may be classed the Loquat, or fruits of *Eriobotrya japonica*, which are like small oblong Apples, but of a golden yellow. Chinese Litchees and S. American Sapucaia Nuts are also obtainable, and add variety to the limited list of seasonable dessert fruits.

—We hear that an International Horticultural Exhibition is talked of for the year 1878. Such an exhibition, worthy done, could not fail to be beneficial to horticulture; but it seems to us that there are good reasons for deferring it to a more distant date. The great French Exhibition takes place in that year, and so do one or more great Continental shows, and it would not be wise to clash with these in the remotest way. English growers should, we think, have the fullest notice of such a project, and three clear years for preparation ought to be allowed. With such notice, we believe the next International Show in England would surpass by far all floral exhibitions ever seen. Nothing can be lost by allowing the fullest time to the growers and to those on whom the heavy responsibility of organising the show would fall. We have so many great shows, both national and international, now-a-days, that nobody can be very anxious for another, unless, indeed, it be a one that may be fully representative of the treasures of our gardens and the skill of our cultivators at the present day. With such timely notice many good cultivators would make special preparations from the beginning of objects worthy of the occasion, and not merely adapt existing, and perhaps often shown subjects, for the competition in question.

—THE fine collection of florists' Tulips formed at great cost by the late Dr. Plant, at Monkstown, near Dublin, is now offered for private disposal, as may be seen by reference to our advertisement columns.

THE INDOOR GARDEN.

THE PANAMA HAT PLANT.

(*CARLUDOVICA PALMATATA*.)

THE *Palmato* *Carludovica*, of which the annexed is a representation, is undoubtedly the most elegant species of the genus to which it belongs. During the last twenty years it has acquired vast importance as the source of the fibre used in the manufacture of the true Panama hat. A glance at fig. 1 will give an approximate idea of the beauty of the plant, which should always occupy a prominent position in all collections. The *Carludovica* was introduced into Europe about the year 1808. It is a native of Bolivia, Peru, New Granada, and Ecuador, and prefers damp sheltered positions in the deeply wooded valleys of that part of South America.

It is in general stemless, the leaf-stalks and flowers shooting directly from the root. The leaves, which are mounted on a solid triangular petiole, are palmate and folded like a fan. As they increase in size, they split into three or more divisions. The leaf disc varies in diameter from 16 in. to 30 in. and even more, the leaf-stalk being often 6 ft. or 7 ft. in length. When carefully cultivated, the leaf is of a brilliant green. The flowers, although they do not constitute the chief beauty of the plant, are nevertheless singular in their way. They are monocious, on the same spadix, the female flower being surrounded by four males. The ripened spadix is most remarkable, both as regards form and colour. Fig. 2 (see p. 427) is a good representation of this extraordinary-looking fruit, taken from a ripened spadix which was borne by one of the *Carludovicas* in the *Jardin des Plantes*, and which forms the only instance, as far as we ("Revue Horticole") know, of a spadix of this plant ripening in Europe. The spadix, on reaching

maturity, breaks up, exposing the inside of the fruit as well as the axis round which it is placed. These parts are of a most brilliant scarlet, which is rendered all the more intense by the strong contrast of the bright green surface of the spadix and of the leaves by which it is surrounded. Could the *Carludovica* be induced to fruit regularly in our hothouses, the breaking up of the spadix would add an additional beauty to that already possessed by this elegant plant. In Weddell's "Travels in North Bolivia," we find an interesting account of the manufacture of Panama hats from the leaves of this plant. The Bolivians give the *Carludovica palmata* the name of *Jipagapa*, a town in the Republic of Ecuador, which is the principal seat of the hat manufacture, "Panama," like "Mocha" in the case of coffee, and "Brussels" in that of carpets, being a misnomer. Before the leaf has begun to open—when, in fact, it resembles a closed fan, it is cut off close to the petiole, the base of which forms the centre

of the crown of the hat. It is then divided longitudinally into strips with the thumb nail, the thick part forming the mid-rib being rejected. The number of shreds into which it is divided of course depends on the fineness of the hat into which they are to be manufactured. The split leaf, which is of a greenish-white colour, is next dipped into boiling water, then into tepid water acidulated with Lemon juice, and lastly it is allowed to soak in cold water for some time, and afterwards dried in the sun. Each hat is, or ought to be, made of a single leaf. They vary in price according to fineness, from eightpence to as many pounds. The damping and drying operations cause the shreds to assume a curled or cylindrical form which much increases their strength without injuring their pliancy. Before plaiting, the coarser qualities are damped with water, but the finest sorts are left out in the morning dew, and worked on before sunrise. A hat of the finest quality, made out of a single leaf, will take several months to make it complete, and the plaiting will be so fine as hardly to be perceptible at a short distance. The *Carludovica palmata* is by no means difficult to cultivate, and it is one of the most hardy species of the genus. It grows well in the damp heat of an Orchid-house where the temperature does not fall below 60°. The heat ought to be maintained pretty constantly at this point, for if it be allowed to go much above it, the leaves show a tendency to become darker. The pots containing the young plants should be plunged in tan, without which the leaves will turn yellow and wither. In January or at the commencement of February, they should be repotted in coarsely broken turfy peat, mixed with a fifth part of soft light clayey earth, a mixture which seems to suit them admirably. When the plants are four or five years old, a number of buds begin to develop themselves round the root, which should be separated from the parent plants and placed in a warmed and closed

case, and kept from contact with the air until they have taken firm hold of the soil, after which they may be treated as described above. If the plants have received proper care, they will flower in four or five years. The Panama Hat Plant may also be propagated by means of seeds, which should be simply placed on a lump of turfy peat, which must be maintained constantly wet and covered with a bell-glass in a warm place. The seeds generally germinate in about six weeks or two months. As soon as the young plants are sufficiently developed, they are potted off and allowed to remain in heat until they are thoroughly established.

Like other kinds of Screw Pines, an Order to which this plant belongs, it requires a copious supply of moisture at the root all the year round, but more particularly when it is making its growth. Good specimens of this plant may be seen at Kew, and it is also not uncommon in other good gardens where it is grown for the sake of its elegant fresh green Palm-like foliage.

Fig. 1.—The Panama Hat Plant (*Carludovica palmata*).

CULTURE OF *ÆSCHYNANTHUSES*.

THESE are handsome free-flowering plants, possessing a very distinct habit of growth; they are mostly indigenous to the hot, damp, woody districts of Java, and consequently require a high temperature. Their flowers, which are scarlet and yellow or deep crimson, are produced freely from the axils of the leaves and extremities of the current season's shoots. In their native habitats they are epiphytal in character, growing on the trunks and branches of trees, to which their roots cling. In a cultivated state they are of moderate growth, and are especially well adapted for pots or wire baskets, suspended in the stove over paths and from the rafters; thus managed they are very effective, and supply a place for which comparatively few plants are suitable. Their blooms are produced in succession during the summer and autumn months, when they form an agreeable contrast to other plants. They flower freely in a small state, and consequently are suitable for either large or small houses.

To grow them well they require too much heat to succeed satisfactorily all the year round in an ordinary Fern-house; but, kept in the stove whilst making their growth and until the flowers begin to open, they may then be removed to a conservatory or Fernery; in the latter they produce a striking effect drooping over the green fronds of the Ferns. Half-ripened cuttings of all the kinds taken off in the spring root freely inserted in small pots in half sand and peat, and kept close in a propagating frame or under a bell-glass; they will succeed without bottom-heat, provided the temperature of the house is sufficient to promote growth. Cuttings may usually be obtained in proper condition about the beginning of April, and, if placed in a night temperature of 70°, will root in a month, when they may be gradually inured to the full air of the house, tilting the glasses a little more each day until they can be dispensed with altogether. Pinch out the points of the shoots at a few joints above the base, in order to lay the foundation for the future plant by inducing the formation of several shoots. As soon as the pots are filled with roots, remove the plants into others a couple of inches larger, using fibrous peat, to which add one-sixth of sand and crocks broken small, in equal parts; this will be found to suit the roots better than a closer material. Fill the pots to one-fourth their depth with drainage, as *Æschynanthuses* cannot endure stagnant moisture, at the same time they require during the growing season an abundant supply of water to the root, necessitating provision being made for its passing freely off. They should be placed on a front shelf, where they will receive a fair amount of light, but they should have a thin shade during the hottest part of the day. As solar heat increases, raise the temperature of the house to 75° at night, allowing it to get 10° higher when the sun is upon the glass, giving air when required, and syringing overhead when the house is closed. By midsummer again pinch out the points of the shoots, which will now begin to assume their natural drooping habit, to admit of which the plants should be set upon inverted pots. Continue to supply them with moisture, heat, and shade during the summer months, again pinching out the points of the shoots about the middle of August. Dispense with shading as the sun declines in power, and cease syringing, giving more air and less atmospheric moisture. Keep them through the winter in a temperature of 60° at night, and a little higher in the day time, giving as much water to the soil as will keep the roots a little moist; at the end of March shift them into pots two sizes larger than those they are in, using the soil in a little rougher state and adding crocks and sand as before, draining the pots in a similar manner. The shoots must not be stopped now, or the time of flowering will be delayed, treat them as regards heat, shade, and moisture as recommended in the preceding summer. By midsummer the early blooming sorts will show flower; the latter kinds, such as *Æ. splendens*, later on. When the blooms open, the plants may be kept in the stove, or removed, as already stated, to a somewhat cooler house for a few weeks, but they must never be submitted to a cold dry atmosphere. When they have ceased flowering replace them in the stove, and cut back the whole of the growths to within 10 in. of the base. If this be not done, they will get into a straggling condition, with their flowering shoots disposed irregularly, and destitute

of healthy young leaves near the base; if the shortening be deferred until spring, considerable time will be lost, and fewer blooming shoots will be formed. The cut-back shoots will break and make some growth before the end of the season, and, if in good healthy condition at the roots, a number of young growths will push up from the base. Keep them through the winter as during the previous dark months, and repot them in the spring, giving them a 2-in. shift; they may either be hung up by wires fastened round the pots below the rim and joined above the plants, or the pots may be plunged in wire baskets, and the space betwixt the pots and the sides of the baskets filled up with Moss, a way in which they look much the best; in this case broad shallow pots should be used. After potting treat them generally as in the preceding summer. This season, if all goes well, they will make many more shoots, and will bear a proportionate increase of flowers. They will also be benefited by manure water once or twice a week. After they have bloomed cut them well in as before; in the spring they may have a portion of the old soil removed, without disturbing the roots too much, replacing it with new material, and returning them to the same pots, if these be deemed large enough; if not, they may be put in others an inch or two larger. In this way they will last for years.

The following are sufficiently distinct to merit a place wherever plants in hanging baskets are desired, viz.:—*Æ. grandiflorus*, a species which comes from Khosea, and one which will bear a considerably lower temperature when at rest than the other kinds that have been introduced from Java; its tube-shaped flowers are produced in bunches, and are of a bright scarlet colour suffused with yellow. It blooms in August and September. *Æ. splendens* is a garden hybrid, produced betwixt *Æ. grandiflorus* and *Æ. speciosus*, and is the finest of the strong-growing kinds. Its flowers are produced in bunches of ten or a dozen, and are of the most intense scarlet; the segments being marked with blackish brown. It flowers in the summer. *Æ. Lobbianus* is a handsome sort, with scarlet flowers, produced in summer and autumn. It is a native of Java. *Æ. Boscbianus* is a distinct and pretty species, also introduced from Java. Its flowers are brilliant scarlet and yellow, and it keeps on blooming for a considerable portion of the summer.

Æschynanthuses are little troubled with insects such as thrips and red spider, as these can be easily kept down by the use of the syringe—their thick leathery leaves being easily cleansed by this means. Mealy bug and scale will sometimes affect them, but these may be kept in check by sponging and a free use of the syringe.

T. BAINES.

POTTING EPIPHYTAL ORCHIDS.

It is difficult to say what season of the year is best for this operation, the different quarters of the globe from which the plants come, being so unlike each other as regards climate. Even if we carefully study any section of the Orchid family from any given country, and imagine that we can tell the proper growing season for that particular section, although we may be right in the main, we shall find ourselves at fault with respect to certain varieties which, although coming from the same country, have peculiarities of their own which will not permit of their being treated in the same way as the others. Differences in elevation at which plants are found growing affect the treatment to which they should be subjected, those coming from a high elevation bearing much more cold than those from the low lands; it is therefore expedient that amateurs obtaining newly imported plants should ascertain, if possible, not only the country from which they come, but also the elevation at which they were found growing. Again, if we take a single variety, say for example *Oncidium Papilio*, or the different varieties of *Cattleya Mossia*, which are found growing over a large tract of country in South America, and even in some of the West India islands we shall find a difference in the time of growing and in the amount of heat which the plants require, inasmuch as they retain under cultivation the likes and dislikes acquired by them in their native habitats. A remarkable incident in proof of this occurred about five winters ago when two lots of *Cattleya Mossia*, collected in different localities, were placed side by side in the

same house. One lot was almost all killed by the cold, while the other, from a cooler quarter, was apparently uninjured. By far the greater number of Orchids, however, have been found to adapt themselves to our seasons—beginning growth in February, March, and April, sometimes working round to these months gradually, gaining a little each year until they at last come right, while in other cases, as in that of fresh importations arriving in this country in autumn, the young growths, which were about to start when the plants were gathered, are kept in abeyance Spring, therefore, is, upon the whole, the best time for the general potting of Orchids, as at that season the greater part of the plants are growing, or about to do so, and they are in an active condition, which renders them capable of making compensation for any injury which the roots may receive, and, as the plants make new growth and new roots in the spring, it is the best time to give them fresh material to root into; for, if the potting be done in autumn or winter, unless in exceptional cases, any injury done to the plants in shifting must remain until spring before it can be made good, and in the meantime the plants suffer. The material, also, is likely to become impaired before the plants are in a suitable condition to enable them to make use of it; Orchid growers must, however, be guided more by their own judgment than by any rules laid down as to the proper time for potting, for in this they are best assisted by certain indications given by the plants themselves; the best condition for potting being when they are starting into new growth, a circumstance which cannot be too strongly impressed upon the mind of the cultivator, for by always having this rule before him and acting upon it, he will be spared a great deal of doubt and inconvenience; he should examine his plants as often as possible, treating each one by itself, and carefully inspecting it in order to ascertain if it wants potting; if it be in a healthy condition, well rooted, and not in any way cramped, it will be better to work out as much of the old material as possible, and replace it with new; clean the plant, and leave it otherwise undisturbed, for many Orchids, if potted when that operation is unnecessary, are thrown out of flowering until they can re-establish themselves. It is not good practice to pot each plant every year, as many Orchids will remain three or four years in the same pots or baskets if carefully attended to; but on the other hand, in the case of a sickly plant having little or no root, putting it into a small pot or basket, and giving it a frequent change of material in which to grow, rarely fails to produce good results, for after two or three changes, the plant usually starts into growth and does well, particularly if some living Sphagnum Moss be mixed with the peat in which it is planted. The foregoing remarks apply equally to plants in baskets and

in pots. Let us now advert to a few of the leading varieties beginning with those which experience has taught us do best in Sphagnum Moss. With the stronger growing kinds, such as *Vanda tricolor*, *V. suavis*, (*Aerides odoratum*, *A. suavisimum*, *Angraecum sesquipedale*, and others of similar habit, we have no difficulty, inasmuch as they have tall stems, well furnished with air-roots, and do well in pots, the success in cultivating them depending more on the temperature and atmosphere of the house than on anything else. The medium-sized varieties, such as *Saccolabium guttatum*, *S. retusum*, *Vanda coerulescens*, *V. Cathcartii*, &c., although safer in baskets, may be grown in pots, but more care is required in their management. In crocking pots for them, it is well to fix a good sound log, or a 2-in. or 3-in. unglazed drain-pipe in the crocks, leaving the log one half in and the other half out of the pot; then place the plant against the log, keeping it several inches above the level of the rim of the pot; place some of the lower roots over the top of the crocks and fill in carefully between them with Sphagnum Moss, and some large pieces of charcoal, placing a layer of Sphagnum on the top; water sparingly for a time, and the plant will root over the log and among the pieces of charcoal, and be quite safe without giving much trouble; whereas, if potted in Sphagnum Moss alone, the utmost vigilance will be necessary to prevent it from becoming sodden. Dwarf-growing kinds, such as *Saccolabium curvifolium*, *S. ampullaceum*, *Vanda cristata*, *V. coerulescens*, and all the varieties of *Phalænopsis*, I would strongly recommend to be grown in baskets; they are so easily grown in that way, and so difficult to manage in pots, that none but experienced Orchid growers should attempt their culture in pots. The above-named varieties, and others of similar habit having large air-roots, have been found to succeed best in Sphagnum Moss and charcoal, but it is by no means impossible to grow them well in either peat or in a mixture of peat and Sphagnum Moss. Good fibry peat, without any other mixture than a few lumps of charcoal, is the best for the stronger-growing *Cattleyas*, *Laelias*, *Oncidiums*, *Brassias*, and *Epidendrums*, and these plants do well in pots, but some

Fruit of the Panama Hat Plant (see p. 425).

of the smaller growing kinds, such as *Oncidium bifolium*, *O. Phalænopsis*, *Cattleya superba*, *C. bulbosa*, *Laelia acuminata*, *L. præstans*, and indeed any of the varieties known to be delicate, had better be grown in baskets or on blocks, care being taken to give them a copious supply of water during the growing season. *Miltonias*, *Odontoglossums*, *Lycastes*, and most of the other epiphytal Orchids from South America, not previously mentioned, thrive best in a mixture of equal proportions of good fibry peat and living Sphagnum Moss; the latter, by growing with the plants in the proper season, helps to maintain a uniform amount of moisture which is beneficial to all

of the smaller growing kinds, such as *Oncidium bifolium*, *O. Phalænopsis*, *Cattleya superba*, *C. bulbosa*, *Laelia acuminata*, *L. præstans*, and indeed any of the varieties known to be delicate, had better be grown in baskets or on blocks, care being taken to give them a copious supply of water during the growing season. *Miltonias*, *Odontoglossums*, *Lycastes*, and most of the other epiphytal Orchids from South America, not previously mentioned, thrive best in a mixture of equal proportions of good fibry peat and living Sphagnum Moss; the latter, by growing with the plants in the proper season, helps to maintain a uniform amount of moisture which is beneficial to all

Orchids, and absolutely necessary in the case of the New Grenada *Odontoglossums*. Most of the *Dendrobiums*, particularly those of the crassinode (*D. Falconeri*), and the nigro-hirsutum (*D. formosum*) sections must be grown in baskets or in suspended pots, so that they may have plenty of air. In this way they are easier to keep in health, and surer to flower, than if they were placed on the stage. *Stanhopeas*, *Gongoras*, *Acinetas*, &c., which push their spikes downward, some of them through the bottom of the basket, should never be grown in pots, or the beauty of the plants will be lost. It will therefore be seen that the principal requisites for Orchid potting are clean, living Sphagnum Moss, good fibry peat without soil, and pure charcoal; years ago it was the custom to scald the Sphagnum Moss, in order to kill the insects that might be in it, but it is now generally admitted that the benefit derived by its being in a living state more than counterbalances any drawback arising from the presence of a few insects which may afterwards be caught if carefully looked for and destroyed. The peat, which should be rather dry, should be broken with the hand into lumps, and the finer portions sifted out and thrown aside. Charcoal being good for all Orchids, may be used at discretion. During these last few years it has become customary to mix silver sand with the peat, &c., used for potting, a practice probably based upon the fact that certain varieties are said to have been found growing on rocks. I have tried the plan, and have in no instance found it beneficial to epiphytal Orchids, and in many cases it has proved to be injurious, the sand having become incrustated on the tender points of the roots, distorting and otherwise injuring them. It will be found to be better to rely on the materials which I have recommended, and to avoid any admixture whatever of sand. Another important matter is to prepare the plants which it is intended to pot by withholding water from them for several days before the operation takes place; the drier the plant is the better, for the roots will be the more pliable and less liable to injury; but if the plant be far advanced in growth, water should not be withheld long enough to check it; after potting, it should be watered but sparingly for some time, as it is found that if it be kept moderately dry, the young roots rapidly push themselves out in all directions, apparently in search of moisture. Some are in the habit of using pegs, either of wood or of wire, to keep the top layer of peat, &c., on an Orchid-pot in its place; but the wooden pegs, by rotting, often injure the plant, and the wire ones always injure any roots that may happen to grow against them; besides, such appliances are altogether unnecessary, for if the material be used in suitable lumps, and in finishing off a plant the top layer be commenced close to the plant and worked outwards towards the rim of the pot, the pieces last added round the edge will effectually hold the others in their places. The upright pot-like basket (invented, I believe, by Mr. Dominy) will be found to be excellent for growing medium-sized East Indian Orchids in, as, thus circumstanced, they will have all the advantages of plants in baskets, and may be placed on the stages as if they were in pots; it is made of Teak, and so constructed that air can circulate freely under the plant and amongst the roots. Wire baskets should never be used for Orchids. *Odontoglossums* of the *O. Alexandræ* class do not object to having the base of one or two of the back bulbs slightly under the Moss; but *Cattleyas*, *Laëlias*, *Oncidiums*, and almost all other Orchids having pseudo-bulbs, should never have any portion covered by the material in which they are potted except the roots.

JAMES O'BRIEN.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Marie Louise Violet.—Those who have hitherto written upon the culture of Violets in THE GARDEN have omitted all mention of this exceedingly fine variety. I have grown it for these last two years, and it is considered to be greatly superior to other varieties cultivated here, among which are the Neapolitan, King, Brandyana, the Czar, and Victoria Regina. If a little covering be given, there will be no cause for complaint as to short stalks for bouquet purposes.—J. ALLAN, *Ashurst Park, Kent.*

Ixora regina.—This attractive variety produces dense trusses of violet-salmon-coloured flowers. It is of a dwarf, compact habit, and the flowers are of a deep and lovely shade of colour; the trusses are somewhat similar in shape to those of *I. coccinea*, but the plant is more compact than that variety.—B.

THE FLOWER GARDEN.

HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

Among the handsomest of hardy flowers now in blossom are the Irids, and among these some seedlings from *Iris suaveolens* or *I. obliensis* are strikingly beautiful. Their colours vary from pale yellow to purple, blue, and white; some are dwarf in habit, like *I. pumila*, others are nearly as vigorous as *I. germanica*. The dark velvet-like flowers of the common Snake's-head *Iris* (*I. tuberosa*) are likewise now opening, as are also those of *I. sibirica* and the great dark-speckled *I. susiana*, one of the largest and rarest of all Irises, and one of the most peculiar as regards colouring. Some seedling Globe-flowers in a large bed in Messrs. Ware's Nursery at Tottenham are also just coming into bloom, their colours varying from yellow to deep orange. Among the more distinct hardy species of Tulips, *T. Eichleri*, *T. retroflexa*, and the slender-petaled *T. cornuta* have come into bloom during the past week, and the rich orange-scarlet *T. Greigii* is still very showy. Both the rosy and white-flowered forms of *Dielytra spectabilis* are now in flower in the open border, with their near relations, the *Corydalis* and *Fumarias*. Among late-flowering Narcissi, we have noticed the *N. muticus*, of Gay, a singular-looking form of the Common Daffodil, from the Pyrenees, the cup of which is perfectly cylindrical, and nearly 2 in. in length, and the segments of the perianth are more spreading than those of the Common Daffodil. *N. intermedius* and its orange-cupped ally *N. intermedius bifrons* are also now fairly in bloom, as is likewise the Silver Jonquil (*N. tenuior*), the flowers of which are of a delicate lemon-yellow colour when they first expand, but which afterwards change nearly to white. *N. gracilis* is also flowering freely, and is one of the most fragrant of all Narcissi. Among Primroses may be mentioned *P. intermedia* and *P. viscosa* var. *grandiflora*, two kinds now in unusually beautiful condition. *P. nivalis*, a delicate white-flowered form, is also very pretty on the rockwork at Kew, associated with the miniature Scotch or Bird's-eye Primrose, *P. scotica*—the last with rich violet-purple flowers, each having a yellow rim round the eye. Two of the most effective of all Primulas now in bloom, however, are *P. cortusoides* and its variety *P. amena*, both in excellent condition, at the Hale Farm Nurseries, Tottenham. The dwarf kinds of Phloxes are now beginning to open their flowers on sunny banks. During the past week *P. procumbens*, a deep rosy-flowered kind; *P. divaricata*, a delicate blue sort; *P. setacea atropurpurea*, a dark-flowered form of the type; and some large tufts of the snowy-white *P. Nelsoni*, have all been in great beauty. *Saxifraga hypnoides* is now studded with silvery blossoms, as is also the double-blossomed variety of *S. granulosa*. *Veronica repens*, creeping over sloping banks and rockwork, is thickly covered with pearly-white flowers, somewhat resembling those of *Saxifraga Bursariana*, but smaller. The Silver Rod (*Asphodelus albus*) is likewise now opening its flowers on spikes a yard or more in height. *Cyclobothra cœrulea* is blooming freely at Tottenham, as are also the North American Cowslips (*Dodecatheon Meadia* and *D. integrifolia*), and a new species from California bearing large panicles of slender purple flowers. The double-blossomed form of *Cardamine pratensis* is just coming into bloom, as is likewise the still more chaste *Ranunculus aconitifolius* fl.-pl., the double white flowers of which are as large as a shilling, and the sub-shrubby glaucous-leaved *Othonna cheirifolia* is studded with golden-rayed flowers. One of the most conspicuous of all the species of *Ornithogalum* is *O. nutans*, which has greenish or greyish-white blossoms, not unlike those of a Yucca in shape, eight or ten being borne on a stout spike. All the forms of Snake's-head (*Fritillaria Meleagris*) are still attractive, and *F. pyrenaica* is now fairly in flower; here and there *Lychnis alpina* is forming bright rosy patches in London gardens, and is, perhaps, the smallest species in the genus; while tufts of *Bellidistrum Michelli* are also studded with large Daisy-like flowers. The Musk Hyacinth (*Muscari moschatum*) is now in fine condition, as are also several of the Forget-me-nots, including *Myosotis alpestris* and the delicate blue *M. dissitiflora*. The elegant-habited *Lilium tenuifolium* is showing

Alpine Forget-me-not (*Myosotis alpestris*).

Snowy Primrose (*Primula nivalis*).

Musk-scented Grape Hyacinth (*Muscari moschatum*).

Single Jonquil (*Narcissus Jonquilla*).

Great Spotted Iris (*Iris susiana*).

Sulphur Narcissus (*Narcissus intermedius*).

Dwarf Iris (*Iris pumila*).

Scotch Primrose (*Primula scotica*).

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

colour in sheltered positions, but as yet it can scarcely be said to be in bloom. The charming little Bird's-foot Violet (*Viola pedata*) is very pretty, and its variety, *V. bicolor*, in which the three lower segments are white and the upper ones dark purple, is even still more conspicuous.

SELECT VARIETIES OF DOUBLE DAISIES.

So various are the sorts of Double Daisy now in cultivation, that a charming floral parterre might be made by means of them alone, or one large bed devoted to them might be made to produce an exceedingly effective display. If such a bed were round in shape, it might be filled as follows:—The outer circle to consist of the white-flowered Variegated Daisy, next which should be an inner line of the red-flowered kind; then a centre six-pointed star, consisting of a mass of the large White Daisy in the middle, the angular points being filled with the Blood-red variety; the six intervening triangles abutting on to the outer ring might be filled two each with distinct pink or rose-coloured kinds; this arrangement would be at once simple and good. So far, Daisies are rather limited in colour, consisting exclusively of White and Red, either self or in combination; but these combinations produce, nevertheless, a great variety—much greater, indeed, than is usually supposed to exist among Daisies. Putting aside for the present the variegated kinds, I find four distinct white sorts, and singular enough, these go in couples, for two are a larger and a lesser quilled white, and the others are larger and smaller flat-petaled whites; the flat-petaled is the oldest form, and the finest is the Giant White, a really excellent kind, having large full flowers pure in colour, and borne on long stems. This kind is well known in our London markets. The Common White has smaller flowers, and these usually have defective centres that militate greatly against their beauty; the stems, also, are shorter and the foliage rounder than those of the other. I do not think that any one would care to grow the latter, if they had the Giant variety. Not less remarkable as regards size and excelling the Giant in the density of its petals is the White Globe, a superb Daisy, fine in form and robust in habit; this, however, is a quilled kind, and therefore quite distinct. It is most useful to gather from for various purposes, and its flowers would not be despised even in a bouquet. A lesser kind I have obtained under the name of Queen of Whites, but the title is far too pretentious; this is also a quilled form, but the flowers, though good, are not pure, and altogether the kind is not equal to White Globe. The pink and rose-tinted kinds are more numerous, and comprise both quilled and flat-petaled kinds, one of the best known of which, no doubt, is the old Hen and Chickens. This is a pretty pink-flowered kind, and for a short time is very effective, but directly the "chickens" are developed it becomes more curious than beautiful, and is therefore entirely unfitted for bedding purposes. The best of the flat-petaled pink kinds is a variety that has petals with a white base and pale inner surface, the backs being rosy pink. This, when well grown, produces handsome flowers, some of them as compact as those of a *Ranunculus*, and owing to this cause it has from one source received the title of *Ranunculoïdes*; it is also known as the Belgian Daisy, but I prefer the designation under which I got it from Bedfordshire, viz., that of Rosy Gem. Another kind, from the same county, bears the name of Pink Beauty; this is a close-quilled kind, but shows the eye too much; its colour is rosy pink. The finest of the quilled flowers is the true old Mottled Daisy, now known as Early Gem; it produces large dense flowers borne on stalks of medium length, and is useful for furnishing cut flowers. Its petals are not so closely quilled as in the case of some flowers, and being red on the outside and white within, a curiously mottled bloom is the result, pink being the prevailing hue. It is very early and robust. Closely allied to this is Pink Queen, a less robust variety, but one which flowers freely and early. Its blossoms resemble those of Early Gem, but are not so large, and the petals are more closely quilled. It would probably make a good plant for edgings. Reds have four distinct representatives, the palest of which is called the Gem; the next deepest colour is the London Market Red; deeper still is the Blood-red, or, as it is sometimes called, the Sweep;

and darkest of all, quite a blood crimson, is Bacchus, a variety that has a distinct creeping habit, and medium-sized flowers born on long foot-stalks. All the flowers in the red section are quilled; the size of the blooms depends materially upon the quality of the ground in which they are grown, for as a rule I find that Daisies prefer good rich soil to poor ground. For bedding purposes I should prefer the Gem and the Blood-red as presenting the best habits of growth. The old Crown-flowered Daisy is still largely cultivated by market growers, owing to the robust character of the plant and the great size of its flowers. It is not liked as a bedding plant, because the centre of the blooms is usually hard and green until the flowers are nearly developed, when the inner petals expand, and a fine tufted or crown flower is the result. This also is a quilled variety, the petals being red and white, and the flowers present a mottled appearance, varying in character on many plants, just in proportion as the quilling is more or less dense. The foliage is large, round, and woolly, and easily distinguished. There has recently been sent out six varieties, under the names of Albert Edward, Albert Victor, Masterpiece, and others, all evidently seedling reproductions of the old Crown Daisy. I have these now in flower; I also flowered them last year, and I must say they are no advance upon old kinds. A few words remain to be said about that very pretty and interesting section, the Variegated Daisies. First, and perhaps the most effective among these is the well-known red-flowered kind, called *Aucubefolia*, so named because of the resemblance which its foliage bears to that of the Variegated Aucuba; this is a sport from the dark-red green-leaved kind, but, as might be anticipated, the variegated form is the less robust of the two. It is, however, sufficiently vigorous to be easily grown, and during the winter, before its flowers appear, its foliage is most effective. From this has also sported a pink-flowered kind, but in all other respects a duplicate, sometimes sporting back again, and, singularly enough, always so when the leaves lose their variegation. Flower of Spring is said to be a kind raised from seed. Its flowers are of a French-white tint, but the foliage is robust and well-coloured, being more veined than blotched. And, lastly, *B. globosa variegata* is a genuine sport from the White Globe, its flowers being pure white, and the foliage much blotched with yellow. The variegated kinds lose colour in summer, but regain it in winter. The above enumeration comprises all the garden double Daisies that I possess, or have met with. Any further information respecting them from other growers will be most acceptable. A. D.

Columbines as Biennials.—I would suggest that all the Columbines, except the common one, should be looked upon as biennials rather than good persistent perennials. The seeds should be sown early in spring, and the young plants pricked out into pans or into an old garden frame as soon as they are fit to handle, removing them early in August to their permanent positions; select a cloudy day for the work, and give them a little artificial shading for a few days after the operation has been performed. Carry out the same process year after year, the old plants being discarded after flowering. Any attempt at dividing the old roots is usually attended with a very small amount of success.—J. C. NIVEN, *Botanic Garden, Hull*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Miniature Floating Islands.—The following is a notion respecting which any suggestion from your readers would be thankfully received. We have in the college garden a large open tank to catch rain-water from the orchard-house roof, and wanting to utilise this we have put in a strong raft rising and falling with the water. We propose placing on this a number of water plants in pans, and are beginning with the lovely Bog Bean; probably the Huntsman's Cup (*Sarracenia purpurea*) would thrive under this treatment.—G. F. WILSON, *Heatherbank, Weybridge*.

Scutellaria macrantha.—In the last issue of THE GARDEN I observe that a comparison is drawn between the value of the desirable hardy Skullicap and *S. Mociniensis*, to the advantage of the latter. I have not a word to say in its depreciation, but surely the writer has done scanty justice to the former species by comparing it with a stove, or, if you will, a greenhouse species. I cannot imagine that the two plants can ever fairly be brought into competition with each other, belonging, as they do, to distinct sections of the genus. The *S. macrantha* would be quite out of place in the stove, and certainly no one would dream of planting its Mexican congener in the open border.—W. T.

THE KITCHEN GARDEN.

MUSHROOM GROWING ON A BRICK WALL.

WHEN in Lord Lonsborough's garden at Norbiton recently we witnessed a singular phenomenon—several groups of well-grown Mushrooms growing from the face of a brick wall at about 5 ft. from the ground. The spawn was also visible spreading about in graceful wren webs. The wall was covered, and in a dry shed, had ordinary mushroom beds placed against the other side, and from the uppermost of these the spawn had spread through the wall and produced excellent Mushrooms from the dry face of the wall. The wall is not even an old one, as the whole of the structures in the garden are of

recent date. This seems one of the most interesting facts in connection with Mushroom growing, and not without its value from a cultural point of view. V.

TRUFFLES.

AN article in THE GARDEN (see p. 417) on Truffle-growing in France induces me to offer a few remarks on this interesting subject. This highly-prized Cryptogam is only found sparingly in some of the southern counties of England; but in all young Oak plantations growing on calcareous soils, there is little doubt but that it might be successfully cultivated. In 1843 I commenced here an experiment of trying to induce Truffles to grow in a young Oak plantation near the lake, by getting all the parings and over-ripe ones from the kitchen and planting them in it. The soil of this Oak plantation had originally come from the bed of the lake, and was full of the shells of small fresh-water molluscs, so that it was of a calcareous nature. Wherever the old Truffles were planted I took great care that the Oak leaves should not be disturbed in the autumn or winter, in order that they might form a shelter for the young Truffles when growing. The first indication of the success of my venture was the fact of ripe Truffles being found in the places where the old ones had been planted by the squirrels scenting them out and scratching them up to eat. I forwarded a fine specimen, weighing more than $\frac{1}{2}$ lb. after having a piece cut off the top by the scythe of a mower, to the late Prof. Lindley, who pronounced it to be a veritable ripe Truffle. This plantation was afterwards protected and well attended to, and sometimes as many as from 2 lbs. to 3 lbs. of Truffles were dug up at a time when wanted for the kitchen. In digging for them there was, however, a great loss, for many of the small unripe tubers were destroyed by the spade from not having Truffle dogs to scent out those only that were ripe. Afterwards, from alterations in the grounds, this Truffle-producing plantation was destroyed, and there was an end of the crop, for the ground they grew on was raised 4 ft. higher. Where young Oak plantations are growing on calcareous soils, there is therefore little doubt but that the artificial cultivation of Truffles may be successfully tried in this country. Our climate may not be so favourable as that of France, but there is no danger of our severest winters injuring the young Truffles growing beneath Oaks or other trees, if the leaves be allowed to form a shelter for them, and no digging or disturbing the soil in hunting for them must be attempted after November. WILLIAM TILLEY.

Welbeck.

Conover's Colossal Asparagus.—Like Mr. Grieve (see p. 418) I find this variety far surpasses the ordinary kind during its earliest stages of growth; several beds planted with one-year-old plants of it last year are now sending up the finest growths I ever saw from plants only two years old; but of course, if they do not maintain this superiority for a number of years, their value will be materially diminished. Such large quantities of Asparagus are, however, grown for forcing purposes only that it is a great advantage

to grow a variety that will attain sufficient strength for producing good heads at two years of age, thereby saving one year's growth, the old variety requiring three years to be fit for the purpose.—JAMES GROOM, *Henham*.

NEW POTATOES IN SUCCESSION.

In order to meet the demand which I have for new Potatoes I plant at four different times. On the south side of our forcing-ground is a dwarf wall 120 ft. long; I put up a corresponding fence 4 ft. high, leaving a space 10 ft. broad between them. As soon as the leaves fall in autumn I get a great quantity raked up in the woods and fill this space cream-fall, treading them down well, and making allowance for their subsidence by building them up to 5 ft. high. On this I place some three-light boxes, and into these I put a foot of rather light soil. The Potatoes are planted immediately, and by care in keeping the lights well covered up new Potatoes are obtained by the second week in March. As fast as they are dug French Beans (Osborn's Forcing I like best) are planted; these afford us a capital supply during part of May and June, after which comes a crop of Vegetable Marrows. In November I get in my second batch of Potatoes, using a brick pit with good lights; no bottom-heat is used, but a good depth of soil is allowed, and the tubers are planted 8 in. deep. On the top are planted Lettuces, which were sown the third week in August; these are very useful for salads during March and part of April. The Potatoes in this pit afford a capital crop in April and May, after which the space is planted with, or rather is occupied by, Tomatoes in pots plunged, and these ripen perfectly. My third lot is planted in a similar manner about Christmas; and, after planting, Endive is put in, to be used in inclement weather. These Potatoes are dug in May, when the pit is filled with Basil, Marjoram, and other tender herbs. The fourth crop I am not able to plant till the 1st of February, but as soon as planting is finished a crop of Radishes is sown, and these are off before the Potatoes very materially interfere with them. This lot comes in in June. As soon as this crop is dug I have some old whole sets ready to plant, and after the soil has had a thorough watering of liquid manure I plant again and put on the lights, placing a brick under each corner of the light, which insures a thorough circulation of air. This crop must never have a drop of water after planting nor have the lights taken off. There is no fear of disease (says Mr. Rust, in the "Florist,") if this be attended to. When winter comes the lights are closed down and the crop is left undisturbed till Christmas, when they find their way to the table as new Potatoes. I must mention that nearly half my lights are covered with sheeting at 8jd. per yard, and two yards wide; this, when stretched tight and well oiled, answers capitally as a protecting material. I may add that the only Potato I grow is Veitch's Improved Ashleaf Kidney.

Vermont Beauty Potato.—This has proved here to be a most excellent late-keeping variety; to-day I have had a dish of it cooked and I have never eaten a better Potato. I mentioned some time ago that this is one of the best of the American kinds, aye, and of English sorts, too. It is also a handsome Potato; that coarseness both in haulm and root, so general in the American Potatoes, is quite wanting in Vermont Beauty. Its comparative freedom from disease, its short haulm, heavy crop, and early ripening and late keeping properties all contribute to make it one of our best garden Potatoes. It has the clean smooth surface of the best of English-raised Potatoes, and in many other respects leaves them a long way behind. Snowflake kept along with Vermont Beauty is not nearly so good.—J. TAYLOR, *Hardwick Grange, Shrewsbury*.

Fish Net Protections for Fruits and Vegetables.—I find that wall fruit trees, protected by means of double fish nets supplemented by light evergreen branches, have set abundant crops of fruit. I also find light coverings of this kind to be of considerable benefit to the earliest crops of vegetables, such as Carrots, Radishes, Turnips, Lettuces, &c.; such coverings break the force of the wind, which is far more trying to tender early vegetable crops than the amount of frost that we generally experience during the spring months. They must be supported on a temporary framework, at least 1 ft. above the plants covered; and during severe weather the amount of protection is easily increased.—J. GROOM, *Henham*.

Bitter Cucumbers.—I planted some Telegraph Cucumbers in a hot-pit, the bed of which was prepared in the usual way, and warmed with hot water. The shoots and leaves look healthy and strong and the Cucumbers are numerous, but so intensely bitter that it is impossible to eat them. The plants are trained under the fruit. Can any one tell me the probable cause of the bitterness of the fruit?—G. G.

PLATE XIX.

THE SALVIAS, OR SAGES.

(WITH A COLOURED FIGURE OF SALVIA FARINACEA.)

The Sages constitute one of the most natural and easily recognised genera in the vegetable kingdom, and yet they are exceedingly numerous, and diverse in duration, in the size and shape of the leaves, and in the colouring of the flowers. By one character alone any species of Sage may be distinguished from the species of any other genus of plants with two-lipped flowers. This is the singular structure of the stamens, of which there are only two in each flower. The filaments are branched, and the anther-cells are borne on separate branches. But I may make it plainer by quoting Mr. Bentham, who is the principal authority for this family of plants. "Stamens really two, although easily mistaken for four, for the anthers have a long slender connective, having the appearance of a filament, fastened by the centre to the very short real filament, and bearing at one end a perfect anther-cell under the upper lip of the corolla, and at the other end a small cell almost always empty, and usually much deformed." So much for the botanical character of the Sages, which, as may be gathered from the foregoing, are more easily recognised than almost any of the numerous genera of the family to which they belong. But it is not so with the species, for they number some five hundred, and are only separated into sections by floral characters less readily understood. These sectional characters are given below as a guide to the determination of a species, though in order not to scare away those readers who are not versed in botanical technicalities, but who may love flowers better than the most accomplished botanist, it has been thought desirable not to give full botanical descriptions of the species. The chief characters by which they differ from their allies are mentioned, followed by their general appearance, duration, height, colour of flowers, native country, and other interesting particulars. The history of the cultivation of Sages dates back to a remote period; several of the European species were esteemed for their actual or supposed medicinal properties. The Common Sage (*S. officinalis*) does not appear to have been used for seasoning at an early date; not even so far back as Gerarde's time, or he would most likely have mentioned the fact, but it was cultivated in gardens for its healing virtues. Miller describes a number of species, and several are figured in Dillenius's "Hortus Elthamensis." Sweet, in his "Hortus Britannicus" (1830), enumerates 141 species as being, or having been, in cultivation; and Loudon, a few years later, catalogues 124. Probably not one-half of these are now to be found in British gardens, and certainly not more than one-tenth of them are commonly grown, owing to the wide-spread mania for "bedding-plants." Of course, every one has a right to please himself or herself as far as possible; and if a person choose to have his flower-beds and borders empty nine months out of the twelve, there is only the law of good taste, which nobody is bound to heed, to prevent him. What may be in place, or at all events tolerated, in a portion of a large garden, is wholly unsuitable and unsatisfactory in a small one. But, without intending indiscriminate condemnation of any particular style of flower-gardening, or any particular class of plants, a word may be said in favour of those beautiful, and at the same time pleasant, homely, and natural, herbaceous plants (some of the Sages among the number) that in days gone by were more commonly seen than they are at the present time. Even the cottager, with his rod of flower garden, must imitate his wealthier neighbour, and plant Pelargoniums, which are certainly very beautiful plants, though not hardy. But the worst of it is, the charming old occupants of the cottage garden have been rooted up to make room for their more fashionable rivals, and a long time will doubtless elapse before we shall see the like again. Fortunately there are indications of a gradual change in this respect, and we may hope to see hundreds of different kinds of plants tastefully arranged, where we now see thousands of the same variety or a few varieties crowded together. There is scarcely any limit to the number of hardy species from which we may choose without troubling ourselves with those of too delicate a constitution to bear our climate if left to themselves. This is

abundantly proved by the genus now under consideration, and many others already reviewed in THE GARDEN. Salvias are found in almost all sub-tropical and temperate countries, but they find their greatest concentration in certain regions of the northern hemisphere, notably in the mountains of tropical America, and in the countries bordering the Mediterranean Sea. Two species are found in Britain, though one, *S. pratensis*, is exceedingly rare, and the other, *S. Verbenaca*, is very rare in Scotland. One species, the very widely-diffused Asiatic *S. plebeia*, is found in Australia. A considerable number of shrubby species occur in South Africa; a few, not very showy ones, extend to China and Japan; and there are several in the mountains of North India. The best hardy ones are from the Mediterranean region, and the showiest from the mountains of tropical America, especially Mexico. Few, if any, of the Mexican species are really hardy, but many of them are amongst the best ornaments of the conservatory and greenhouse during the autumn and winter months, and others are exceedingly effective in our beds and borders during the summer. In making a selection, several species which have been in cultivation are omitted, and a certain number of others not yet in cultivation have been added in a second list. Doubtless many of those included in the first part are no longer to be found in our gardens. Amongst perfectly hardy perennial species, or those requiring only a little care in the selection of a suitable soil and situation, the following may be named:—*S. Candelabrum*, violet-purple and white; *interrupta*, blue and white; *scabiosifolia*, white; *pratensis*, white, blue, and scarlet varieties; *dichroa*, blue and white; and *carduacea*, lilac-purple. The last is probably a biennial. Of greenhouse species we mention *S. farinacea*, leucantha, violet and white; *splendens*, scarlet; *iantha*, dark violet; *fulgens*, scarlet; *Grahami*, crimson; *Heerii*, scarlet; *elegans*, crimson; *albo-cœrulea*, white and blue; *patens*, blue; *tricolor*, white, violet, and vermilion; and *porphyrantha*, crimson. To enumerate all the ornamental species of *Salvia* would be to include at least 400 out of the 500 known, for almost every species possesses some peculiar grace or charm of its own, and many very fine species remain to be introduced. *S. longiflora*, for example, described below, surpasses, judging from dried specimens, anything in cultivation. Indeed, of the 200 to 300 American species, nearly all are not merely pretty but showy plants. Respecting the culture and propagation of Sages, little need be said, for few of them require special treatment. The herbaceous perennials may be rapidly propagated by division or from seed, and the half-shrubby species are as easily propagated from cuttings of the young soft shoots in heat.

The following is a selection of species which are, or have been, in cultivation:—

I.—Eusphace.

Calyx campanulate; upper lip three-toothed or nearly entire, lower lip bifid; all the lobes sharp-pointed, not increasing in size after the fall of the corolla; tube of the corolla broad, furnished with a hairy ring inside; upper lip erect, lateral lobes of the lower lip spreading or reflexed. Herbs or under-shrubs, natives of the Mediterranean region and Central Asia.

1. **Candelabrum Sage** (*Salvia Candelabrum*, Bot. Mag., 5017. —A half-shrubby species with leaves resembling those of the common Sage. It differs from all the others noted here in its regularly three-branched paniculate inflorescence, which suggested the specific name. The flowers are large and beautifully variegated with purple and white, the broad lower lip being almost wholly of a rich violet-purple. The style projects considerably beyond the shorter concave notched upper lip. This magnificent species is a native of the mountains of the South of Spain, at an elevation of 2500 ft. to 3000 ft., and is said to be quite hardy in this country. Mr. W. Thompson, of Ipswich, imported it about 1856.

2. **Irregular-leaved Sage** (*S. interrupta*, Bot. Mag., 5860. —A tall hardy herbaceous species, with a woolly, almost woody, stem; large irregularly pinnately-lobed leaves, 6 in. or more in length, and showy blue and white flowers. This is a very free-flowering ornamental species. It was in cultivation at Cambridge as long ago as 1798, and was re-introduced by Mr. Maw from Tangiers, in 1869. The tube of the corolla is short and inflated, and tinged with purple; the upper lip is short and notched in the centre, and the lower one has a very broad terminal notched lobe.

3. **Dandelion Sage** (*S. taraxacifolia*, Bot. Mag., 5991.—A very showy plant, with leaves resembling those of the Dandelion, and erect

spikes of large flowers in numerous clusters or whorls of six to ten each. Strong plants attain a height of 18 in., with flower-spikes 6 to 8 in. long, bearing six to eight whorls of purple, yellow, and white flowers. The corolla has a short broad tube and large gaping lips, the lower one, larger than the upper arched and concave one, is furnished with two large yellow spots and dotted with purple. A native of the Greater Atlas, collected by Dr. Hooker and Mr. Maw in 1871. It grows on rocks and shingle, and requires protection even on a rockery in this country.

4. Scabious Sage (*S. scabiosifolia*), Bot. Mag., 5209.—A most distinct species, the leaves, as the name indicates, being divided into narrow segments. The large white flowers are borne in distant whorls. The tube of the widely gaping corolla is short, and the central lobe of the long lower lip is much larger than the lateral ones; the outside of the upper arched lip is tinged with red and clothed with long hairs, and the lower lip is more or less spotted with red on the upper surface. One of the best of the perfectly hardy species. It is a native of Armenia and Tauria, and was introduced into this country in 1798. There is a poor figure of the same species in the Bot. Mag., 1429, under the name of *S. Hablitziana*.

II.—Hymenophace.

General characters of the preceding section, differing mainly in the lobes of the calyx enlarging and becoming membranous with conspicuous veins after the fall of the corolla. Herbs or shrubs inhabiting the Canary Islands, the countries bordering the Mediterranean, and South Africa.

5. Tawny-flowered Sage (*S. aurea*), Bot. Mag., 182.—A shrubby species with small entire leaves of variable shape, and large, yellow, ultimately tawny flowers. A native of South Africa, and more curious than beautiful in the tawny or rust colour of its flowers. It was cultivated by Philip Miller in 1731.

6. Canary Sage (*S. canariensis*) Trev Pl. Rar., ii., 19.—A shrubby species sometimes attaining a height of 5 ft. or 6 ft., clothed with a dense white tomentum. Leaves hastately-triangular, stalked; those on the flower-spike lanceolate and coloured. Flowers purple, in large branching panicles. This is a very pretty species, but it is rarely seen in cultivation. A native of the Canaries, introduced in 1698. The calyx enlarges, and becomes membranous in fruit.

III.—Drymosphace.

Calyx tubular or campanulate, with very short lobes; corolla-tube furnished with a ring of hairs inside; upper lip concave, or falcately-compressed, connective, as in the preceding. Herbs with green, usually clammy stems, and large hastate-cordate leaves, and yellow, rarely blue flowers. Natives of Europe and Asia.

7. Forskohl's Sage (*S. Forskohlii*), Bot. Mag., 988.—An herbaceous species, about 18 in. high, more or less clothed with a clammy pubescence. Leaves large ovate, coarsely-toothed, lobed at the base, lower ones stalked, upper ones sessile. Flowers violet-blue, in distant whorls of two to six on a branched inflorescence. A hardy species, native of South-eastern Europe and Asia Minor.

IV.—Horminum.

Calyx not enlarging after the fall of the corolla; corolla-tube destitute of a ring of hairs inside; connective bent downwards behind, abruptly flattened, and callous at the end. Herbs inhabiting the Mediterranean region.

8. Crested Sage (*S. Horminum*).—An annual species, of dwarf habit, with small oval-oblong leaves and rather small inconspicuous flowers, but the flower-spikes are terminated by tufts or crests of white, rose, or blue bracts. A very distinct and pretty plant from the South of Europe and Asia Minor.

V.—Æthiopsis.

Upper lip of the calyx three-toothed, the intermediate tooth very small; tube of the corolla enlarged under the throat, without a ring of hairs inside; upper lip falcate and compressed; connective deflexed behind and abruptly flattened, callous, and united at the tips. Herbs inhabiting the Mediterranean region and the mountains of Central Asia. The leaves and stems of most of the species clothed with a white wool.

9. Syrian Sage (*S. indica*), Bot. Mag., 395.—A large-leaved herbaceous species, with large flowers in distant bractless whorls of about five or six. The tube of the corolla scarcely exceeds the calyx, whilst the upper arched and concave violet-purple lip is nearly an inch long, and the curved projecting style almost touches the lower lip, which is curiously marked with yellow and dark purple. A hardy plant, cultivated by Miller in 1731; native of the mountains of Syria, but probably not of India.

10. Sims's Sage (*S. Simsiana*), Bot. Reg., 1003; *S. bracteata*, Bot. Mag., 2320.—A very distinct biennial species in the pair of large long-pointed pink-tinged bracts under each whorl of pale blue and white flowers. It is a tall branching herbaceous perennial, with large ovate wrinkled leaves, the lower ones stalked, the upper sessile, and gradually passing into the bracts. The very long concave upper lip recalls the long curved neck of the graffe. A native of Russia, introduced in 1820. Mr. Bentham refers this to *S. Sclarea* (Clary), of which it may be regarded as a superior variety.

11. Bristly Sage (*S. asperata*), Bot. Mag., 4884.—A remarkable plant of the *S. Sclarea* type, growing about 2 ft. high. It is clothed with glandular hairs, and the calyx is quite rough with bristles. The leaves are ovate-cordate in outline, irregularly toothed, and borne on long stalks, the blade being about 6 in. in length. The flowers, though large, are less showy than in many others, being of a greenish-white. A native of Cashmere; first cultivated in this country by Mr. Isaac Anderson, of Edinburgh, about 1855.

12. Silvery Sage (*S. argentea*), Fl. Cab., 112.—A tall-growing herbaceous species, with large wrinkled irregularly toothed-root leaves, 9 in. or more in length, and a branched inflorescence. The white or purple-tinged flowers are arranged in whorls of six to ten, each whorl subtended by large cordate concave sharp-pointed bracts. In its young state the whole plant is clothed with a close white tomentum. It is described as a perfectly hardy biennial inhabiting the Mediterranean region, but it appears to be strictly perennial in our gardens. Introduced in 1768.

VI.—Plethiosphace.

Calyx ovate, upper lip concave, two-furrowed, with three very short teeth; lower lip with two sharp-pointed teeth. Tube of the corolla enlarged below the throat, destitute of a ring of hairs inside. Other characters as in the last section. Herbs inhabiting Europe, Africa, and North Asia, usually with irregularly-toothed leaves.

13. Austrian Sage (*S. austriaca*), Bot. Reg., 1019.—An herbaceous species with naked stems, large, radical, coarsely-toothed and lobed leaves and yellow flowers in bracteate spikes. In colour and shape the corolla resembles that of our native *Galeobdolon luteum*, except that the terminal lobe of the lower lip is connected with the others by a very narrow isthmus, and the stamens are exerted. A hardy species, native of Austria and Hungary; introduced in 1776. It continues flowering for a long period, and is one of the best of the hardy kinds.

14. Meadow Sage (*S. pratensis*).—Among hardy Sages there are few that surpass this species, which is believed to be truly indigenous in Kent and Oxfordshire. It forms a very ornamental border perennial growing about 2 ft. to 3 ft. high, and producing a profusion of large blue, white, or scarlet flowers. The style projects considerably beyond the arched concave upper lip. This must not be confounded with the much commoner small-flowered *S. Verbenaca*. In Kew Herbarium there is a specimen of a variety with scarlet flowers.

15. Two-coloured Sage (*S. dichroa*), Bot. Mag., 6004.—This^{is} is certainly one of the finest of the Old World species. It is a nearly ally to *S. bicolor* (Bot. Mag. 1774), but a much more showy plant, resembling, as Dr. Hooker observes, *Collinsia verna* in the colouring of its flowers. A glandular hairy plant with stout stems, 2 ft. to 3 ft. high, ovate oblong leaves, the lower ones stalked, and long spikes of large blue, purple, and white flowers. The tube of the corolla is short and wide, and of a reddish purple, and the large lips are nearly equal in size, the upper one and the lateral lobes of the lower of a deep blue, and the centre lobe of the latter is pure white. A hardy species, native of the Greater Atlas; collected by Mr. Maw in 1871.

VII.—Calosphace.

Calyx ovate, tubular or campanulate; upper lip entire or shortly three-toothed; tube of the corolla without any ring of hairs on the inside, but sometimes furnished with two teeth near the base; upper lip straight concave, entire or slightly notched. To this section a large proportion of the most ornamental species belong. They differ widely in habit and inflorescence, but are not easily arranged in subdivisions. Natives of America and the West Indies.

16. Narrow-leaved Sage (*S. angustifolia*), Sweet's Fl. Gard., second series, 219.—A slender, herbaceous plant, 2 ft. to 3 ft. high, with long, very narrow, distantly toothed, sessile leaves, and blue *Lobelia*-like flowers. In this species the upper lip is very small, and the lower about three-quarters of an inch broad. A Mexican species, introduced into Europe in 1795.

17. Mealy Sage (*S. farinacea*).—The accompanying portrait of this species will be more acceptable than the most complete

description. It is difficult in a genus so rich in ornamental species to say which is the handsomest. One of the principal claims of this species, in addition to its beauty, is its hardness. The whole plant is covered with a mealy tomentum. It is herbaceous, and in a warm, dry soil, it is nearly or quite hardy, forming large tufts, and throwing up numerous flower-stems about 2 ft. high, covered with flowers all the summer and the greater part of the autumn. A native of the cool parts of Mexico, extending northward into Texas; in cultivation on the Continent as long ago as 1848, from seeds sent by Lindheimer from Texas.

18. Woolly Sage (*S. leucantha*), Bot. Mag. 4318.—A very singular shrubby species with leaves resembling those of *Buddleia globosa*, and sessile, densely woolly flowers. The calyx is of a violet-purple, and the very short-lipped corolla is pure white; the stamens and style are included within the corolla. A native of Mexico, introduced into this country from the Continent in 1846, by Lady Smirke.

19. Twin-flowered Sage (*S. oppositiflora*).—Very near *S. Heeri* in having the flowers in pairs, but they are more glutinous, larger with a broader tube and lips, and the stamens are scarcely exserted. The leaves, too, are relatively small and oblong, or nearly orbicular, with rounded teeth. A native of Peru, introduced by Messrs. Veitch, through their collector, Mr. Lobb, about 1848. This is not so easily cultivated as some others, being a native of a dry hot climate.

20. Showy Sage (*S. formosa*), Bot. Mag. 376.—A showy scarlet-flowered shrubby species, with broad heart-shaped stalked leaves and leafy flower-spikes. The scarlet corolla is of the same shape as in *S. patens*, and the long upper lip is strongly bearded. It is recorded to have been very generally cultivated in the gardens around London at the end of the last century, but it has probably long since disappeared from our gardens. It is stated, however, that its flowers are of very short duration, dropping before they decay. A native of Peru, introduced by Thouin in 1783.

21. Common Scarlet Sage (*S. splendens*), Bot. Reg., 687.—This old favourite was introduced from Brazil by Mr. Lee, of Hammett-smith, in 1823, and has retained a prominent position in our gardens ever since, in spite of its straggling habit and its very evanescent flowers. The rich colours of the latter, even to the calyx, are surpassed by few plants in cultivation. A variety called *Soucheti* (*Fl. des Serres*, 1154) is of more compact habit, with a closer inflorescence, and even more dazzling scarlet flowers.

22. Violet Sage (*S. ianthina*), *Fl. des Serres*, 884.—This is of the habit of *S. splendens*, and is closely allied to *S. cyanea* and *amethystina*. It has large flowers, in which the calyx and corolla are both of a dark violet shaded with purple, as are also the ample bracts. It was originally described from garden specimens, believed to be of Mexican origin, and was figured in the work quoted, and several other Continental magazines, about 1853-55.

23. Crowned Sage (*S. involucrata*), Bot. Reg., 1205.—A glabrous half-shrubby species, with stout stems, cordate-ovate, toothed leaves, 2 to 3 in. long, with reddish veins, and borne on stalks exceeding half-an-inch in length. The inflorescence is crowned with a tuft of a purplish-rosy-red, green-tipped bracts, and the horizontal flowers are of the same colour; the corolla-tube is nearly 2 in. long, inflated in the middle and smaller at both ends; lips very short-bearded; stamens included. A native of Mexico, introduced by Mr. George Ackermann about 1827. A magnificent species.

24. Gesnera-flowered Sage (*S. gesneriflora*), Lindley and Paxton's *Fl. Gard.*, ii., t. 47.—In botanical characters and general appearance this comes very near to the well-known *S. fulgens*, differing chiefly in its larger flowers, the upper lip of which is flatter and less shaggy, and the style less feathery. In habit and the duration of the flowers it is said to be superior to *S. fulgens*. A native of the mountains of New Grenada, introduced by Mr. Purdie about 1850.

25. Cardinal Sage (*S. fulgens*), Sweet's *Fl. Gard.*, second series, 59.—This old favourite is one of the largest-flowered species of the genus. It is easily known by its cordate wrinkled leaves, hoary beneath, and its rich scarlet densely woolly flowers, with a dark purple calyx. A native of Mexico, and from what Sweet says, it appears to have been first cultivated in this country by Messrs. Newman, of Chichester, about 1832; but, under the much better figure (1365) of the Bot. Reg., it is stated to have been introduced into the Horticultural Society's garden by Mr. Graham, in 1829. Dr. Lindley says it was cultivated at Madrid forty years before it found its way into British gardens. In some of the dried specimens the flowers are more than 2½ in. long.

26. Blunt-leaved Sage (*S. obtusa*), *Fl. des Serres*, 1412.—A distinct little densely branched plant with small oval leaves, about

1 in. long, and deep rosy-red flowers, borne in pairs along the spike; they have a short tube, a small convex, very shaggy upper lip, including the stamens, and a large broader lower lip. A Mexican species, introduced by the brothers Tonel previous to 1860.

27. Mexican Sage (*S. mexicana*).—One of the earliest of the Mexican species cultivated in this country, admirably figured in Dillenius's *Hortus Ethiopiensis* (t. 254) under the name of *Scalarea mexicana*. It is a tall-growing species with ovate, strongly-nerved leaves on very long stalks and dense spikes of large blue flowers. In one variety, collected by Graham, the calyx is very highly coloured.

28. Graham's Sage (*S. Grahami*), Bot. Reg., 1370.—Very near *S. obtusa*, but in this there is a tendency to colouring in the calyx, and the corolla is of a rich crimson. Mexico; introduced by Graham into the Horticultural Gardens previous to 1830. A very desirable species.

29. Hartweg's Sage (*S. pulchella*).—In appearance this comes between *S. fulgens* and *S. Grahami*, having smaller, more numerous flowers than the former, and larger leaves than the latter. The flowers are of an intense crimson, and borne in long crowded spikes. It was raised in the gardens of the Horticultural Society in 1842 from seeds sent home by Hartweg. It is a common plant in the mountains of Mexico and Guatemala, but it seems to have disappeared from our gardens.

30. Indigo Sage (*S. cyanea*).—A shrubby plant, with large ovate leaves 6 in. long by ½ in. broad, and borne on long stalks. The perfectly blue flowers are arranged in long pyramidal spikes, those of the lower whorls being on larger stalks. The calyx in this species enlarges and persists, and retains its rich blue colour. This plant was cultivated many years ago in the Berlin Botanic Garden, but I have seen only dried specimens. It is doubtless very handsome when grown to perfection. It bore the name of *S. cyanifera* in German gardens.

31. Amethyst Sage (*S. amethystina*), Smith, &c., ined., 27.—A very pretty plant, though not equal to many of its allies. The leaves are much smaller than in the last, and quite woolly on the under side and stalks, and the flowers are few and distant in the spikes. Mountains of New Grenada.

32. Heer's Sage (*S. Heeri*), *Gartenflora*, 115.—A half-shrubby species, with large ovate-cordate stalked leaves and slender loose spikes of scarlet flowers. Certainly one of the most desirable of the American half-shrubby species, flowering freely in a conservatory during the winter months. It belongs to the section having long, narrow, tubular corollas, with short lips and protruding stamens; the corolla is erect and clothed with a very fine short down. A native of Peru, introduced into Continental gardens by Warszewicz in 1853.

33. Camerton's Sage (*S. Camertonii*), *Gartenflora*, 125.—A half-shrubby species, 4 ft. to 8 ft. high, with slender stems and small, oval, rough, hairy leaves, and cinnabar-red flowers. A very pretty plant, belonging to the same group as *S. elegans* and *S. Litzei*, having rather long, narrow, tubular flowers, with small lips and stamens scarcely projecting. Supposed to be a native of Mexico, but the history of its introduction is unknown.

34. Elegant Sage (*S. elegans*), *Refugium Bot.*, 228.—A slender-branching half-shrub, with ovate leaves about 2 in. long, on long stalks and deep crimson hairy flowers. The tube of the corolla is long and nearly equal throughout, and the upper lip is much shorter than the lower. A native of Mexico, and one of the most useful plants for a greenhouse in winter and spring, as it flowers very freely in the early part of the year. It was in cultivation in this country in 1820.

35. Smaller Scarlet Sage (*S. coccinea*), *Gartenflora*, 232.—This ornamental species needs neither description nor recommendation from us, as it is one of the most familiar in the flower gardens of this country. Few plants surpass it in the dazzling brilliancy of its scarlet flowers, which are produced in great profusion until late in the autumn. It is a native of America, having a wide range of distribution, and it was first introduced into this country in 1774. This species has become naturalised in several warm countries.

36. Bolivian Sage (*S. rubescens*), Bot. Mag. 5947; *S. boliviana*, *Fl. des Serres*, 1148.—A tall shrubby plant more or less clothed with a pale hoary pubescence, ovate-cordate leaves 4 in. to 10 in. long, and a pyramidal panicle, a foot long or more, of scarlet and violet flowers. The calyx is violet, and clothed with glandular hairs, and the corolla a rich crimson or scarlet; tube of the latter long, cylindrical, and curved, and the upper lip less than half as long and broad as the lower one. A native of the Andes of New Grenada, introduced by Warszewicz about 1855.

37. White and Blue Sage (*S. albo-cerulea*), *Fl. des Serres*, 1340.—A very striking and a very beautiful species, easily distin-

guished from all others by the colouring of its large flowers. The corolla exceed an inch and a half in length, and the tube and upper lip are of a yellowish-white, whilst the broad lower lip is of a rich blue tinged with violet or purple. It forms large tufts in the open air in summer, with stems about a yard high, the upper half clustered with flowers. The leaves are lanceolate and about 6 in. long. Van Houtte describes it as retaining its beauty for a long period. A native of Mexico, introduced by Ghiesbreght.

38. Bearded Blue Sage (*S. patens*), Bot. Mag., 3808.—This magnificent species of Sage cannot be replaced by any other plant in the flower garden. The deep ultramarine blue of its flowers is scarcely known in any other genus of summer-flowering plants suitable for the open air. Although rather straggling in habit, and its flowers of short duration, it is indispensable. Indeed, it is so universally grown that a description of it would be quite superfluous. It is a native of Mexico, and was introduced through the agency of Mr. Parkinson, Her Majesty's Consul in that country, in 1837. After its introduction it spread rapidly and widely in the gardens of this country, and it was figured in nearly all of the magazines of the day. There is a grand quarto plate of it in the second volume of the second series of the "Transactions of the Horticultural Society." Several varieties of this species are known; one of the most noteworthy is the *S. patens* *floro-albo*, figured in the "Flora des Serres," 503. This differs in no respect from the type, except in having white flowers.

39. Roezli's Sage (*S. Roezli*), Fl. des Serres, 1407.—A glabrous (except the flowers) half-shrubby species, with ovate-stalked leaves 3 in. to 4 in. long, and crimson flowers about 2½ in. long. Calyx large, tinged with red upwards; lips of the corolla long, divergent; stamens included. Evidently a very handsome species, but I have only seen the figure quoted. Mexico, Roezli.

40. Long-styled Sage (*S. longistyla*).—This species was in cultivation in this country in 1831. It is remarkable for its very long slender flowers, and much longer style, often projecting an inch beyond the corolla, which is about 1½ in. long. The stamens also project considerably; flowers crimson; leaves large, cordate, on long stalks. Mexico.

41. Lofty Sage (*S. excelsa*).—A tall-growing herbaceous plant, with nearly glabrous oval-toothed leaves, with a long tapering point and slender spikes of red flowers arranged in pairs. It was raised in the Horticultural Society's Gardens from seed received from Mexico about 1840.

42. Three-coloured Sage (*S. tricolor*), Fl. des Serres, 1237.—A dwarf-branching tufted under-shrub, with slender hairy branches, small ovate leaves about 1 in. to 1½ in. long and rather loose flower-spikes, with the flowers in pairs. The flowers are very striking and distinct in their colouring, the tube of the corolla being white, the short, erect, upper lip hairy and tipped violet-carmine, and the lower broad lip vermilion-red in the upper half. A native of Mexico, and a very ornamental species for the greenhouse. It was sent by the Brothers Tonel to Mr. Verschaffelt before 1857.

43. Shining Sage (*S. rubilans*), Rev. Hort., 1873, p. 251.—A branching, half-shrubby, glandular, hairy plant, 2 ft. to 3 ft. high, with ovate-lanceolate dark green leaves and very numerous scarlet flowers; the latter are stalkless and nearly erect, with the erect upper lip of the corolla very short and the stamens projecting about half-an-inch beyond it. This is described as an exceedingly profuse bloomer, and as being especially valuable on account of its producing its flowers in late autumn and early winter. Its origin is not known with certainty, but most likely it is Mexican.

44. Cacia-leaved Sage (*S. cacaliifolia*), Bot. Mag., 5274.—This is an exceedingly beautiful species, allied to the more familiar and handsome *S. patens*, but differing materially in the shape and colouring of the corolla, and other particulars. It has large triangular or hastate-cordate leaves, broad corollas, with an abrupt curve upwards near the base of the tube, and nearly equal lips, and the stamens and style project more than half-an-inch beyond the upper lip. The blue flowers are very showy, but they are not of the intense hue of *S. patens*, and towards the base they are tinged with purple. A native of Chiapas, in Central America, where it grows in the Pine forests of the mountains, and is therefore nearly hardy in this country. It was imported into Europe by Mr. J. Linden previous to 1861.

VIII.—Echinosphece.

Floral leaves and bracts prickly; calyx ovate; upper lip three-toothed, lower one shorter, bifid, all of the lobes prickly pointed; corolla with a ring of hairs inside; lobes of both lips fringed. Only the one species described below.

45. Thistle Sage (*S. carduacea*), Bot. Mag., 4874.—One of the most distinct and elegant of the genus, closely resembling *Morina*

persica in its leaves, bracts, and general appearance, and not unlike some of the Thistles. But the most striking character is offered by the deeply-fringed lilac-purple flowers, with yellow anthers. It is herbaceous, growing about 2 ft. high, and the prickly-toothed, oblong, white, woolly leaves all proceed from the root; and the flowers are subtended by whorls of longer prickly bracts. A native of California, introduced by Mosses. Veitch, through Mr. Lobb, about 1854. It is stated in the Bot. Mag. that this species has proved hardy in the open ground.

IX.—Heterosphece.

Floral leaves deciduous, calyx tubular, the upper lip truncate, three-toothed. Tube of the corolla furnished with a ring of hairs inside or rarely naked; upper lip short, erect, the lower with very small, somewhat spreading, lateral lobes. Herbs, natives of the Mediterranean region, Africa, Asia, Australia, and North America.

46. Lyre-leaved Sage (*S. lyrata*).—This species is remarkable in having tufted root-leaves, like those of the Dandelion, more or less deeply lobed in different individuals, and usually of purple colour on the under surface. The flowers are of a purplish-violet. A native of North America, cultivated in the early part of the last century in this country. There is a figure of it in the "Hortus Elthamensis," but not in any of the more recent works.

47. Decaisne's Sage (*S. porphyrantha*), Rev. Hort., 1854, pl. 16; Bot. Mag., 4939.—A pretty species of erect or decumbent habit, with cordate-orbicular crenate, rather thick leaves, less than an inch across, on petioles of about the same length, and rich crimson flowers in clusters of four to six along the spikes. The upper lip of the corolla is about equal in size to one of the lobes of the nearly equally three-lobed lower lip. It is of Mexican origin, and has since been identified with specimens collected by the officers of the Mexican Boundary Survey, and by Wright in Texas. In cultivation on the Continent in 1854, and in England in 1856. A very free-flowering species in the open borders in summer. This is in gardens under the name of *Rocneriana*, which is a distinct species noted below among those not yet introduced.

The following are a few species not yet in cultivation, but which merit the attention of collectors.

Eusphace.

48. Aucher's Sage (*S. Aucheri*).—A native of Asia Minor, resembling the Common Sage in its foliage, with branching bractless panicles of large flowers borne on a slender, naked stem. It comes near *S. candelabrum*.

49. Algerian Sage (*S. Balansæ*).—A very distinct half-shrubby species, about 2 ft. high, with long narrow leaves (resembling those of some species of Lavender) and narrow spikes of large blue flowers. A native of Algeria, growing on a chalky soil.

50. Jamin's Sage (*S. Jaminiana*).—An elegant plant, about a foot high, with leaves bipinnately divided into narrow segments, and remarkably large woolly calyxes. A native of Algeria.

Drymosphace.

51. China Sage (*S. miltiorrhiza*).—A very showy species with more or less hairy pinnate leaves and large widely-gaping blue flowers. It is a native of North China, and doubtless quite hardy in this country.

Calosphece.

52. Woolly-leaved Sage (*S. leucocephala*).—A shrubby species, usually about 3 ft. high, but sometimes attaining a height of 9 ft. It has thick cordate leaves covered on the under surface with a dense white or rusty felt, and very dense spikes of large reddish-purple flowers; the calyx, which is clothed with a white down, is nearly or quite an inch long, and the nearly straight corolla projects about 1½ in. beyond it. A native of the Andes of Peru, and, judging from dried specimens, an exceedingly handsome plant.

53. Woolly-flowered Sage (*S. tomentella*).—A Brazilian shrubby species, about 3 ft. high, with large white woolly flowers.

54. Rough-leaved Sage (*S. scabrada*).—From the same country as the last, remarkable for its hard ovate-lanceolate very regularly crenated leaves and scarlet woolly flowers nearly 2 in. in length. In both of these species the lower lip is much shorter than the upper, and protrudes considerably.

55. Golden Sage (*S. chrysantha*).—A shrubby species, with rather small flowers, the calyx covered with a golden-yellow tomentum, and only the lips of the purple or scarlet corolla projecting beyond the calyx-tube. A native of Mexico.

56. Bentham's Sage (*S. Benthamiana*), Field, Serot. 19.—Mr. Gardner, who discovered this species in the Oregon Mountains of Brazil (at an elevation of nearly 5000 ft.), describes it as a very beautiful shrub, about 4 ft. high, growing in a dry rocky place. It is apparently of compact habit, with small close foliage and scarlet, velvety flowers.

57. Sesse's Sage (*S. Sessei*).—A shrub with large ovate leaves on long stalks and brilliant scarlet flowers, singular in the large inflated persistent crimson calyx. An exceedingly handsome Mexican species.

58. Regla Sage (*S. Regla*).—Similar to the last in the calyx, but it is of more compact habit, with small leaves less than an inch long. Mexico. According to Sweet this was formerly in cultivation.

59. Long-leaved Sage (*S. recurva*).—A vigorous species, with large membranous ovate leaves 6 in. or more long, on stalks of nearly equal length, and large violet-purple flowers, the calyx being of even a deeper hue than the corolla. Mexico.

60. Downy-leaved Sage (*S. vestita*).—A shrubby species with cordate leaves clothed all over with a soft down and scarlet flowers 3 in. in length. A native of New Grenada, and one of the finest species of the genus.

61. Long-flowered Sage (*S. longiflora*).—This must be a truly gorgeous shrub. It grows from 4 ft. to 6 ft. high, and bears terminal pendulous spikes of scarlet flowers 4 in. to 5 in. long; the corolla is velvety, and the persistent glabrous calyx is nearly 2 in. long, changing to a rich purple. It is surprising that this fine species, which grows wild in Peru and New Grenada, and is cultivated in the gardens of those countries, has not been introduced, as it surpasses everything we have belonging to the genus in this country. The hairy leaves are ovate-cordate, tapering into a long point about 4 in. to 5 in. long, and borne on long stalks. The flowers of some of the dried specimens are fully 5 in. long, and the flower-spikes appear to hang down after the manner of *Thyscaanthus rutianus*.

62. Quito Sage (*S. quitensis*).—A very showy shrubby species with large, crimson, velvety flowers, remarkable for the broad short calyx and the ovate-lanceolate leaves, 2 in. to 3 in. long. Found in the Andes of Quito, at an elevation of from 12,000 to 13,000 ft.

63. Purple Sage (*S. purpurea*).—A neat perennial, very common in many parts of Mexico and Guatemala. The flowers are not very large, but they are very numerous and pretty.

Heterosphace.

64. Roemer's Sage (*S. Roemeriana*).—This is apparently an annual species, with stout hairy stems, and the leaves (5 in. to 6 in. long), are curiously divided into stalked and sessile leaflets, somewhat the shape of the leaves of *S. porphyrantha*, which sometimes bears this name in gardens. The flowers, too, are very similar to those of the latter species, and it is a native of the same region.

Pycnosphace.

65. Scabious-leaved Sage (*S. Columbaria*).—This species belongs to a small section differing chiefly from *S. carduacea* in the leaves, bracts, and calyx-lobes not being prickly. It is a singular little plant presenting the appearance of a Scabious rather than a Salvia. A native of California.

TREES AND SHRUBS.

ROOT-CARE IN TRANSPLANTING.

To carry on the work of transplanting trees and shrubs with some prospect of success, especially those subjects which have been introduced from more genial climates than our own, it is of the first importance that every care be taken to disinter and preserve the roots: however favourable an appearance a tree may have at the top, if the roots be mutilated by careless or unskilful lifting, it is not even half a tree, and will have a long struggle for bare life. To lift trees well the characters of the roots of the various kinds must be studied—their texture and mode of growth. The various aspects of the foliage and branches of trees and shrubs are familiar to all who take any interest in their culture, but I may venture to affirm that but comparatively few are equally familiar with the aspects and peculiarities of their roots. This experience could not be acquired, I grant, except by those who have been much engaged in transplanting; but it is of much greater value to the planter, so far as success is concerned than any other kind of knowledge. There is a proper way to prepare a site for a tree, and a proper way to plant it: also a proper way to fasten and protect it when planted. If I were to be held responsible for the success of a piece of planting, I should be very careful to see that the lifting of the trees was well performed; for this kind of work the best hands should be employed. I have no hesitation in saying that bad lifting is at the bottom of three-fourths of the failures after planting. It might be stated as an axiom in the lifting of trees, that if the roots be well secured the labour of moving an unwieldy ball of soil may be entirely dispensed with. In practice it will be found, except in comparatively few instances, that to move a tree with a very large ball of soil is a great mistake, as the unwieldy mass of earth attached to the roots dislocates and distresses them; but a small ball of soil, by way of ballasting the top with the roots, will ensure a far greater probability of success in the future growth of the tree after transplantation; in fact, a small covering of earth round the roots of a tree, whilst being moved, is undoubtedly preferable to no ball, and vastly superior to a large ball of soil that can only be moved with great difficulty.

Among the many different trees and shrubs, the possibility of lifting them with balls of soil, or even securing their roots, varies much with different individual species, for out of the same description of soil some species will move easily with good balls, while it will be almost impracticable with others. This arises simply from the mode of growth the various roots assume; some ramify in all directions, like the Rhododendron or Holly; others take a horizontal course, as some Conifers. On lifting with a particular aim in view to secure the roots, there is one rule which applies to all sorts, whether small or large, and that is to begin by inserting the spade at a sufficiently wide radius from the stem of the tree or shrub, to work round in a circle, and at once to go down sufficiently deep to be below the roots before approaching nearer to the tree. I have just seen a consignment of ornamental trees, excellent so far as the appearance of the tops go, but utterly spoiled from the manner in which they have been lifted, the roots being cut so short off by the spade, that only snags are left to the trees, the really vital roots being left behind. The first cost of lifting should not be considered when it is a question of life and death with the plants. I have found, from considerable experience in lifting shrubs and trees of all sizes, that to get well below the roots in the first instance, and gradually approach the tree is the simplest and easiest way of securing the roots and reducing the bulk of soil so as to make a ball manageable.

The digging-fork is an indispensable tool in tree-lifting, so is a long-handled, very light pick, with long slightly-curving tines for undermining; another exceedingly useful implement in transplanting medium-sized plants is a flat hand-barrow without feet, 24 in. square in the bed, with the four handles rising up with a considerable swan-neck-like crook, so that it can be lowered into a hole and slipped underneath the plant when ready for removal. In addition there should be a low truck on two broad wheels not more than 18 in. high, with one long and strong central handle sufficient to bear the strain of a ton

weight. With a machino of this simple description I have moved to long distances many large trees with corresponding balls of earth. A very common practice in moving large shrubs and trees is to make use of the tops as a lever to move the mass, and to drag the plants about by the roots; this is a great mistake, and should be avoided. Some species are particularly weak at the collar, the roots not becoming strong at the junction with the stem for many years; for instance, all the varieties of *Cupressus Lawsoniana* have an abundance of cord-like tough roots, but not strong enough to buttress the plant; *Cupressus nutkaensis*, White and Red Cedars, *Picea Pinsapo* and *P. nobilis*, are, as a rule, weak at the neck; with all such plants the lifting should be by the ball alone, for which purpose I use an iron implement, in shape something like a gridiron with a long handle, which is easily slipped underneath the mass to be lifted, and the whole can be easily moved by its means on to the truck or the ground without materially distressing the plant. Some trees and shrubs will, however, bear to be handled with impunity by the stem, if the tops be well buttressed by strong roots.

Taxodium distichum and Horse Chestnuts are of this description, also the majority of Hollies, Portugal Laurels, Yews, Thujas, and some Conifers, as the genus *Pinus* generally. Some, again, are possessed of such an intimate unity of root and top that a very small amount of care is only necessary to secure a good bunch of roots; of this description are all the various sorts of Box, Lilacs, Spiræas, notably the Sweet Bay, American plants generally—as *Kalmias*, *Heaths*, *Rhododendrons*, *Gaultherias*, *Fernettys*, *Azaleas*; of these last it must be said that to secure roots in abundance large balls are absolutely necessary; an irreparable injury would accrue to the plants if the soil were shaken away from their roots, on account of their fineness, as they pervade the soil like the mycelium of a Fungus, so that if the soil be removed, the roots must be removed with it. There is another class of plants which, from the nature of the roots, it is always difficult to move with balls of soil, or even secure the roots themselves satisfactorily, the roots being long and thread-like, and not sufficiently grasping the soil—*Berberis Darwinii* and *Mahonia Aquifolium* are examples. Evergreen Oaks, Double Furze, and *Arbutus* require special care, and should be moved in very early autumn or in summer. Indeed, in the case of all plants of which there is a certainty that they will be transplanted in winter, it is advisable simply to move them in autumn, even on to December it will not be too late, and allow them to remain in position if they are intended to be transplanted in March. The plant which has been lifted out of the ground in November, and simply replaced in the same position, will be found in winter to be bristling with young fresh-feeding roots when transplanted in February or March, while, if not moved until the time of transplanting, no young roots will be forming, and the plant will be in the worst possible condition to withstand the shock, and the effects of cold dry winds.

There are yet other plants which, by the nature of their roots, require special care in the removal—plants with soft fleshy roots, which are easily broken, and do not hold the soil well together, though of very rambling habit. The *Catalpa* is a familiar instance, also, the *Tulip tree*, *Aucuba*, *Magnolias*, *Altheas*, *Porsythias*, but, fortunately being all very soft-wooded, they are not easily killed; when a ball is secured, and a plant of this description has to be moved some distance, it

will be necessary to wrap it round with a piece of matting or cord to keep it from falling to pieces. I have found a square piece of strong sail-cloth a simple and very efficient means of lifting and carrying about soft-rooted shrubs; the four corners of the cloth are easily gathered up and fastened; and they also present to the operators a means of getting a good lifting grip; in fact, in many instances, it is preferred to the hand-barrow mentioned above. These remarks apply to plants of all sizes, but more especially to subjects arrived at specimen sizes, where the object is to maintain the plant intact without any reduction or mutilation whatever; under these circumstances the vital importance of taking every care of the roots, and studying the peculiarities of the plant will be apparent.

W. D. C.

TEA PLANTS.

It seems somewhat strange, considering the great interest attached to the Tea plant, that it should be so seldom seen in our conservatory borders or beds; for, apart from the uses to which its leaves are put, its glossy foliage, sturdy habit, and pretty white flowers with yellow stamens ought to ensure more attention than it at present receives. The first introduction of the Tea plant into our conservatories and green-houses dates back to the time of LINNÆUS, who seems to have been the first person in Europe who possessed a living Tea plant. When well grown it forms a bushy shrub, sometimes reaching to the height of nearly 10 ft. In general appearance it reminds one of a *Camellia*, of which it is a near relation. There seems to be at least two species of the Tea plant, viz., *Thea viridis* and *Thea Bohea* (figs. 1 and 2). Some authorities, however, look on them as mere varieties of the same plant. Without entering into a discussion on this subject, we may safely affirm that *Thea viridis* is a much more hardy plant than its congener. Its leaves are longer and their edges more distinctly turned back. The time of its flowering, too, is a full month before that of *Thea Bohea*. In addition to these there is also the Assam Tea plant, (*Thea assamica*), a robust-growing handsome species. The cultivation of the Tea plant is not very difficult, and differs but little from that of the *Camellia*. It may be propagated by seeds, which ought to be sown immediately after they arrive at maturity, or by cuttings, or layers in heat. It may also be grafted on the *Camellia*. The Tea plant, according to a writer in the "Revue Horticole," generally flowers in September.

Fig. 1.—The Green Tea Plant (*Thea viridis*).

STREET TREES.

It is not possible to devise any greater improvement in the appearance of roads or streets in large towns, also for the comfort of foot passengers in hot weather, than would be afforded by rows of trees planted avenue-like on each side; by way of a practical illustration, a proposal to decorate Camden Road (which is $1\frac{1}{2}$ miles in length), was recently adopted by the St. Pancras Vestry, and was referred to in THE GARDEN (see p. 376). There has for some time been an evident awakening to the fact that throughout the kingdom generally we are far behind other countries in the appearance of our large towns in the way of tree decoration in the principal provinces. London in this as in many other things will be keenly watched by provincial towns for an example of what should and can be done; and it is hoped that the first endeavours to create a gigantic boulevard in the metropolis will be crowned with that unequivocal success that such a nobly planned enterprise demands at the hands of those who have undertaken it. The question may be asked, Have the recent attempts at tree planting in London, such as the Thames Embankment and the new thoroughfare from Charing Cross to the

Embankment, been of such a character as to give a reasonable prospect of the trees continuing to grow to a size that will make them effective in either appearance or the ability to give the desired shade? I say decidedly not, and that their failure before they attain anything like such proportion is as certain as if it had been already accomplished. In the management of town trees there are many serious obstacles with which to contend, one in particular of the most vital nature being an insufficient supply of water to the roots. The merest tyro in the study and cultivation of the vegetable kingdom need not be told that if a tree or plant of any description be placed under conditions where it cannot receive enough moisture for the roots, there is an impossibility of maintaining it in a healthy thriving condition, and if when its roots extend they get in a position that affords an insufficiency of moisture still further aggravated by the increased extent of branch and leaf surface, the impossibility of a healthy existence becomes evident. This is just the condition under which the trees on the Embankment are placed. During the past winter I saw in different places the flags which compose the foot-way taken up, and the material under them was as dry as if it had lain in a covered building for years, and this, be it remembered, after an exceptionally wet summer and autumn. Now if the roots of these unfortunate trees enter this dry ungenial mass, they cannot possibly support the healthy and vigorous growth of the trees, and if they remain confined within the small grating-covered spaces, how long can the trees be kept in a growing state, even with every assistance that can be given them? And if this were possible, as the heads got larger, they would be certain to be blown down by high winds, from the fact of the roots having no hold of the soil for a sufficient distance from the bole to withstand the strain upon them, even if assisted by supports of ten times the strength of the objectionable props that now surround them. If trees in such a position are ever to attain their natural size, the material for a considerable depth under the whole of the flags which compose the foot-way must be of a description to afford the necessary sustenance, and above all, there must exist the means to keep the soil in which they are growing sufficiently wet. In this there is nothing impossible. In all cases the foot-way slopes slightly towards the centre of the street; this, instead of consisting of an unbroken surface of closely-jointed flags, should be traversed from end to end, at equal distances apart, by continuous lines of narrow grids, say 6 in. or 8 in. wide, that would allow the rainwater, as it runs towards the channel, to pass down into the earth below the flags, just in the way that grids are placed across a steep garden walk to convey the water into the drains. The perforations in these grids necessary to admit the water would be so small as not to make them in the slightest degree unpleasant to walk upon, and the surface could easily be so roughed as to prevent their being at all slippery—all that would be required would be for them to be made to fit into the flags, and not to rest on the surface of the earth, which should be lower than their underside; otherwise they would soon get clogged; they should also be of easy removal so that the surface of the earth under them could be loosened as occasion required to admit of the water percolating through it. Manurial stimulants so far as required could by this means be easily applied and so washed into the soil. It may be said that all this would cost money—no doubt it would, but nothing serious in addition to that which it has already been deemed necessary to expend entirely without good results. In planting trees in towns, there can be no greater mistake than the use of half measures, as they simply result in failure, disappointment, and waste of money. We see innumerable instances of the power in vegetable life to succeed fairly under some adverse influence of soil or situation, but in the case of trees planted in the street, they exist under such a combination of adverse conditions of soil, atmosphere, and everything essential to their well-being, that unless everything possible be done for them, it would be better never to make the attempt. There is one thing in particular to be observed, viz., that where gas pipes are necessarily placed in the soil near where the roots will come, it is useless to plant. No one can fail to be convinced of this who has ever noticed the state of the earth for several feet adjoining pipes that have been laid for any length of time, permeated as it is with noxious gases until it is as impossible for the roots of any plant to exist in it as it would be in pure coal tar itself. A word as to the kind of trees to be selected for town planting, especially for London: variety would no doubt be desirable, if it were possible to select different kinds that would thrive equally well, but it is not. Of this the trees that have been planted in numbers of places in the metropolis during the last twelve or fifteen years afford the clearest proof. All that have been tried besides the Plane have made such indifferent progress that its superiority has been unquestionably established, a position which it holds when in a much older state. Those who are willing to sacrifice an even, uniform growth to variety may choose different kinds; against that I have nothing to

urge; in fact, I quite coincide with the idea, so far as the squares, parks, and private suburban gardens are concerned, but for the streets, where there is such an accumulation of difficulties with which to contend, I maintain that to give preference to variety in the place of uniform vigour and lasting properties is a serious mistake. If there be another tree I should be disposed to recommend, it would be the *Ailanthus glandulosa*. This, like most other Chinese plants, will thrive on very coarse food; its leaves are also insect-proof, and it retains them in a green healthy condition until late in the autumn, which is of great importance. Elms and Limes, especially the latter, are always a prey to red spider when they exist under conditions adverse to robust vigorous growth, so much so that they are often leafless by the end of July—a state in which they have by no means an inviting appearance. T. BAINES.

Propagation of *Xanthoceras sorbifolia*.—M. Decaisne suggests that this might be grafted on *Kölreuteria paniculata*, a tree to which it is nearly related, and it might also be well to try it on some of the slender-growing *Pavias*. It has occurred to me that if cuttings of it do not strike readily, shoots might be grafted early in the spring, before the buds burst on bits of its own root, as is done in the case of the *Clematis*, and if roots of the *Kölreuteria* or *Pavia* would answer utilised in this way, so much the better. Imported seeds might possibly be secured, and if at all like those of its allies, the *Pavias*, they would germinate readily. Another plant belonging to this group, but rather uncommon in gardens, is *Greyia Sutherlandi*, a small specimen of which bore a panicle of bright red flowers in the Chelsea Botanic Garden a year or two ago. This plant is very beautiful, but rarely blooms on its own roots unless starved for the purpose; hence it might be desirable to graft this plant also on roots or stems of either *Kölreuteria* or *Pavia*, in order to induce it to bloom more regularly than it seems inclined to do.—B.

Transplanting Deodars and Hollies in May.—Now when Deodars are in the flush of young growth, is the best and safest of all periods in the year for transplanting them. The sap is in motion, the roots are active, and if the work be at all carefully and skilfully performed, success is now certain. The same rule applies to Hollies, and probably to most, if not all, our evergreens. The inexperienced may be reminded (says the "Florist") that, in the case of all choice specimen trees, there should be no cramping of the roots. The pit prepared for them should be wide enough to take their full spread; it should be broken up deeply and thoroughly, new soil being worked in if requisite. The surface, before receiving the tree, should form a flat cone, the apex of which should bring the neck of the tree a little, or in some soils—moist ones—more than a little, above the surrounding surface. Every separate root should be separately embedded at its full length in the earth. In dry soils and dry seasons the roots, when slightly covered, may be well soaked with water, leaving the finishing-off for twenty-four hours, till the flush of water has soaked away. Support against wind is necessary, for the same reason that the barbarous practice of lifting and shaking the tree, "to settle the earth about its roots," should never be resorted to. Both these processes tend to draw the roots from the position in which they are or should be laid out, and necessarily bends or cramps them at some point or other, since they are not, like wires, capable of forcing their way through the earth back to the original position from which they were moved by either the lifting or the wind-waving.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

An Ancient Oak.—In the middle of a pasture field near to and belonging to the Spinola, about a mile from Hexham, stands a remarkable and venerable old Oak tree, a giant of unnumbered winters. Its trunk is only 3 ft. high, and it then branches off into three main stems still fresh and vigorous. The circumference of the trunk at 3 ft. from the ground, just beneath where the leaders branch off, is 23 ft. 4 in.—G. F.

Old Elms in Ringmer Churchyard.—It has at length been found necessary, says the "Builder," to top the ancient Elms at Ringmer Church, Sussex, in consequence of the decay of the old trunks, which are 26 ft. in circumference, and quite hollow, rendering the position of the large limbs above insecure. An entry in the parish register shows that these venerable trees were planted in 1607, and are thus 269 years old.

Dwarf Arbor-vitæ Edgings.—Those who do not like Box, or are in climates too cold for it, should by all means use the Globe Arbor-vitæ. It can be laid just as Box is laid, and bears trimming just the same as Box, if not better. We ("Gardeners' Monthly") recently saw some beautiful edgings of it at a nursery in West Chester.

The Sour Wood or Sorrel Tree (*Oxydendrum*).—This is common in the rich woods from Pennsylvania and Ohio south-west. It flowers in June and July, and is said to produce the finest honey. It is said to excel Basswood and White Clover in that respect, the honey having a richer flavour.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Vineries.—Where Vines were started with fire-heat some time back, they will have finished blooming, and as soon as the berries are the size of small Peas, they should be thinned. This operation frequently appears to be one of some difficulty to amateurs. If the aid of an experienced Grape grower near at hand could be procured, I should advise any amateur who is intending to make his first essay at Grape thinning to get his assistance, as a practical illustration of the extent to which the berries should be thinned is much more easily imparted in that way than by the most carefully written directions. Such assistance not always being available, I will try to describe the operation as intelligibly as possible in writing, starting with a few words as to the thinning of the bunches. There is no cultivated plant in existence, if fairly treated, that will fruit more freely than the Vine, the result of which is that more than half the Vines in the country are ruined before they have grown to a sufficient size to fill their allotted space. Fruit trees in the open air that are subject to the vicissitudes of the weather (which in adverse seasons often destroys their blossoms entirely, thereby preventing the trees forming and maturing fruit for that year) often get an inclination to

over-crop in seasons when an abundance of fruit sets; but under glass, with fair treatment, there is every probability of the vines producing annually as much fruit as they can sustain. There is not a more general error in Grape growing committed by beginners than to allow the Vines to be overloaded with fruit, the effect of which process is to injure them permanently. Many amateurs, through an impatience to obtain fruit, allow those Vines that have been planted one year to bear such a crop that so far taxes their energies that the requisite wood-thickening for the year does not take place to any appreciable extent, and a hard stunted condition that never afterwards permits of free growth is the result, the only remedy for which is to bring up a young cane from the bottom, and very frequently replanting altogether is necessitated. A couple of moderate-sized bunches of Grapes is quite a sufficient crop; in fact, if Vines be not allowed to grow any fruit for the first year, they will be much the better for it afterwards, and will go on satisfactorily for a lifetime. It must not be supposed from this that it is only in the early stages of a Vine's existence that over-cropping is a mistake, but it is then more injurious in its effects; yet it is quite possible to reduce

even the most vigorous Vine that has already covered all its allotted space to such a state of weakness by repeated excessive cropping as to make it incapable of producing Grapes worth the name. Amateurs will do well to bear in mind that permanent injury is not the only result of over-cropping, but the quality of the fruit for the time being never approaches that produced by Vines that are not overloaded. The question often asked is, What weight of fruit will a strong, established Vine bear? Supposing that the roots are in good condition, with plenty of room to extend in suitable soil, either natural or in the shape of a prepared border, the bearing capabilities will, in a great measure, depend upon the extent of the space that can be spared for the Vine, when, as is most usually the case, each Vine is confined to a single ordinary rafter, say 18 or 20 ft. in length, from 20 lbs. to 25 lbs. (the number of bunches is immaterial) may be looked upon as sufficient, and this weight good, established, well-managed Vines will continue to produce for many years without failure. If the highest points of colour be desired with large hammered berries, such as are seen in the best exhibition examples, a reduction of one-fourth the above weight will, in all but the most exceptionally strong Vines, be necessary. Where Vines are allowed to make two or three canes each with enough room to prevent crowding the shoots, their root-power will be

proportionately greater, and they will mature a considerably larger quantity of fruit than a single rod. In thinning the berries enough should be cut out to allow all that are left to swell to their full size without compressing each other, yet so that when the bunch is ripe it will keep its shape when laid on a dish without any portion falling loosely over in the way that always occurs when the bunches, as too often seen, are over-thinned. To remedy this the shoulders of the bunches should be left much fuller of berries than the middle and extremities, as the upper portion can rise as the berries swell in a way that those lower down cannot. Cut out the berries well from the insides of the bunches all round the principal stalk. Avoid as much as possible touching with the scissors, and not at all with the fingers, any of the berries that are intended to remain; for the bloom that adds so much to their appearance when ripe is upon them from the first, and if a speck the size of a pin's head be removed when the Grapes are small, it will be the eighth of an inch in diameter when the berry has attained its full size. From this it will be obvious that the earlier the thinning operation is completed after the berries attain the size of half-grown Peas, the better chance there is of cutting out all that have to be removed without touching those that are to remain. It may be said

that Grapes devoid of their bloom are just as good to eat as when it is perfect, but the beauty of their appearance is sacrificed. I have frequently seen amateurs, who have taken to Grape growing for the pleasure they derived from the cultivation of this the finest of all fruits, persevere in it until they had reason to be proud of the result which they obtained, their Grapes being able to bear favourable comparison with examples generally seen on the exhibition table. Never, except in the case of bunches much above the usual size, tie up the shoulders of the bunches in the way sometimes seen, as where this is practised the bunch, when cut, will not hold together, the shoulders that have been so looped up always remaining loose and having an unsightly appearance when cut. The practice of thus tying-out the shoulders is from an idea that it enables the berries to swell better, which is simply a mistake, as, except in the case of very large bunches, the shoulders will gradually rise as the berries below them grow. Keep the shoots regularly stopped in allowing as many leaves as there is space for exposure to the full light, but not so as to crowd over each other, or they can never acquire the strength and substance essential to their requisite assistance to the roots. Give top air early

in the morning—when there is an appearance of a bright day a little should be admitted before eight o'clock; if the sun be allowed to get in force upon the glass before the lights are opened so as to dry the leaves from the moisture that accumulates upon them during the night, they are liable to scorch; give more as the heat increases later in the day. If any air be admitted at the front lights during the early stages of the crop it must be so far limited as not to cause a draught, or it will produce rust on the berries. Water the floor of the house several times during the day in bright weather, and especially at the time of closing, which should be early enough in the afternoon, to cause the heat to rise to 90° or 95°, with the sun upon the glass; when the weather is cloudy, shut up sooner. The necessity for this early closing cannot be too much impressed upon beginners in Grape growing; there is nothing of greater importance alike to the development of the present season's crop and maturing the wood for another year. Where there is an inside border occupied by any portion of the roots, see that these receive plenty of water—here liquid manure can be applied with advantage. It never should be forgotten that there are very few cultivated plants that require so much sustenance as the Vine; the immense amount of growth a healthy Vine will make during the summer requires a quantity of support; and, although volumes have been written upon

Fig. 2.—The Black Tea Plant (*Thea Bohem*); see p. 437.

the evils attending the roots of Vines being too wet, and the excessive moisture producing shanking, yet for one Vine that thus suffers from too much wet, there are scores that are affected by the like complaint through an insufficiency of water.

Peaches under glass that were started about the time first recommended will now require their final thinning—overcropping with these being equally a mistake as it is in the case of Vines. Keep them well syringed every afternoon, allowing the temperature to rise higher after closing the house as soon as the stoning process is complete. Remove any leaves that obstruct the light and sun from the fruit; only by full exposure can it be highly coloured. Remove all superfluous shoots, and keep those that are retained tied in. Give plenty of water to the roots, for there is no cultivated fruit that requires its roots being kept more moist; any deficiency in this respect has the certain effect of preventing the fruit swelling to its full size and the development of the wood for another year, and is sure to favour the appearance of red spider. The latest Peaches under glass will now need their fruit to be thinned, but do not at first remove too much. Thin the shoots, syringe freely, keep the soil sufficiently moist, giving air in good time in the mornings, and not closing so early as to endanger the house getting too hot.

Kitchen Garden.—More French Beans should now be sown, choosing a sheltered position, as this vegetable is very susceptible of injury by a low temperature, and we frequently experience at the end of the month nights so cold as to injure them if in an exposed situation. A few runners should also now be put in, where sticks are scarce let the rows be about a yard apart, pinching the plants off the shoots when they have grown 15 in. or 18 in. high, and allowing them to rest upon the ground.

Greenhouses.

In many cases stages in the above structures are very ill adapted to the purposes of plant cultivation on account of the large body of dry, heated air they admit under them during the summer months, to obviate the injurious effects of which various expedients have to be resorted to. Where these are of wood rising in regular gradations one above the other, the spaces between each admit such a draught among the pots as to cause the balls of the plants to dry much too rapidly for their welfare, and therefore means should be taken to counteract this as much as possible. Shingly gravel or a layer of Moss spread under the stage, and kept syringed from time to time, or damped in some other way, will be found of great service in preserving the air in a healthy moist state. The pots, too, may with advantage be well syringed at least once a day, taking care while doing so not to wet the foliage of the plants whilst the sun is shining strongly upon them, or serious injury will be the result. For general purposes there is nothing to equal a stage run up in 4½ in. brick, with the top courses set in cement to keep them in their places, as then the spaces between can be filled in with loose gravel or other suitable material that, while affording free drainage to the pots, will likewise part gradually with moisture, and keep the atmosphere immediately surrounding the plants in a cool, healthy condition—very different to what it can be where the stages are open for the air to pass under in strong currents. All watering that is necessary should now be done in the after part of the day, to give time for it to soak the ball thoroughly before any portion is again drawn out by atmospheric influence. To ensure a perfect saturation, they should be watered twice over, in case they may have shrunk somewhat from the sides of the pot, or there is not sufficient depth from the rim to admit of its holding sufficient to permeate the whole of the ball. This applies more particularly to Heaths, Azaleas, and other hard-wooded plants, having tough matted balls of earth difficult for water to penetrate. If these are allowed to become dry, it is a difficult matter to moisten them through afterwards, unless the pots be immersed in water sufficiently deep to cover them—a practice that should be resorted to in all cases where there is reason to suppose the ball is dry in the middle. Azaleas that are at all cramped for root-room will now be benefited by an occasional application of weak manure-water to assist them in carrying their flowers, which, when well managed, they always bear in such abundant profusion. If liquid manure be used, great care should be taken or much mischief will result if applied at all strong, or of a kind unsuited to their nature. A table-spoonful of guano to a four-gallon pot will be found quite sufficient, as it is better to apply it more frequently than to run any risk in administering strong doses to valuable plants. Any Azaleas that are now out of bloom should be kept in a genial growing atmosphere, to enable them to make a healthy, vigorous growth. It is surprising the amount of heat Azaleas will stand and enjoy if the air of the house in which they are placed be charged with moisture in proportion. A free use of the syringe will therefore be necessary to favour that condition, and to hold

such troublesome insects as thrip in check, which are sure to attack them, if from any cause the atmosphere should become uncongenial to the health of the plants.

Humea elegans.—These will now be making rapid growth, and should be encouraged with plenty of pot room, giving them good rich soil at every shifting they receive, and a light airy position. Without full exposure their lower leaves will very soon become disfigured, a condition that detracts much from the beauty of the plants. To keep these thoroughly healthy and of a pleasing green colour, they must never be allowed to become dry at the roots or suffer a check in any way. When well grown and clothed with fine healthy foliage down to the pot, they will make very elegant plants for conservatory decoration, and last in perfection for a considerable time.

Hydrangeas are likewise valuable for the same purpose when slightly forced into bloom so as to have them in before they are to be seen in the open borders. *H. otaka* is a splendid variety for pot work, having immense trusses of delicately-shaded pink flowers that are very showy and effective. The double-flowered *H. stellata* is a very free bloomer, and makes a compact, bushy specimen, and is admirably adapted for indoor decorative purposes. Cuttings of these should be put in to grow on for next year as soon as the plants are sufficiently forward to distinguish which of the shoots are without bloom-buds, as, when taken off in the young soft state directly they are long enough for the purpose, they soon take root if placed in gentle moist heat.

Diplacium glaucus, with its polished leaves and singular-looking light cinnamon-coloured flowers, makes a very attractive pot plant, that is exceedingly useful for decoration, and effective in almost any position. To obtain plants of good size for next season, cuttings should be put in at once, and when struck placed in small pots to be hardened off for planting out at the end of May. These lifted again in the autumn form larger and better grown plants than those that are confined to pots during the summer, unless the latter are well cared for and kept supplied with plenty of water to prevent the growth getting hard and woody too soon in the season.

Hedychium Gardnerianum, whether viewed for the beauty of its foliage or its immense heads of handsome-looking flowers, is alike valuable as a pot plant for large conservatories or greenhouses during the summer and autumn months. Old roots of these that have been resting during the winter should now be shaken out and divided, selecting the strongest and best crowns for potting on, when the others may either be planted out in the shrubby border or saved for a like purpose in the sub-tropical garden, for either of which purposes they are well adapted. If grown in pots they should have good rich soil, or they will not make fine leaves or throw up stems sufficiently strong to flower in the autumn. Two-thirds of turfy loam to one of old hot-bed manure, or any other that is well rotted and of a mild nature, will suit them; and any close frame will give them a start, after which they may be plunged out in the open border till wanted for use.

Cassia corymbosa.—This fine old plant is still one of the most valuable and showy we have for autumn decoration, and should be largely grown where houses have to be kept gay at that season. An old plant cut back now and placed in heat will soon break and afford a supply of cuttings that root readily if kept in a close moist place; these, if potted on and liberally treated during the summer, will make a useful flowering subject that is sure to become valuable by-and-by. Where larger plants are required, any saved over from last year should at once be cut back and placed in gentle heat. As soon as they begin to start, shake them out from the old soil and re-pot in good fibry loam and peat, using pots of the same size as before; place them in a close pit or frame till they begin to grow freely, when they should have the lights entirely removed after gradually hardening them off. Shift on as required during the summer, and keep them well supplied with weak liquid manure as the pots fill with roots, which will ensure fine healthy plants, with the ends of each shoot laden with corymbs of bloom.

Campanula pyramidalis and *C. p. alba* are most serviceable plants for decorating a conservatory during the early summer months, and, from their free-flowering habit and stately growth, always command admiration. *C. calycanthema* is also an exceedingly ornamental variety, and well deserving of pot culture. This has a very large widely-expanded calyx of the same colour as the corolla, and as the flowers are borne in the greatest profusion, it produces a very striking effect. Both kinds should now be shifted on into their flowering pots, and, if wanted in bloom early, replaced under glass. The soil for these can scarcely be too rich, and may consist of at least one part of mild rotten manure to three parts of good loam. Offsets should be taken from the pyramidal varieties while they are undergoing the process of potting, that they may be grown on for flowering

next year. *C. calycanthema* being a biennial, seed should be sown early so that the plants may be as large and strong as possible before blooming, that they may make the finer display.—J. SHEPPARD, *Woolverstone Park*.

Roses.

Examine all out-of-door Roses, and pick off any insects that may be damaging the young shoots; caterpillars will be found to be very destructive at this season, and the changeable weather which we have experienced lately will probably bring on blight, which in many parts is very destructive to Roses. The foliage of many of the early tender-leaved varieties is much injured by frost; therefore, every means should be used to restore it to health and vigour, such as administering liquid manure, to which soot has been added, to the plants. Soot used in this way is one of the best manures we can have for Roses. Where blight has set in, syringe the plants well with a weak solution of soap-suds, or soot and sulphur, in order to stop it. I have found soot used with soap-suds syringed on the trees in the evening, and washed off in the morning, to have restored trees to health that have shown themselves to be much blighted, and the leaves all crumpled up. Tie in young growths of climbing Roses, pyramids, &c., so as to keep them in shape. If the young wood be allowed to ramble too much, it hides the bloom, and thus impairs the effect which the plants would otherwise have. Thin out standards when they require it, and peg down those in beds where necessary.—H. G.

Kitchen Garden.

Hoeing between rows, should the weather be favourable, is the operation that must take precedence of all others at this time, and as all seedlings, without an exception, have come up well, weeds are sure to accompany them in great profusion; and, unless destroyed at once, they will both injure and spoil the appearance of the crops. Potatoes, too, require earthing up to protect them from frost; a few of our earliest were nipped slightly in the middle of April, and as there were several stems of haulm to each set we pulled off those most injured, those that were left are now growing as freely as if no harm had ever happened to them. Broad Beans also require earthing up, and the earliest will soon be ready for topping. French Beans are just making their appearance above ground, and must have the soil drawn over them to shield them from frost; another sowing of both these and Runner kinds should now be made. Seakale is now over for the season, so that now all blanks in the plantation should be made good. The latest supply can always be obtained by covering up with oyster-shells; spread these afterwards on the ground with a dressing of salt and dig them in; the crowns should be reduced to three shoots, it being weakening to the plants to allow all that form after cutting the Kale to grow; new beds may now be made with cuttings, or in lieu thereof, seeds sown. Asparagus forcing is also now over, the open-air beds furnishing an abundance. I never recollect it to have been so late as it is this year; hitherto, I have always been able to cut by the first or second week in April, but this season the first open-air crop was not ready till the 25th. The beds should be looked over daily, and all that are 6 in. high (not before) should be cut and tied in bundles and kept till required in saucers of water in a cool shed or cellar. The main object for growing Asparagus is that it may be eaten, but the flavour of this delicious esculent is much marred when it is sent to table in such a blanched and, consequently, such a tasteless condition. I never allow Asparagus to be cut lower than the level of the soil in which it is grown; the entire head can then be eaten in place of leaving a long blanched stem. Plant new beds according to requirements. I can discern no difference between the variety known as Conover's Colossal and the ordinary kind. Rhubarb plantations will now need renovation and filling up, especially where roots have been lifted for forcing; these may be divided into single crowns, and will do much better than if they were larger. Keep them clear of seed-stems, which always show in abundance at this period of the year. Autumn-sown or Spanish Onions are now growing fast, and, if wanted very large, they will now take any amount of feeding. A strong solution of soot-water is as good a stimulant as can be given to them. They should have been thinned out long ago, but, if not yet done, there is ample time for good Onions if planted on well-enriched ground. Part of them should be left thicker on the ground, and thinned out for use as soon as the old Onions are over. Turnips are about the most difficult crop one has to deal with in the kitchen garden, for first of all the seeds must be sown as soon as sown to keep off birds; next the Turnip fly is always hovering over them; and, lastly, if the soil be light and dry weather prevail, they soon become stringy and strong to the taste. To obviate this latter difficulty, all but the earliest sowing should be sown on north or east borders, and in this manner I rarely fail to get a good supply. For the fly, give a good dressing of wood-ashes and soot twice or thrice as soon as they appear above ground, covering at

first with netting. A good breadth should now be sown. Veitch's Red Stone we find the best for general cropping. The first lot of Celery will shortly be ready to be transferred to the trenches; a showery or dull day should be chosen for this, and the plants should be moved with all the soil possible adhering to their roots; if necessary, it is easy to protect them with a few evergreen boughs laid across the trenches. Prick off successional supplies, and get trenches ready for them as the ground is cleared of Broccoli, the old stems of which should be dug up the moment the heads are cut. The Broccoli season will soon be over, and it will now be well to compare notes as to the kinds to grow in future. The best I have found, beginning with the earliest, are—Snow's Winter White, Early Penance, Cooling's Matchless, Sutton's Late Queen, and Landers' Goshen Late White. A sowing of late kinds should now be made, and also of Walcheren and Purple, and White Cape for autumn supply. Lettuce should now be sown thinly where it is intended to be grown, and thinned out to the required distance when large enough to handle. As summer approaches I never plant out Lettuce, for, should a dry period ensue, an immense amount of watering is required to get them established, and a few extra seeds prevent all this. Radishes should be sown fortnightly, and as the Turnip-rooted kinds stand the heat and drought best, they only should be sown. A regular supply of Mustard, Cress, and herbs required for salads should be kept up by sowing a little of each at frequent intervals. Renew the linings to Cucumber frames, and make up slight hot-beds, on which to start Ridge Cucumbers and Vegetable Marrows, both of which may now be planted out, provided they have the protection of hand-lights for a week or two. Tomatoes may shortly now be planted out; they should, if possible, have a southern aspect, and be trained either to a wall or a fence, though I have known them do well on a sunny ridge, and allowed to ramble the same as Vegetable Marrows.—W. WILDSMITH, *Heckfield*.

SOCIETIES AND EXHIBITIONS.

THE GREAT FLOWER SHOW AT BRUSSELS.

This exhibition, one of much importance in Belgium, was a remarkably fine one of its kind; but, inasmuch as it only possesses interest for our own readers in the respect in which it differs from English shows, we propose to say but a few words on these points, and refer those who desire more details to the list of prizes published in the outer portion of the paper. In this way we avoid the mere repetition of what is of little interest to our own readers. The most striking features of the show were the fine groups of plants sent by London nurserymen. There were enough English plants to make a very large floral exhibition of themselves. Some of the leading nurserymen, at great cost and pains, sent many of their finest and rarest plants to this show, and in the classes in which they competed were awarded the highest prizes. Messrs. Veitch sent one of the finest collections of new plants in numerous kinds that even they have ever staged. Mr. Williams won the King's prize for the foreign horticulturist who made the most beautiful display. Mr. Ball won the much-coveted prize for the best collection of new plants not in commerce. Mr. Wm. Paul sent a whole garden of Roses; and Mr. Wills came and won with his *Dracenas* in the very home of *Dracena* cultivation. Several large vans were in some cases required to carry the plants from London, and as thirty-six hours is the shortest time in which such heavy goods can be conveyed from London to Brussels, the difficulty of bringing choice plants may be imagined. As it was, the Roses in Messrs. Veitch's collection suffered much—the flowers falling as soon as unpacked. The spirit and enterprise of English nurserymen is therefore deserving of acknowledgment in this as in many other cases.

Arrangements.—These differ from ours, inasmuch as the plants are on the first day placed in any way convenient for judging. On the following day, when the judging is completed, the hall is given over to a gentleman—charged with the grouping of the whole for effect—and his assistants, and before noon the next day the whole place is transformed. It need hardly be said that the time allowed at our exhibitions precludes such plans in our case; at Brussels, for arranging, judging, &c., and the duration of the show, nearly two weeks were required. As regards the result of the final arrangement and grouping, it was effective, though by no means remarkable; the ugly temporary building in which the whole was arranged was in some degree the cause of this. The principle adopted was the simple one of throwing the larger groups of Palms and fine-leaved tropical plants of all kinds into imposing groups and masses, mostly at the ends and sides. Straight walks were also avoided, and this prevented dense masses of people filling up vistas, to the injury of the general effect. Looking along the centre of one of the spans of the building, flowers and plants were everywhere seen, as if there were a crowded street in common in similar cases, though far from desirable. As regards the grouping of the masses, smooth gradually rising banks were everywhere to be seen. This is, in nearly all cases, the wrong way, as much of the form and contrast naturally afforded by the plants is thereby hidden. The right way is to give full expression to any remarkable or stately form by allowing it to stand forth free from

its surroundings. Instead of placing the tallest and most effective plants behind, the best way will often be to bring them to the very margin of dwarf groups. One evil avoided in this show was that resulting from blank spaces, badly set-up groups, &c., the whole receiving in the process of re-arrangement a desirable finish and unity. Under this head we may also speak of the hospitable arrangements made for foreign exhibitors and guests—in corroboration of which the reception at the *Hôtel de Ville*, the dinner given by the King and Queen at the palace, and the banquet on May 1, may be mentioned.

Azaleas.—The most brilliant effect of the exhibition was afforded by exceedingly well-flowered plants of *Azalea indica* in many varieties, all trained in trellis-fashion, with hemispherical heads borne on clear stems about 18 in. high. These were so grown and trained that the whole upper surface of each plant was a dense mass of flowers, and there were many beautiful varieties. Placed close together in large groups the effect was that of small, gently sloping mounds of often vivid and often lovely colour. Probably neither this type of *Azalea* nor the pyramidal ones with which we are more familiar, will satisfy the taste of many who think the plant should be trained in a more free and natural manner, but of the two existing styles the one shown here is the best, because it prevents the tendency to one-sided training, of which we have seen so many examples. Very remarkable are the many new kinds of *Azalea indica* now being raised here—double and semi-double of the most delicate pure colours or pencilled; some are nearly as double as a *Camellia*, and some are as large as the flowers of the large Indian *Rhododendron*; no doubt many of these are destined to be welcome additions to our greenhouses.

New Plants.—These were for the most part plants of leaf-beauty only; flowering plants, with any claim to novelty, were very few, and these not noticeable for beauty. Mr. Bull won the first prize for six new plants, introduced by the exhibitor and not in commerce, with *Aralia splendens*, *Fritschardia grandis*, *Croton elegantissimus*, *Dieffenbachia Schultzei*, *Dieffenbachia Cheloni*, and *Alceosa Johnstonii*. Messrs. Jacob-Makoy, of Liège, were second with *Anemia tessellata*, *Aphelandra illustrata*, *Liparis elegantissima*, *Maranta Massangana*, *Paullinia thalictroides argentea*, and *Ruellia Devosiana*. Mr. Bull was also first with three new plants, *Dieffenbachia gracilis*, *Croton Hendersonii*, and *Aralia spectabilis*; and Mr. Williams second with *Photinia serrulata variegata*, *Dieffenbachia Parlatoei marmorata*, and *Zamia crassifolia*. The new double and single *Azaleas*, elsewhere spoken of, were the most interesting novelties in the way of flowering plants in the exhibition. Among M. Van Houtve's plants were—*Azalea indica Reine des Belges*, *Massage de Louvrex*, *Herman Lubbers*, *Oscar La Marche*, Prof. Ed. Morren, Dr. Herm. Woodland, Louis Blommaert, and Mme. Aug. Lemonnier; M. Roze, of Mayence, had also some new *Azaleas* of remarkable beauty.

Dracenas.—These handsome plants have of late attracted more than their usual share of attention, from the many remarkable varieties raised from seed by Mr. Wills, who sent the cream of his collection here, and won the first prize, the great novelty, (as well as the good culture and beauty of Mr. Wills's plants, placing them before the superb collection of better-known kinds shown by Mr. Linden. There were also fine examples of cultivation, and though some of the plants were 6 ft. high, they were all stated to be the result of one year's growth. As, however, Mr. Truffaut, of Versailles, strikes from cuttings, and makes the finest kinds of *Dracena* in a month or five weeks into handsome plants, rapid culture is now becoming more common. It is an important point in favour of these valuable plants for decoration that they may be grown as rapidly as those which we are accustomed to call soft-wooded plants in England. It is, however, as well to state that such success has been obtained where there are abundant and special means of cultivating tropical plants. While giving full credit to the raisers and introducers of the variegated *Dracenas*, it is as well to point out the great value of the green-leaved kinds. A specimen of *D. grandis*, a noble green-leaved kind, was the finest in the exhibition, and was very well cultivated and graceful. We may add that the exhibition was a marvel of excellence in all respects, and that the exhibition was very rich in Palms, of which Mr. Linden furnished numbers of well-grown specimens from his unrivalled collection at Ghent.

ROYAL HORTICULTURAL SOCIETY.

MAY 3RD.

AMONGST the more remarkable plants exhibited on this occasion, was an effective group of *Azaleas* from Messrs. Veitch & Sons; new forms of *Mignonette* in admirable condition from Messrs. Carter & Co.; and a select batch of Alpine and show *Auriculas* from Mr. Charles Turner, of Slough.

First-class Certificates.—These were awarded to the following new and rare plants:—

H. P. Rose Duke of Connaught (Paul & Son, Cheshunt).—This is one of the very finest of all dark crimson Roses; we gave an account of it last week.

Azalea Duke of Edinburgh (W. Parsons).—This is a very large-flowered variety of good form and substance. The colour is bright rose, inclining to salmon, and it promises to be a desirable addition to existing kinds.

Clematis Proteus (Noble, Sunningdale).—This is a distinct large-flowered variety, bearing semi-double flowers of a rosy-purple colour, the anthers being nearly white. It is a very valuable plant, but, as shown, decidedly ornamental and well worthy of culture.

Primula cortusoides amona laciniata (Dean, Bedford).—A distinct and effective form of the *Cortusa*-leaved *Primulas*, having large out-petalled flowers of the richest magenta colour, and much larger and certainly more elegant in outline than those of the *P. c. amona*.

Pyrethrum aureum laciniatum (Osborn, Fulham).—This is a dwarf cut-leaved form of the well-known *Pyrethrum Golden Feather*, and one which will be very useful for bedding purposes. Its colour is a soft greenish-yellow, and contrasted with *Lobelias*, or as shown with *Genetia scaculis*, it is very effective.

Pelargonium grandiflorum var. Queen of Stripes (Rawson, Bromley).—A compact-habited plant, from 6 in. to 12 in. in height, and most floriferous. It is very distinct from all others in cultivation, the flowers being of a bright rosy colour, with vermilion-scarlet carination-like stripes. The upper petals are also pencilled with velvety black; as a decorative plant it will be most effective and useful.

Auricula Gertrude Knight (Turner, Slough).—A distinct and very large-leaved green-edged variety, bearing a compact truss on stout well-elevated scape. The individual flowers are of good form, and the paste white and dense; its fault, if any, lies in the eye being a trifle too large in proportion to the rest of the flower; the ground colour is deep purple.

Auricula Charles Lidgard (Turner).—This is also an Alpine variety, having large flat dark crimson flowers and a rich golden eye, which sets them off to much advantage.

Primula Golden Queen (Miller, Upway, Dorchester).—A distinct yellow orange-eyed hose-in-hose form of *Primrose* or *Oxlip*, which promises to be of service for spring bedding.

Miscellaneous Plants.—Messrs. Veitch & Sons contributed a very effective group of *Clematis* in bloom, among which we remarked Miss Bateman, white, *Lady Londesborough*, lilac; and Albert Victor, also satiny lilac. From the same firm also came a vigorous plant of the large golden-flowered *Oncidium Marshallianum*, bearing a huge, branched spike, furnished with about twenty-six flowers, resembling great golden butterflies. Messrs. Veitch also sent six very distinct and effective new *Azaleas*, among which we noticed *Marquis of Lorne*, a distinct semi-double scarlet; *Madame Marie Lefevre*, a large white-flowered variety; *Princess Louise*, a delicate, rosy salmon-tinted double-flowered variety; *Charmers*, a satiny crimson, very floriferous, and distinct; and *Baron de Vriere*, a large variety, with frilled white flowers here and there splashed with red. Mr. Dean showed a small group of hardy flowers, comprising a slender-habited *Aquilegia*, raised from seeds of *A. chrysantha*, but generally believed to be a form of the American *A. canadensis*. Mr. B. S. Williams furnished an effective and well-arranged group of Ferns, *Pandanas*, *Crimums*, *Dracenas*, and other fine-foliaged plants. Mr. Buchanan, Southampton, showed four fine trusses of the large-flowered *Rhododendron Nuttallii*, one of the finest of all the Sikkim Himalaya species. Mr. Laing, Stanstead Park, sent a very beautiful *Caladium*, named *Madame de la Derangy*. It is somewhat ressembling the old *Chantrelle*, but has pink veins. Mr. Smith, Spring Hill, Edinburg, contributed a robust-flowering plant of *Odontoglossum Andersonianum*, and also well-grown examples of *Masdevallia Harrayana* and M. Veitchii. Mr. Cripps showed two fine specimens of *Clematis* in pots; one named *Souvenir de J. Standish*, had large eight-sepaled lilac flowers of the *C. lanuginosa* type; and the other, named *Lilian*, had delicate bluish-lilac flowers of exquisite form. Two large baskets filled with *Genetia* verna came from Messrs. Osborn, of Fulham.

Fruit.—From Mr. John Chester, Conington Castle, came a useful seedling Apple; and Mr. Rust, of Bridge Castle, forwarded three dishes of seedling Apples in a very good state of preservation. Messrs. Lane & Son, of Berkhamsted, sent six or eight clusters of Muscat Grapes, in order to show the result of setting under damp treatment; they were certainly most profusely furnished with healthy young berries, about the size of Peas. Some of these bunches could not measure less than from 12 in. to 15 in. in length.

NOTES AND QUESTIONS—VARIOUS.

Destruction of Primrose Blossoms.—What "Essex" (p. 890) complains of is caused by birds, chiefly sparrows, which are very destructive here. I have watched and seen them destroy not only the blossoms of *Primroses*, but also those of Plum and Cherry trees, the ground under which has been covered with their petals in a few hours.—W. D. B., *Wotton House, Maidstone*.

I think I can throw some little light on the subject complained of by "Essex" (see p. 890) under "A. D." (see p. 407). A few years ago when some Ivy against a wall in my garden was being clipped, a starling's nest, just built, fell to the ground. With the ordinary materials composing the nest, I found pieces of three or four kinds of plants, stems, leaves, and flowers—evidently the birds had been sitting at a little decoration. One summer when I had a plant of *Delphinium nudicaule*, the blackbirds plucked all the flowers off it, probably mistaking them for ripe fruit. My *Primroses* have suffered in the same way as complained of by "A. D.", and I give the birds the credit of the mischief; but they may eat small portions of the petals, or if not, destroy them from wantonness.—G. F.

Hardiness of Anemone fugens.—The severe frosts and heavy snow which we have lately experienced in Leicestershire, and which have destroyed nearly every early flower which had ventured to peep forth, have had no ill effects upon this *Anemone*; on the contrary, the warm sunshine which has lately set in, and which has succeeded in melting nearly 12 ft. of snow, has now brought forth *Hyacinths*, *Polyanthuses*, and similar flowers have been destroyed, has brought this spring gem out in all its brilliancy. It looks none the worse for the unseasonable weather through which it has passed unprotected, and it is now attracting general attention.—JOHN BIRDSEY, *Loughborough*.

"This is an art
Which does mend Nature; change it rather; but
THE ART ITSELF IS NATURE."—Shakespeare.

GROUND ORCHIDS.

THE representatives of this portion of the Orchid family are more widely distributed over the globe than those of an epiphytal character, for, although in tropical countries the latter-named varieties predominate, as we trace Orchids through the cooler latitudes we find the epiphytal varieties gradually give place to the terrestrial, until in cold countries the epiphytes are lost, and the Orchids are all terrestrial, these latter having many representatives in Great Britain, North America, and some even in the most northern parts of Russia. In warm countries many of the varieties commonly found growing on the ground are frequently to be met with on the larger branches and the trunks of trees, the genera *Cypripedium* and *Pleione* being particularly liable to these variations; but, as under all circumstances they are found in some depth of accumulated vegetable deposit, under cultivation they succeed best when treated as true terrestrial Orchids. In order to prevent confusion, these remarks will not be confined to those varieties found growing on the ground only, but will include a few sub-terrestrial kinds requiring similar treatment. Evergreen terrestrial Orchids differ mainly from the epiphytal varieties in that they require but a short period of rest, most of them growing throughout the whole year, except during the short period that they are in bloom, and at this time they should be placed in a somewhat cooler and drier house, which will give the plants a rest, and also preserve the flowers, which would otherwise be injured by the damp atmosphere of the growing house; but even during the brief resting season the evergreen varieties should not be allowed to get quite dry. All deciduous terrestrial Orchids, such as *Calanthe vestita*, the *Pleiones*, &c., require as distinct a resting season as the epiphytal Orchids, and on losing their leaves should be placed in a cooler house and not be watered until they show signs of renewed growth. Both the evergreen and deciduous kinds thrive best in pots, which, for the stronger-growing sorts, should be larger in proportion to the size of the plant than those used for epiphytal varieties, and should be crocked one-fourth of the way up, placing a layer of *Sphagnum Moss* over the crocks, and on that a layer of charcoal mixed with equal parts of the most fibry portion of the soil; let this compost occupy about one-third of the pots for strong-growing plants, and one-half for the smaller-growing kinds. In potting a terrestrial Orchid, turn the plant out, and remove as much of the old soil as possible without injuring the roots; then take a suitable-sized pot, previously prepared as directed, place the roots in the pot, keeping the crown of the plant a little above the level of the rim; fill in carefully between the roots with the compost in use, not pressing it too hard, and leave the plant in such a position that when it settles down a little the crown or neck will be level with the rim of the pot, always bearing in mind that, although some of the *Cypripediums* and a few others of like habit are rather benefited than otherwise by being kept a little above the pot, the strong-growing kinds, such as *Calanthe*, *Phajus*, and most other terrestrial Orchids, thrive best below the rims. With regard to the best time for potting, the most intelligible rule, and one that holds good in all cases, is, that the plants should be potted soon after they have done flowering, for most of the terrestrial Orchids flowering out of the mature growth, or with the newly started young growth, and not having pseudo-bulbs to supply them with nourishment and carry them over any check they might receive, if potted at any other time, are likely to be prevented from flowering, and if not in a sufficiently warm place to induce them to grow the plants will be injured; but as it is desirable to place them when in flower in a cooler and drier house, and as they are frequently used for decoration in the dwelling-house during that period, care should be taken, when the plant is out of flower, that it be not potted out of the cooler house or dwell-

ing house and then transferred to the warm house to grow, but that plants should be placed in their selected positions for at least a week before potting, it being a great mistake to pot any Orchid, either terrestrial or epiphytal, from a cold house and place it in a hot one, or *vice versa*. The whole of the evergreen, tropical terrestrial Orchids will succeed well in an ordinary cool stove or intermediate house mixed with other plants, and will require no different treatment, except to be moved to the cooler and drier end of the house while they are in bloom. Least amateurs should be in doubt as to which are terrestrial varieties, it will be well to enumerate some of the leading kinds, together with a few others which are sometimes found on rocks or low down on the trunks of trees, and therefore have been found to succeed best when treated as true terrestrial Orchids.

The evergreen *Calanthes* are noble-looking plants either in or out of flower. *C. veratrifolia*, bearing spikes of snow-white flowers, often 3 ft. in height, and lasting a long time in perfection; there are two varieties of this plant, one being early winter flowering, and the other coming in at the commencement of summer. *C. Masuca* is similar in habit to *C. veratrifolia*, but has mauve-coloured flowers. *C. curculigoides* grows about half the size of the above two varieties, and has yellow flowers. *C. furcata* and *C. Domini*, the latter being a hybrid raised in this country, and having lilac and purple flowers, are also beautiful varieties of this section; they succeed best in a mixture of two-thirds turfy loam and one-third leaf-mould. Many good cultivators mix manure with the compost used for potting strong-growing terrestrial Orchids, and produce very fine plants; but equally good ones are to be grown without it, and as manure of the requisite quality is not always to be obtained, the amateur will find it better to adhere to the natural soils as recommended above. The *Calanthes* are from India, Java, &c., and should be grown in a warm, airy house. *Calanthe vestita rubro-oculata*, pure white, with crimson centre; *C. vestita luteo-oculata*, the same with yellow centre; *C. vestita nivalis*, all white; *C. vestita Turneri*, white, with rose centre; and *C. Veitchii*, rosy-pink, are all deciduous kinds, and should be grown in a warm house, and kept well supplied with water until they flower, after which they should be placed in a cooler house, and water withheld until they show signs of a renewed growth, when they should again be placed in the warm house and shortly after potted. The soil recommended for the other *Calanthes* is the best with the addition of a little silver sand.

Limatodes rosea requires similar treatment to the deciduous *Calanthes*, which it resembles, but should be potted in two-thirds peat and the rest loam and silver sand.

Phajus grandifolius, *P. Wallichii*, and *P. bicolor*, are large-growing evergreen Orchids, resembling each other in habit and in the character of their flowers. *P. maculatus* has large deep green leaves beautifully spotted with yellow, and bears spikes of large clear yellow flowers; they come from North India, Ceylon, and China, and should be placed in a warm house, and after the growth is matured be transferred to a much cooler house, and but sparingly watered for a time; their flowering season is winter and spring, but by careful management they can be flowered at almost any other time. They require the same soil as the evergreen *Calanthes*.

The *Bletias* are elegant-growing Orchids of deciduous habit, throwing up their slender spikes of generally rose or purplish-coloured flowers from among the leaves. They thrive in the same compost as the deciduous *Calanthes*, and should be grown in the intermediate house, after which they should have a good resting season in a cooler house, not withholding water altogether.

Sobralias are handsome plants, often 6 ft. in height, and bear large light or dark rose-coloured flowers on the tops of their reed-like stems; they succeed best in the intermediate house, potted in sandy peat, and only require a little rest while in flower.

Epistephium Williamsii and *E. grandiflorum* are like the *Sobralias* in habit, but have their flowers, seven or eight, on a spike.

Lissochilus Horsfallii is a rare and beautiful variety from Old Calabar; it has the general appearance of *Phajus grandifolius*, and should, as far as possible, be treated in the same way

Cymbidium eburneum, *C. Mastersii*, and most of the strong-growing *Cymbidiums*, are often found growing among rocks; the two varieties named are certainly the best. *C. eburneum* flowers in spring, and has large ivory-white flowers, generally produced in pairs. *C. Mastersii* has long drooping spikes of white flowers, ten or twelve on a spike, each flower about one-third the size of those of the other variety. They come from the hills in India, and are found growing at an elevation of 6000 ft., consequently they will not thrive for any length of time in a hot-house; they should be potted in turfy loam or turfy loam and peat, and placed in the intermediate house, and when in flower and for a short time afterwards, rested in a cold house, water being given them the whole year round.

Peristeria elata and the strong *Zygopetalums* should be potted in one-half turfy loam, and the other half peat and silver sand: the former should never be watered heavily, nor rested in too low a temperature.

The *Pleiones* are small-growing gems among Orchids, and are generally supposed to be difficult to grow, but this is not the case when the habits of the plants are studied. They all come from high elevations in India, and should be grown on a shelf in the intermediate house, being freely supplied with water while growing; after the bulbs are fully formed water should be withheld, and the plants placed on a shelf in a cold dry house until they throw up their new growths and the flowers with them, which will be in October or November; they should then be given a slight increase of temperature until they have ceased flowering, and then potted and placed on the shelf in the intermediate house to grow; this system, repeated annually, will ensure success with these lovely little plants. They thrive best potted in one-half turfy loam and the other fibry peat, with a little silver sand.

Stenorhynchus speciosus and *S. maculatus* are beautiful plants for winter flowering, the latter not being met with so often as it deserves, it being a beautiful plant with variegated foliage and scarlet flowers. The *Cypripediums* are a large class and very easy to manage; most of the *barbatum* and *Stonoi* class grow best in the warm house, but the section *Selenipedium*, with narrow bright green leaves, thrives best in the intermediate house; they grow all the year round, except a short time when in flower, and should be watered freely; the greater part of them succeed in one half peat and the other half *Sphagnum Moss* and silver sand; but the *Selenipediums* like the addition of a little turfy loam.

The varieties of *Anacochilus* and *Goodyeras* are much sought after on account of the beauty of their leaves, which are indeed marvellous, but as the *Anacochilii* require special treatment, I will leave them for a future notice, when they can be more fully discussed; in the meantime, the amateur wishing to try his hand on this class is recommended to begin with the *Goodyeras*, which are not so delicate or costly. They grow best in a warm house, in a shady place, without a bell glass, and potted in one half peat and the other half *Sphagnum Moss* and silver sand.

Pogonia discolor grows freely, and has large leaves of the greatest beauty, shaded orange, red, brown, and green.

The list might be continued with other species, such as *Anguloa*, *Lycaste*, *Catasetum*, *Galeandra*, *Masdevallia*, &c., many of which might be considered sub-terrestrial; but as their culture is not the same as the others, I shall at present refrain from noticing them. Next week I will offer a few remarks on the culture of the greenhouse and hardy varieties.

JAMES O'BRIEN.

FURNISHING FLOWER BEDS.

FLOWER BEDS will be later this year in being planted than usual, in consequence of the backwardness of the season; indeed, beds of Wallflowers, Aubrietias, Pansies, and similar spring-flowering plants, will be masses of bloom until the end of the month, and one is reluctant to uproot and destroy them. When taken up it is often found that they have greatly impoverished the soil, and to make amends for this a quantity of it is removed, and some thoroughly-decayed manure and fresh earth are added before *Pelargoniums* and other summer-flowering and fine foliaged plants are planted. In cold localities failure frequently arises from planting in unprepared soil; beds for *Calceolarias*, for instance, should not only be deeply dug, but an ample supply of manure should be worked into them some 18 in. or 20 in. deep, in order to entice the roots downwards. *Calceolarias* often die off suddenly during summer, a circumstance in a great measure owing to want of preparation previous to planting. Such plants as *Petunias*, *Ageratums*, and the stronger-growing types of *Zonal* and other *Pelargoniums*, although they need deep soil preparation, yet do not require much stimulating material. Where luxuriant foliage is the object aimed at, the manure should be worked into the soil from 12 in. to 18 in. deep; but where only a moderate amount of foliage and an abundance of bloom are desired, the enriching material should be kept near the surface, and the poorest soil the deepest down in the bed. In wet seasons, many of the finer-flowering *Pelargoniums* have a tendency, in deeply-prepared beds, to produce foliage instead of bloom. Surface-manuring therefore promotes a free growth at first, or at least gives the plant a start in life; afterwards the roots go downwards into the poorer soil, when mere leaf-growth is checked, and a disposition to bloom is encouraged. Breaking up the soil to a good depth has the advantage of rendering the plants and the cultivator, to a great extent, independent of the season, let it turn out what it may. If it be cold and rainy, the excessive amount of wet passes off freely; if it be hot and dry, the roots penetrate deeply in search of food and moisture, and in proportion to the deep stirring of the soil does the moisture rise to sustain the plant, a fact well known in kitchen garden culture. Another cause of failure arises from turning the plants out of their pots in a comparatively dry state. Under such circumstances the water enters the surrounding soil, and passes off without moistening the ball. Therefore, whether the plants are in pots, or planted in temporary beds or boxes, they should be properly moistened before they are transferred to their summer quarters. The inexperienced, too, should guard against planting out when the ground is wet, or when rain is falling. When the ground is wet, soils, particularly cold, heavy ones, cannot be worked so as to properly accommodate the small fibres, and the surface becomes baked as hard as a pie-crust, a condition which quite shuts out the beneficial influences of both sun and air. Such plants as *Stocks* and *Asters* are all the better for being put out when the soil is damp, provided the operator is not compelled to tread on the ground, but in the case of all ordinary bedding plants, it is best to put them in when the beds are tolerably dry. When planting from pots, if the roots be firmly matted round the ball, they should be disentangled a little before being placed in the soil, in order that they may enter it more freely. Many plant out *Pelargoniums*, *Verbenas*, and similar subjects in temporary beds to harden off previously to planting them out in their permanent quarters, and when that is done the small rootlets surrounding the ball take to the fresh soil at once. It is a mistake to water as soon as the plants are put out. When this is done early in the season—say in the end of May and the early part of June—it tends to cool the soil, to the disadvantage of the roots, while, on the other hand, the dryer and rougher the surface, the warmer and the better do they succeed. If the plants be in proper condition when planted out, they will not require water very soon after that operation; and should they flag a little during bright sunshine, a sprinkling overhead will be of more advantage to them than a flood at the roots. When it is necessary to water, it should be given at least as warm as the air is when it is supplied, and the Dutch hoe should be run over the beds as soon as possible after the application, in order to open up and aerate the soil. E.

Pine-apple Salvia.—From the selection of *Sages* in your last number (see p. 430), is absent the species known in greenhouses as the *Pine-apple Sage*. The leaves, which are about 2 in. long, have a strong and pleasant odour of *Pine-apples*. The flowers are scarlet in long spikes. I shall be happy to exchange cuttings with anyone desirous of having this species for any of the finer hardy sorts. —SALMONICERFS.

Various Kinds of Hybrids.—According as the union takes place between different varieties of one species, different species of one genus, or between two species belonging to different genera, the resulting hybrid may be termed a variety-hybrid, species-hybrid, or genus-hybrid. When a hybrid is made to unite with one of its parent-forms, or with another parent-form, or with a hybrid of different origin, the product is termed a derivation-hybrid. —SAGES.

Grafting Tea Roses.—Mr. Richard Smith, of Worcester, grafts *Tea Roses* by the thousands on the *Manetti* stock. This is done in November, and some of the plants grafted at that time flower in the following May. Of course the plants are grafted in a warm propagating house or pit. —B.

NOTES OF THE WEEK.

— SWERTHRIER is one of the many "old-fashioned plants" which may be found in Covent Garden at this season. It is brought established in 6-in. pots, in the shape of compact specimens about 6 in. high, handy for those who desire miniature bushes of this old favourite in their rooms. If surfaced with *Sibthorpia* or some other modest herb, the effect of the pots would be improved.

— GARIBALDI is the name of a Strawberry extensively forced for the market by Mr. Bennett, of Habley; it seems to have merit as a forcing kind, being long-bearing, bright and rich in colour, and good in flavour. Mr. Bennett's plants have been gathered from eight times this season, and he says the last gatherings have furnished the finest fruits.

— A SECOND EDITION of Miss Hassard's book on "Floral Decorations for the Dwelling-house" has appeared during the week. This edition is especially for American readers, and contains some changes and additions to meet the wants of Americans.

— THE work yet to be done by raisers of late Apples is suggested by the fact that at present no good dessert Apples are supplied from Covent Garden. The Sturmer Pippin does not sell on account of its colour, and the Calville is too high in price; usually Apples of poor quality, but high colour, are supplied and placed on the table, but not eaten.

— AMONG the various pretty double Buttercups that flower at this season the Queen is the one called *Ranunculus speciosus* fl.-pl., a dwarf plant bearing very large golden double flowers. It is perfectly hardy round London, but seems to bloom best on very sandy soils. We were recently much pleased with the beauty displayed by a bed of it in Van Houtte's nursery at Ghent.

— EVEN in days when the Narcissus were wholly neglected in private gardens, and that is only a few years ago, the Poet's Narcissus was cultivated for the London flower-market, in which various forms of it may now be seen in quantity, as also the Twin-flowered Daffodil. More valuable than these as cut flowers are such noble kinds as *N. maximus*, *N. Horsfieldi*, and various single and double sorts not yet seen in the flower-market, though getting plentiful in cultivation.

— THE Wood Forget-me-not (*Myosotis sylvatica*) is now sent in quantity as a cut flower to Covent Garden Market, grown mostly by Mr. Neighbour, near Hounslow. Thus we now have three Forget-me-nots extensively used for the supply of the flower-shops—the common brook-side Forget-me-not (*M. palustris*), the early one (*M. dissitiflora*), and the Wood Forget-me-not. The Azorean Forget-me-not, with its dark blue flowers, would be equally useful, if it were as hardy and as easily grown generally.

— AMONG Alpine flowers now in bloom, the gem is the delicate sky-blue *Omphalodes Lucilise*, the flowers of which are much larger than those of the old *Omphalodes verna*, and the habit most graceful. It is somewhat difficult to manage; but Mr. Wilson supposes that the difficulty is mainly owing to the fondness of slugs for the plant. Since surrounding it with one of the perforated zinc protectors alluded to at p. 461, not a leaf has been touched, and the plants are now growing and flowering vigorously.

— At the Alexandra Palace Flower Show, which took place on the 6th inst., a very distinct and handsome Alpine *Auricula*, named "William Bragg" (Turner), was awarded a certificate of merit, a distinction so beautiful a flower well deserved. The variety in question is what is called a "pin-eyed" flower; that is, the style or pin protrudes beyond the thrum or cluster of stamens, and florists of the old school have long considered this a fatal defect, the result being that hundreds of lovely flowers of this class have been sacrificed during the last half century. We are therefore glad to see this absurd rule thus practically abolished by judges who are themselves *Auricula* growers.

— Mr. MOORHEAD, writing to us from Bina Gardens, South Kensington, says—It may be of some interest to your readers to know the relative order in which the shrubs bloom in the beautiful parks and gardens of London. I will not encroach upon your space by giving the different lists from which my conclusions are drawn; suffice it to state the result, viz.:

- 1st. St. James's Park.
- 2nd. Battersea Park.
- 3rd. Kensington Gardens.
- 4th. Botanic Garden, Chelsea.
- 5th. Ranelagh Gardens, do.
- 6th. Regent's Park.
- 7th. Victoria Park.

As the seasons roll on different climatic conditions may produce different, though probably not much, varying results; I speak of the spring of 1876.

THE FRUIT GARDEN.

SETTING FRUIT BLOSSOM UNDER GLASS.

MANY different opinions have lately been advanced on this subject; some have achieved the greatest success by means of a liberal use of the syringe on the expanded blooms, while such practice in the hands of others has resulted in failure. How is this to be accounted for? Very easily—on the one hand the trees have been treated in a natural manner, and on the other quite the reverse. A few years ago, as I passed through the fruit-houses in a garden in which Vines, Peaches, and Nectarines were grown in pots, the day being very hot, I observed, about three o'clock in the afternoon, that the foliage was mostly drooping from want of water, and that a fine crop of red spider was brooding. I asked if it were usual to allow fruit trees to droop in that manner, and was informed that they were never watered till shutting-up time, at four o'clock on hot days. Treatment of this description impairs the feeding power of the roots, as well as prevents the perfect formation of the flower-buds; after which neither the syringe nor camel-hair brush will produce the free setting of the fruit. Another bad practice is turning the plants out-of-doors and exposing them to the hot sun without sheltering the pots, thus giving them a good baking to produce fruit-buds. Under such treatment most kinds of stone fruits will produce plenty of bloom the following season, and it may look healthy to a casual observer, but most of it will be imperfect; owing to the pots being exposed to the sun, the roots get so scorched as not to be in a condition to supply the demands made upon them, and of course the bloom falls to the ground in spite of the syringe or other preventive. The same thing happens in the case of fruit trees planted in inside borders—that is, if they are allowed to become dust-dry after the fruit is gathered and the growth completed. Such extremes should always be avoided; the roots should never be allowed to become dust-dry, nor yet sodden and sour with too much water. In preparing for next year's crop, every shoot should be equally balanced, rubbing off all the rank-growing ones that can be spared. Pinch the point of any shoot taking an undue lead, which will strengthen the weaker growths and keep the tree equally furnished. Give a plentiful supply of water to the roots when required; and if the trees be heavily loaded with fruit, supply them regularly with weak manure-water, which is preferable to occasional strong doses. Use the syringe freely overhead in fine weather, in order to check red spider. When the growth is completed and the fruit gathered, the plants in pots will be benefited by being placed out-of-doors in an open airy situation on a bed of clinkers, or any other open material which will admit of free drainage, filling up between the pots with spent tan or leaves, or any other suitable material that may be at hand, which will shelter the sides of the pots from the hot sun. Supply them regularly at the roots with water, and an occasional shower overhead, given with the syringe or garden-engine, during hot, dry weather, will keep the foliage clean and plump up the buds. Should the autumn prove wet before they are housed, place two plates against the tree, so as to form a ridge, which will throw the rain off the roots and admit a free circulation of air. Supposing the Peaches and Nectarines to have been housed and brought on gradually in a genial, moist atmosphere, with as little fire-heat as possible, and the buds begin to open freely about the middle of February, continue the mild, moist atmosphere with the addition of a little front ventilation in accordance with the state of the weather outside; this keeps the air in motion and sweetens the atmosphere, which is beneficial to the well-being of the plants. Treated in this manner, the syringe may be used with advantage, but the same or better results may be attained by leaving Nature to take its own course. The treatment just recorded is equally applicable to the Vine, except that it requires a more liberal amount of heat during the blooming season, particularly the shy-setting varieties of it, bearing in mind that no syringing overhead should be allowed after the buds have broken—a practice pursued by some, but productive of evil rather than good results.

JAMES SMITH.

Waterdale.

STARTING POT VINES EARLY IN AUTUMN A DISADVANTAGE.

I CANNOT agree with Mr. Muir's remarks on this subject (see p. 328). Cultivators will, I apprehend, require more than hearsay evidence before they depart from a practice which has so long been established by facts. The point with which I have particularly to deal is "time." If Mr. Muir can start Vines at Christmas, and have them as forward as those started seven weeks previously, I should consider such a feat little [short of a phenomenon in Grapes growing. Such practice, if successful, would effect a great saving in fuel. The fruiting of Vines in pots is, I apprehend, to save permanent Vines from being forced during the "dark days;" and I have yet to learn that thoroughly well-ripened canes grown in this way will not yield equally well to the influence of heat and moisture in the month of November as at Christmas. Let me be thoroughly understood; there must be a thorough preparation for such work, for the man who depends upon half-ripened canes had better save his time and fuel. There is not the stamina in them to yield anything like a return for the trouble involved in the production of fruit so early. Some of my pot Grapes were ready for cutting a month ago, and I will endeavour to briefly detail my practice. I like two-year old Vines for fruiting in pots, as I can ripen them earlier than yearlings. I raise a few eyes every year for pot-work; the first year the final shift never exceeds an 8-in. pot; and at the end of the season canes are made as hard as a deal board; the second year they are treated liberally, and get a sharp season of growth and a thorough ripening in the full heat of the sun. Some growers never turn such Vines out-of-doors, but I do and for the following reason:—When I am satisfied that the ripening process is thoroughly effected I turn the pots down behind a north wall for about six or eight weeks, and I believe that when the Vines are taken indoors they are readier to respond to the call made upon them by the application of heat and moisture than if they had been otherwise treated. I think it is only reasonable to expect that a Vine taken from behind a north wall will be more susceptible to the influence of heat than one which has been grown under glass all the season, and this I consider to be a point gained in early forcing where time is the object aimed at. My pot Vines this year were grown as just described; they were started in a bed of leaves on the 1st of November, and were in full flower by the end of the first week in January, and the fruit was ready for cutting on the 5th of April. I may add that I have only taken from three to four bunches of each Vine; the berries were a fair size and as black as Sloes, with a beautiful bloom. I have now a question to ask of Mr. Muir. The first set of Vines, which were started in November, bore ripe fruit, whilst three Vines, started in the same house on 1st January under exactly the same treatment, had their fruit just thinned. Does this agree with Mr. Muir's statements? It is an established fact with me that well-grown pot Vines will stand a sharp heat without showing any diminution in the quantity or quality of their fruit; if Vines will not stand one season's sharp forcing it is the fault of the grower, but upon no consideration am I recommending such treatment, unless where proper preparation has been previously made. When Mr. Smith, of Waterdale, St. Helens, can succeed in producing such beautiful Grapes as he does in March, no one, I think, need despair, surrounded, as he is, by the effluvia arising from the various chemical works in the neighbourhood, and I should like to have his experience on the subject under discussion.

W. HINDS.

Otterspool, Liverpool.

Rust on Grapes.—"G. H. G." (see p. 422) is mistaken in considering that cold draughts are more likely to cause rust on Grapes than sulphur. Rust occurs when the Vines are in bloom or when they are setting, a time when cold draughts should always be avoided. If the hot-water pipes have been sulphured, even if it should have been done some years ago, and the pipes well cleaned before starting the vinery—if they once get overheated when the Vines are in bloom or just setting, rust is sure to be the result. On the contrary, if a genial atmosphere be maintained during the time when the Vines are in bloom and setting instead of a dry parched one, there need be little fear of rust.—JAMES SMITH, Waterdale.

Hybrids between Siberian Grabs and Apples.—Minnesota is the State in which most of these interesting hybrids have been gained. There has been probably not less than 100 varieties of these hybrids under cultivation to some extent by the different nurserymen of this State, most of which gave promise of excellence in some respects, but owing to some of the varieties being subject to blight and others proving more fruitful and of better quality, the varieties having the least merits have been struck off the list from year to year by our State Horticultural Society and large tree planters, till we have about a dozen, possessing all the merits of the best Apples of

Michigan, except in size of fruit, while some of them fall but little short in this respect. In 1869 I gathered up 100 of these hybrids of Minnesota production, and exhibited them at our State and county fairs. These ranged in size from a small Cherry to that of the Fameuse Apple, and in quality some of them were not surpassed by the best Apples.—J. B. JORDAN, in "Prairie Farmer." [We fancy these hybrids would be likely to thrive in England, and they would add a desirable variety to the Apple store.]

Growing and Training Gooseberries.—What is the best plan by which abundant crops of this valuable fruit may be obtained both in a green and ripe state? Gooseberry bushes as a rule certainly do not succeed as they did many years ago nor Carrants either. Would they do better on walls or trained as espaliers?—L. C. [No difficulty need be experienced in getting abundant supplies of Gooseberries, both in a green state, and also for dessert, in suitable soils and under good management when grown as dwarf standards. The chief point requiring attention is to keep them clear of caterpillars and to prevent birds from destroying their buds in winter and spring. They will likewise bear good crops when trained as espaliers, and in that case are easily covered with nets to keep off birds, and with Fir or Evergreen branches should severe spring frosts be liable to injure them when in blossom. As to training them on walls it is only north aspects on which it would be advisable to plant them, as more valuable fruit trees could be grown on the other aspects. On a north wall the Warrington bears well, and will hang in good condition until the end of September, if netted up from birds.—WILLIAM TILLEY.]

Manuring Orchards.—People often look at trees growing on rocky hill-sides, and argue therefrom that trees can grow without manure. They know that Potatoes and other vegetables must have manure given them or they will not thrive, but they regard trees as a different order of vegetation—something that can thrive and flourish where nothing else would. But, in the case of trees on rocky hill-sides, the land is often anything but poor. The rocks themselves frequently contain valuable mineral matter, which, as the rock decays, is presented in a form that plants can feed upon. Then, whatever vegetation grows among the rocks, remains there to decay, and even leaves and other foreign substances that blow in the crevices and land hollows, formed by the rocks, make a valuable plant food on which the tree thrives. Indeed, trees in apparently poor, rocky places, are really much better off than many trees in orchards, where they are in what appears good land. In more level land trees must be manured. In many cases it is as necessary to the best success that trees have an occasional manuring, as it is that any other crop should have manure. There have been many discussions as to whether manure for fruit trees should be applied broadcast or ploughed in. We would say that for orchard trees there is no rule. It depends on circumstances. If the trees are on ground where vegetables are grown, the manure is, of course, turned in for the benefit of these crops, and the roots of the fruit trees fight with those of the vegetables for some of it, and get it, too. But there are many orchards where there are no crops grown but the trees, and then it is excellent practice to apply manure as a top-dressing at least every other year. In a word (says the "Michigan Farmer") top-dress your orchards occasionally, if you would have them bear an abundance of good fruit; but be not troubled about what you should top-dress with.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.
